Among the facilities required on the New York Terminal Division of the Pennsylvania Railroad was the Railroad Company's telephone service. The line for this purpose forms an extension of the New York-Philadelphia main line, from its point of intersection with the Terminal Division at the east side of the Passaic River near Newark, N.J., and consists of a pole line along the right of way across a continuous five-mile stretch of semi-tidal meadow swamp land known as the "Hackensack Meadows," to the tunnel portal at Bergen Hill, the Hackensack River being crossed midway of the section. The ground surface is covered with a heavy growth of reeds, and the top stratum is a peaty bog, from 8 to 15 feet deep, underlaid with varying strata of clay, fine sand, and mixed sand and clay for very considerable depths. It will be seen, therefore, that the problem was to provide a design of pole which would not only be strong in itself, but which could be set in a stable foundation in a soft and uncertain ground. It was desired to make the line entirely secure against interruption by severe storms or by fires in the swamp reeds. It appeared, under these conditions, that the ordinary type of wooden pole would not be wholly satisfactory, either as regards strength for such a heavy service or safety as regards the frequent meadow fires.

The use of reinforced concrete poles for the purpose appealed to us, but very little reliable data about either the cost or service from such design was obtainable. In Europe the author had observed the quite extensive use of concrete poles, chiefly for electric transmission purposes, but details of their construction were not at hand. These poles are frequently of structural steel covered with a protective coating of concrete, and sometimes are of wood encased in concrete, and much ingenuity has been expended in devising special forms of composite poles, but with what practical success it is difficult yet to say.

Manufacture of Concrete Telegraph Poles, Showing Skeleton Frame Suspended in Place; Frame in Form, Ready for Pouring, and Finished Pole.

The desirability, however, of securing a strong fireproof line across this section of our road was so great that the writer undertook to design in his office a simple form of reinforced concrete pole, which could be manufactured on or near the work and at a cost which would not be prohibitive. Without previous data to go upon the design evolved is somewhat experimental, and probably the notes here given will not be of very great assistance in fixing a precedent for an ordinary telegraph pole, as our conditions called for heavier construction than usually required of such lines. The data, however, is given for what it is worth, as indicating a heavy and difficult piece of construction for a special problem.

There were 202 poles required, spaced from 70 to 135 feet apart, with an average standard spacing of 120 feet, the variations in span being due to numerous railway and highway crossings. The height of the top of poles above the ground also varies for the local conditions from 25 to 50 feet, and the total length of poles from 35 to 65 feet. The loading called for an ultimate capacity of 60 open tele-

* A paper before the Eighth Convention of the National Association of Cement Users.

† Consulting Engineer, Pennsylvania Railroad.

graph wires and two 40-pair telephone cables and one signal control cable. The open wires are of copper, Nos. 7 and 8 B. & S. gauge, and the cables Nos. 13 and 16 B. & S. gauge insulated wire, with a lead covering. The cables are carried by steel messenger wires. The weight of the wires and cables is 10½ pounds per running foot, giving a total loading for the average span of 1,268 pounds per pole, or including cross arms, insulators, brackets and fittings, 1,500 pounds per pole. In addition to this static vertical loading, emergency conditions were assumed of an extra loading of half inch of ice on the wires and a wind pressure of 8 pounds per square foot on wires and 13 pounds per square foot on poles. The stresses under these conditions not to exceed the elastic limits of the wires and of the carrying structures. These assumptions are equivalent to a vertical loading of 7,600 pounds per pole and a horizontal

Concrete Telegraph Pole Line over Hackensack Meadows, N.J.

force of 4,000 pounds exerted one foot below the pole top. The normal sag of the wires at 60 degrees Fahrenheit temperature is 4½ inches and a normal tension of 273 pounds for No. 8 wires and 130 pounds for No. 9. The maximum hot sag at 130 degrees Fahrenheit is 11 inches; the tension in the wires under maximum wind pressure with the ice loading at 20 degrees Fahrenheit is 702 pounds and 470 pounds respectively for the two sizes of wires.

The design adopted is that of a tapering, smooth surface, reinforced concrete pole, square in cross section with chamfered corners and having a taper of ½ inch in 5 feet. The concrete is of 1½:2:4 mixture, assumed to have an ultimate strength in compression of 2,000 pounds per square inch. The reinforcement is composed of mechanical bond bars tied together into a square skeleton frame, and in the complete pole this reinforcement is covered by a one-inch minimum thickness of concrete. The following table gives details of the complete construction.

In order to manufacture the poles economically a yard was established adjacent to the right of way and with side track connections for delivery of materials. The ground was leveled and set with stringer pieces, three feet apart, of old wooden car sills, so as to furnish a convenient surface upon which to erect the timber forms. This yard permitted of the simultaneous manufacture of six poles and the storing in place of 90 poles during the period of seasoning. In the process of manufacture the skeleton reinforcement is first made up, the twisted steel mechanical bond bars being tied together to form a square skeleton frame; this frame is then suspended at the proper height above the ground and the sectional wooden frames put in position around it. The concrete mixture is then poured in and carefully tamped. In this way six poles were made per day and were left in place at least sixteen days to season.

Table of Concrete Poels.

Length, feet	Equivalent pull, 1 ft. from top.	Edge distance for steel.	Area steel.	Extreme Fiber stress in concrete compression.	Unit compression stress in steel.	Weight of pole.	Cubic ft. concrete	Weight of steel, pounds.	Lin. ft. of wire wrapped around pole.

55	4860	1.87	5.00	1832	19155	13000	86.58	1974	490
60	4945	2.00	5.30	1812	19083	15000	101.28	2249	533
65	5020	2.00	5.48	1976	18591	17600	117.23	2575	618

After a number of experiments it was found best to set the poles in pits excavated in the marshy stratum. These pits were generally about 9 feet square and 5 feet deep, and a timber grillage was placed around the base of each pole, and about 5 feet below the top of the ground. This grillage consisted of six track cross ties bolted together and to the pole, and partly planked over by 3-inch rough lumber. The pole, which projected below the grillage and was pointed at the butt, was jetted down by compressed air into the sandy layer, so that the grillage would rest at the bottom of the pit. The pits were then back-filled with rock and clay. Poles on curves are cross-guyed, and the terminal and railway crossing poles are head-guyed with steel cables.

In order to determine the stability of the foundations, as above described, as well as the transverse strength of the pole itself, a test was made of a 55-foot pole set in a 13-foot deep foundation. The test consisted in applying a horizontal pull 39.5 feet from the ground. The breaking load was 4,360 pounds and the point of fracture 20 feet from the ground, at the top of the 32-foot reinforcement bars. The foundation itself was found to be amply secure.

The actual cost of labor and material for manufacture of these poles, reduced to a unit cost for an average length pole of 40 feet, weighing 7,600 pounds, was as follows:

Forms—labor and material	$19.00
Concrete—labor and material	26.50
Reinforcement—labor and material	32.00
Total per pole	$77.50

The above does not include cost of preparing site, engineering, etc., and is for the bare poles (without fittings or foundation timbers). To obtain the cost of the poles erected, there must be added the cost of loading, distribution, foundations and setting, cross arms and fittings, but these items were special to the particular location and would be of little use as a matter of general information. It might be stated, however, that the cost of handling and erecting these heavy poles was considerably more than would be the case for wooden poles; furthermore, care must be taken in loading and unloading them and special appliances are required for their erection.

In the special case in question it was figured that the cost of the line erected complete was not greatly in excess of that of an equally stable wooden pole line, as in order to meet such a condition it would have been necessary to employ "H" frame poles and set them in equally expensive foundation pits. In the case of this line it is interesting to note that the foundations and setting cost considerably more than the poles themselves.

To sum up, it may be said that for the particular case of this heavy line having very difficult foundation conditions, the use of a reinforced concrete pole resulted in a durable, safe and neat appearing construction at little additional cost to that of a wooden pole line inferior in all these respects.

Properties of Metals.

THE EDITOR:

Dear Sir,—I enclose herewith a table which I think should prove of interest to most of your readers as it contains information culled from a great many sources, and should prove a good labor saver in hunting up references, etc. F. TISSINGTON, SHERBROOKE, QUE.

THE CITY AND SUBURBS PLANS ACT.

A step in the right direction has been made by the Ontario Legislature by the passage of the City and Suburbs Plans Act. The clauses of the Act provide that in all cities of a population of 50,000 or over, and throughout a five-mile zone surrounding such cities, the subdividing of areas into building lots, and the locating of highways through such areas must hereafter be in accordance with plans approved by the Ontario Railway and Municipal Board. A copy of this Act appears in this issue of *The Canadian Engineer.*

The growth of towns and cities in Ontario and throughout Canada has been so rapid and the method of laying out building lots in territory adjacent to these cities has been so haphazard that the results to the cities have been rather serious. No definite plan has been adhered to in these sub-divisions, and this has caused great difficulties in providing thoroughfares and transportation facilities when these new areas are annexed to the municipality. Additions to the city's territory have caused increased demand for better transportation facilities, but the lack of connecting streets and main thoroughfares in the new sections has led to endless trouble. The Act as now passed gives assurance that the streets and the general layout in areas hereafter sub-divided will be in accordance with the highways and thoroughfares of the city.

As we have noted, the Act is a step in the right direction. There is still room, however, for legislation giving some oversight or control to the city over a suburb's development. Public improvements, such as waterworks, sewerage systems, street car lines, etc., should be designed so that when they are later connected to the city system there may be a minimum of loss and a maximum of economy.

THE SALARIES OF ENGINEERS.

We have referred many times in these columns to the poor salaries paid by municipalities to their engineers, and, while conditions are improving slowly, there remain many grounds for complaint still. The city of Toronto is by no means the least offender in the matter of inadequate salaries to their engineering staff. Yet, the city, through its City Council, newspapers, and even the engineers themselves, refer to the fact that many engineers have left the city's employ to take positions in other cities at greatly increased salaries. The statement is made, and often reiterated, that Toronto is a training-ground for engineers for other cities. If this is true, and we do not doubt it, the condition of affairs is one to be ashamed of rather than one to express pride in. Heads of engineering departments in Toronto are receiving salaries lower than towns of 6,000 or 8,000 people are paying to their engineers. Assistant heads of departments, men in actual charge of the construction work, are receiving salaries less than the foremen, who are receiving orders from them. Is it any wonder these men leave when the opportunity arrives? Any citizen who makes a statement that the city's engineering department is a training-ground for better positions has little idea of the fitness of things. No worse charge could

be made against the city. If the salary question at the City Hall were adjusted, more efficient work would be done and a permanent staff would be built up. When we consider that assistant heads of departments are receiving salaries of less than $100 a month, and that clerks with no special training or ability are receiving $150 to $200 a month, we can readily understand why so many changes occur in the engineering department.

The City Engineer has not been altogether lacking in blame for this condition, for recently, when the head of one of his departments was appointed to another position, the Council wished to raise his salary and keep him. The City Engineer, however, said that if this man's salary were raised sufficiently to keep him employed by the city, that a number of other increases would have to be made; therefore, he would advise that the salary remain as before. To secure a well-balanced, efficient and enthusiastic organization, each individual man must be satisfied. Therefore, any reorganization of the Works Department of the city of Toronto must include a readjustment of salaries and the payment of sufficient to assure the permanent retention of men experienced in the city's work.

RAIL SPECIFICATIONS.

The standardization of rail manufacture has progressed rapidly during the past ten years, due mainly to the joint action and co-operation of manufacturers and engineers. In a recent issue of a contemporary, Mr. W. C. Cushing draws attention to the test conditions as imposed by the various engineering associations, and it is to these test conditions that a good deal of the advance in the perfection of rail-making is due. It must be added, however, that the frequent failures of rails noted, with the attendant terrible consequences, leaves much to be accomplished still. Mr. Cushing states that specifications for steel rails have always consisted of three general parts: chemical requirements of properties, physical requirements, and the details of manufacture. Up to the time the Rail Committee of the American Railway Engineering Association recommended certain specifications in 1901, the various railways emphasized one or more of the above three parts, according to their individual preference or experience. Some almost ignored the chemical requirements, others were more or less elaborate in their physical requirements, while some barely touched upon the details of manufacture, and others treated the subject quite elaborately. Since that time, by the devotion of considerable time and much careful study to the question, the American Railway Engineering Association have progressed towards the adoption of standard specifications for rails. It has now a set of proposed specifications which embody the best knowledge of the subject, and these are being changed from time to time in the light of new experimental investigation. New methods of testing or improvements on these methods are used to determine the physical property, while practically no change has been made in the chemical requirements from the standard specifications of the rail manufacturers. The railway engineers prefer to subject the finished material to such tests as will cast aside the defective rails, and this accounts for the additional tests over those in use some years ago. A marked improvement is apparent in the rails being laid since the adoption by the manufacturers of the new specification.

EDITORIAL COMMENT.

Now that the first wave of sympathy and criticism regarding the disaster to the Atlantic liner, Titanic, has passed, we are able to form some judgment and to hear the candid opinions of men qualified to speak on the subject. There is little doubt that the sinking of the vessel will have the effect of placing some restraint on the size of future ships. When the region of extreme sizes in engineering structures is reached, experience and precedent alike are at fault. There was a good reason for the project of building the Quebec bridge, but there appears to be little reason for the construction of 50,000-ton liners. The disadvantages of such large vessels are becoming apparent, but until a general public feeling is expressed against their construction, they will continue to be built.

* * * *

The utilization of the peat resources of Canada is becoming an important matter as the cost of coal increases and the liabilities of coal strikes remain. We noted some time ago the foundation of a Canadian Peat Society. The objects of the Society, formed about two years ago, are to gather and disseminate information concerning peat and peat deposits and products, for the purpose of educating the public as to the value of these products, to encourage the drainage and development of bog and peat land for agricultural purposes, and generally to adopt such measures as may aid in the establishment and the sound basis of a peat industry in Canada. With the above objects in view, the Society are now issuing a quarterly journal, which is to be a source of accurate information and of encouragement and aid to peat men in general. This Society is deserving of the hearty support of every Canadian interested in the development of our latent resources.

* * * *

Denver, Colorado, has made a move towards lessening the smoke nuisance. A smoke abatement commission of five members to advise the mayor and the smoke inspector is provided for in a bill drawn up by the city art commission. The bill is more drastic in its conditions than previous smoke ordinances. The following clauses may be referred to: for every alteration made in the chimney of any kind a permit is required; before a heat or an electric generating plant of any kind is constructed, repaired or altered in any manner, the plans and specifications must be submitted to the smoke inspector; persons failing to take out permits to construct or repair furnaces, etc., will be fined $25 for each day of the construction or alteration; persons who cause dense smoke to rise from heating plants, locomotives, etc., are liable to a fine of from $10 to $100 for each offence. While the above conditions are rather rigid, if conditions in Denver are as bad as in some of our Canadian cities, it is quite certain that a severe regulation, strictly enforced, is required. It is time that adequate inspection and enforcement of smoke by-laws and regulations were made.

COST OF TRACK-LAYING ON THE ERIE RAILROAD.

An article by H. C. Landon, Division Engineer of the Erie R.R., in the Erie Railroad Employees' Magazine, gives some figures of cost on track laying under the old methods, which may be of use in determining whether or not the use of a track-laying machine will be economical. Mr. Landon writes as follows: In 1905 and 1906, while Engineer M. of Way of the Buffalo & Susquehanna R.R., I was in direct charge of all track laying, ballasting, etc., between Wellsville and Buffalo, and had, in fact, previous to this time, charge of all the track laying of the Buffalo & Susquehanna system from 1898, about 110 miles in all. I have not the data of cost of this work, except that with the low price of labor, the cost per mile, including rental of engines, cars, etc., and the cost of labor, it did not exceed $275 per mile. As much as 5,700 ft. of track had been laid in a single day with about 65 men, through the winding valleys of the branches of the Susquehanna River, south of Wharton, Pa., and the average kept up to very close to a mile per day, where any considerable grade was ready ahead of the track layers-

On the line between Wellsville and Buffalo there were a large number of bridges to be constructed, as the track laying advanced, the steel for the bridges being brought over the new line, so that the track layers hardly became organized for rapid work before they were stopped for a period of two or three days to two months, while the new structures were being erected. During this period the track layers were ballasting the new track, or engaged in completing unfinished track on troublesome fills. The laborers, especially the spikers and members of the iron gang, had had previous experience, and had in general become quite expert in the work.

About one-third of the men were Hungarians and the balance Italians. No natives were employed. While at first the Slavs were decidedly the better laborers, some of the Italians became expert in spiking and in handling the rail, so that spike gangs and iron gangs were made up of Italians and Hungarians, creating a rivalry which expedited the work considerably.

Two truck gangs were always employed, passing each other by using a portable turntable, or by lifting the heavy truck body from the wheels. Good camp cars were provided, and also a well-equipped blacksmith's shop. A combined gasoline engine and pump, and a tank of 10,000 gals. capacity—which could be quickly taken down and erected—formed part of the equipment, so that the track-laying engine could be kept close to the work.

The longest stretch of grade which was ready for the track and where no large bridges intervened to delay the work, was between Belvidere and Belfast and White Creek bridge. On this stretch it was demonstrated what a track-laying gang could do when the organization was well in hand. This work does not compare with feats in the west over a level country, but among the winding roads of the east, it does compare very favorably. The biggest day's work on this stretch was 5,000 ft. and the average for the 6 miles was 4,600 ft. per day.

North of White Creek bridge, 5,900 ft. was laid on July 2, 1905, including delay of several hours placing a small bridge at Transit Bridge. The average for this one gang during the time employed was about 4,400 feet per day.

Other smaller gangs were employed out of Arcade and Hamburg, working north and south to reach important large structures nearby, and while these did not accomplish as much in a single day, the average of about 50 ft. per man was accomplished.

The track-laying gang was made up about as follows:—

1 foreman, at $4	$ 4.00
2 assistant foremen, at $3	6.00
12 spikers and nippers, at $1.50	18.00
36 trackmen, at $1.50	54.00
2 tie tiers, at $1.50	3.00
2 tie spacers, at $1.50	3.00
1 spike puller, at $1.50	1.50
4 bolters, at $1.50	6.00
2 rail unloaders, at $1.50	3.00
4 tie unloaders, at $1.50	6.00
1 water boy, at $1.25	1.25
Total	$105.75

Behind the supply train, full tie-ing:

1 foreman, at $3	$ 3.00
24 laborers, at $1.50	36.00
1 timekeeper, at $2	2.00
Total	$ 41.00

At storage yard, loading rail and ties:

1 foreman, at $3	$ 3.00
24 laborers, at $1.50	36.00
Engine and crew, at $40 per day	40.00
Total	$ 79.00
Total in all	$225.75

The average amount of track laid per day was over 4,000 ft. At 4,000 ft. per day the cost per mile would be $297.97. As much material, rail, ties etc., was received while track laying was in progress, the expense of rehandling in the supply yard was avoided.

The auditor's books, when rail laying was completed between Wellsville and Buffalo, indicated the entire cost of labor for laying 98.1 miles of track to be $29,515.45, or $300.85 per mile. Of this 98.1 miles of track, 85 miles was main track and the balance sidings, "wye" tracks, and passing tracks.

The labor cost included the building of the turnouts, etc. This is the total cost of labor, including engine and train crew, fuel, supplies and rental of engine and of office force.

All rail laid was 80-lb. A. S. C. E. section.

RAILWAY PLANS PREPARED.

The Canadian Pacific Railway will expend a large amount of money at St. John this year. Mr. D. McNicoll, general manager was in the city recently and stated that plans were prepared for an additional elevator with a capacity of 2,000,000 bushels, and that as fast as the federal government constructed the sea wall, upon which work will be begun this spring, the company would fill in the shore lots at West St. John and lay additional tracks. He said that the company could handle twice as much traffic at St. John as it is doing at the present time if the terminal facilities at the port were able to take care of it. The company during the winter built extensive freight sheds on property that it acquired at the head of the harbor. Mr. McNicoll says much more must be done at that point in order to handle their local and provincial business. The company will spend considerable money during the summer on their railway lines in New Brunswick.

PROGRESS IN CANADA IN BIOLOGICAL METHODS OF SEWAGE DISPOSAL DURING THE LAST TWENTY YEARS.

By Willis Chipman, C.E.

Twenty years ago the principles underlying the biological methods of sewage treatment were attracting the attention of municipal engineers in Great Britain, experiments were being carried on, and phophecies being made, echoes of which were to be heard in Canada.

Broad irrigation was then the accepted standard in Great Britain, although the nitrification theory of purification was not so well understood as to-day. Profitable crops were too often the desideratum rather than sewage purification, but on the whole the results were satisfactory. Broad irrigation had also been adopted at Paris, France; Berlin, Germany, and many other cities. The land necessary for broad irrigation was not always available, however, and many cities and towns in Great Britain and in Germany had adopted chemical precipitation methods, but, generally speaking, its advocates were experimenting continually.

The failure to produce a marketable fertilizer from sewage sludge by chemical precipitants stimulated inventors, and many processes were invented, patented, and advertised to the public.

About 1871 filtration through charcoal was tried in England, as a result of which the conversion of the ammonia and the nitrogen or organic matter into nitric acid was recognized, and the theory of intermittent filtration first brought to the attention of engineers.

The State Board of Health of Massachusetts undertook a series of experiments in sewage filtration in 1886, as a result of which intermittent downward filtration was adopted by many towns, and by 1891 this method of sewage purification may be said to have become the standard in New England.

In the Province of Ontario the first practical attempts at sewage purification were made at the Asylum for the Insane, London. The works were designed by the late Col. George E. Waring, of New York, an engineer of international reputation, and constructed by the Provincial Department of Public Works. The sewage was intermittently applied to channels or ditches, well underdrained, but it was then called a flat-bed-irrigation system. The agency of bacteria was, however, recognized in descriptions given of the system.

These works have been in continuous operation since 1888, and the results have been eminently satisfactory, due largely to the labor available for properly operating the beds, and for cultivating the crops.

In 1890 experiments and tests were conducted at the Provincial Institute for the Deaf and Dumb at Belleville with a patented system known as the "Condor" system, but the results were not satisfactory. The chemical solution in this process was merely sulphate of iron.

In the following year the "Ferrozone 'Polarite'" process, another patented system, was experimented with at the Ontario Agricultural College, Guelph. Upon the recommendation of the late C. H. Horetzxy, of the Provincial Public Works Department, this system was subsequently adopted at the Mimico Asylum, at the Institute at Belleville, and at other Government institutions throughout the Province.

In 1892, the town of Berlin, Ontario, constructed sewage purification works, which were no doubt the first municipal works in Canada.

The population of the town at this time was about 7,500. Three miles of sewers on the separate system conveyed 125,000 gallons daily by gravity to a plot of land secured for disposal works. It was estimated that over fifty per cent. of the flow represented subsoil infiltration.

Of the twenty acres purchased, five acres at least were unfit for use. Eight acres were originally laid out into four flat beds, cosely underdrained, and separated by embankments.

For three or four years the results were quite satisfactory, notwithstanding as much attention appears to have been given to the raising of crops as to the treatment of the sewage. During the winter months the sewage was permitted to flow directly to the small stream with a volume of three cubic feet per second, and only one attendant was engaged in the summer to apply the sewage to the beds in rotation.

In 1896, the Provincial Board of Health investigated certain complaints of riparian owners below, and four years later a small septic tank was added, also two filter beds for experimental purposes.

In 1894, the town of Waterloo followed the example of Berlin and constructed several beds for sewage treatment.

In 1896-97 the city of Hamilton constructed chemical precipitation works at Wentworth street, and in 1898 similar works were constructed at Ferguson avenue, since which they have been in continuous operation. These works were the first municipal precipitation works in the province. The sewage is precipitated by carbonate of lime and sulphate of alumina, the sludge pressed by Johnson presses, and the resultant cake sold or given away to market gardeners, or burned, according to the supply and demand.

Deodorants and disinfectants have been experimented with in several places, but Hamilton has adhered to precipitation, and the satisfactory results are due largely to the original design of the works. The effluents may not be non-putrescible, but the grosser solids are removed.

Of the various proprietary processes experimented with in England, one of the first to receive attention here was the "Amifies" process, but it does not appear to have been adopted at any place in Canada. The "Porous Carbon" system was experimented with, but the results were not considered as satisfactory in either case.

The "International System" of purification by the use of "Polarite" and "Ferrozone," having been adopted at several of the provincial institutes, was thus brought into public notice. A company soon took advantage of this and rosy pictures were painted by promoter artists at Toronto, Stratford and London. In the latter city, in 1898, the system would have been adopted for treating the sewage of the entire city if the engineers acting for the city had not pertinaciously opposed the scheme.

The parent company of the International system was organized in England, and a subsidiary company at Detroit, Michigan, from which point Canada was exploited. Several towns in the United States adopted the system to their sorrow, the most notable instance being Madison, Wisconsin.

After a few years' contributions had been paid to the parent company for supplies of Ferrozone and Polarite, the Provincial Government decided to experiment with sand, gravel, etc., and made the discovery that with selected materials the results were quite equal to those obtained with Polarite and Ferrozone. This process then passed from the Canadian stage of action, to be succeeded by the Septic Tank System, promoted by a syndicate. The claims made for this newly discovered method of sewage treatment were little short of miraculous, and immediately attracted the at-

* Presented at Annual Meeting of Canadian Public Health Association, Montreal.

tention of sanitary authorities in Canada, but it does not appear that any tanks were constructed by municipal authorities in this country prior to 1901.

At Berlin a second investigation was made by the Provincial Board of Health in 1901, the evidence demonstrating that the beds were of insufficient capacity to treat the flow, which had increased to 350,000 gallons of very strong sewage per day. The beds were found to be overworked, waterlogged, full of sludge, and the authorities were at the same time endeavoring to raise crops.

In 1902 the Legislature appropriated $2,000 to carry on experimental work in the interests of the municipalities in the province, which experiments were made at Berlin. As a result the town decided to construct:—

(a) Two septic tanks.

(b) To pump the affluent of the tanks.

(c) To adopt intermittent downward filtration.

Fourteen acres of high gravelly land subdivided into sixteen beds, were selected adjoining the original "Sewage Farm," as the public persisted in calling the works.

In Dr. Amyot's report upon the Berlin experiments of 1902, the system of treating sewage by contact beds was clearly described, as well as the results of experiments with effluents from septic tanks, Stoddard trickling filters, and Intermittent sand filters.

In 1900-1901 the city of Stratford constructed Sewage Disposal Works, comprising intermittent filtration beds, which were soon overworked and outgrown. Additions were made in 1904-1905 and a septic tank constructed.

Ten years ago four municipalities in the Province of Ontario had constructed sewage disposal works:

(1) Berlin—Filtration beds, 1892. Experimental septic tanks and two small filter beds, 1901.

(2) Waterloo—Filtration beds, 1894.

(3) Hamilton—Chemical Precipitation Works, 1896-7.

(4) Stratford—Filtration beds and small septic tank, 1901.

The sewage from several provincial institutions was also being satisfactorily treated.

Two or three experimental septic tanks had been constructed, but the boom of the next decade had not commenced.

As a result of a series of experiments carried out by Mr. D. Cameron, the city surveyor of Exeter, England, a syndicate was formed and patents secured in Great Britain, the United States, Canada, and other countries throughout the civilized world for the septic tank system. By 1900 the city of Exeter had become a Mecca for engineering pilgrims, and within a few years Cameron tanks or similar tanks were being constructed not only throughout Great Britain but elsewhere, and generally without consulting the Cameron company. This company claimed the following advantages for their system:—

1. The non-production of sludge.

2. An effluent in the best condition for irrigation or filtration.

3. Filters were recommended by the company to purify the tank effluent.

4. A process free from nuisance.

5. Automatic and absolute reliability in working.

6. The first cost was within the reach of all communities.

7. Working expenses were practically nil.

It is not surprising that the Septic Tank System especially attracted attention in Canada, where climatic conditions were more severe than in Great Britain, and the problem of sludge disposal not as well understood.

The first municipal septic tanks to be constructed in Canada were probably the small ones at Berlin and at Stratford.

A larger tank was built at Stratford in 1904, and in the same year two tanks were built by the city of Guelph. The following places constructed septic tanks between 1904 and 1911, approximately in the order given:—

Peterboro, Toronto (Woodbine area); Vancouver, B.C. (in part); Regina, Sask.; Moose Jaw, Sask.; Berlin (No. 2); North Bay, London, Woodstock, Brampton, Barrie, Vernon, B.C.; St. Thomas, Guelph (No. 2); Haileybury, New Liskeard, Orillia, Oshawa, Bridgeburg, and probably other places.

Hundreds of smaller tanks were also constructed for public institutions and private residences, of which there are no records.

In 1910 the Cameron Septic Tank Company, of Chicago, threatened suit against a number of municipalities in Canada for infringement of patents, which had been declared valid by the Superior Courts of the United States, although it would appear that in Great Britain the patentees did not press their claims for royalties.

The most important claim of the company, the non-production of sludge, was soon proven untenable. The discovery was also made that it was not essential that the tanks should be made air tight, and the light excluded, also that the utilization of the evolved gases was more than offset by the risks from explosions.

The Canadian septic tank boom of the last ten years has commenced to subside, but engineers have profited largely by the experience gained.

The removal of part of the matters in suspension renders the sewage more amenable to further treatment and prevents the clogging of beds and filters. The refuse from certain manufactories, such as sugar refineries, breweries, etc., may, however, neutralize this effect by rendering the sewage acid.

Many of the tanks constructed during the last five years have been more correctly called sedimentation tanks, sludge removers, rather than sludge digesters.

The "Imhoff" tank is at the present time prominently in the eye of the public, due largely to the characteristic energy of the promoters of a patented process or article. Dividends must be earned by royalties paid.

The irrigation beds at the London Asylum, at Berlin, Waterloo and Stratford, were practically identified with the downward intermittent filtration system of New England.

The contact bed system evolved from the above system has not had the popularity in Canada enjoyed by the filtration beds or by the septic tank system, owing largely to the expense involved in properly applying the sewage. Contact beds were constructed by the city of London in 1901, by Stratford in 1904, and by Geulph in 1910, also by the city of Toronto at Woodbine avenue, in connection with the Cameron septic tank installation.

Hydrolytic tanks do not appear to have been adopted by any municipality in Canada, but experiments were to have been made at Edmonton in 1910, the results of which should soon be made public.

Percolating and sprinkling filters are now being adopted by a number of municipalities throughout Canada, but none are as yet in operation so far as the writer is aware, excepting the percolating filter of the Stoddard type at Vernon, B.C.

At the present date the engineers favor tanks for the removal of the grosser solids by sedimentation, the treatment of the effluent upon filters, and the disinfection of the filtrate after a second sedimentation.

By the end of the decade now dawning, every inland city and town in Canada will probably have adopted some method of sewage purification. Such works must be carried out by the municipal engineer, with the assistance of the chemist and the bacteriologist, and we have much preparatory work to do, not only in educating the general public and their representative councils, but in conducting experiments with systems now in operation and in collecting data in advance of designing and constructing.

PUBLIC UTILITIES.

The problems of the valuation of public utilities have been prominently before the Canadian public, the question of the purchase of the Toronto Street Railway and the Winnipeg Street Railway having been recently discussed.

At the recent International Municipal Congress Mr. Bion J. Arnold, chairman of the supervising board of engineers of Chicago said:

"During the last twenty-five or thirty years the most of the great inventions which have made possible the public utility corporations of to-day came into existence. During the early part of this period inventors were rivaling each other, promoters were doing their best to outwit each other, financiers were doing the best they could to gain in financial profit in promoting various enterprises, or backing different enterprises in order that the financial profit might be realized; so that we might say the first ten years of this period was one of strife on the part of all people interested in the matter—and all were interested in it, inventors, promoters, financiers and the public—they were all interested in the final result.

"During this period franchises were granted to public utility corporations upon easy terms. And perhaps it is well that they were so granted, because the public was desirous of securing the advantages of the public utility corporations, and the public also was without the knowledge as to the terms such franchises should be granted upon. And it took some years of experience in the operation under those corporations and under our modern conditions before those facts could be learned..

"The result was that competitive franchises were granted in cities to lighting companies, electric railway companies, to gas companies, to water companies—seldom, however, to water companies, but sometimes—on the theory that competition was the best thing for all concerned, that the greater the competition the lower the cost of production and consequently the lower cost to the consumer. We have since learned that that meant the duplication of capital in many instances, which has since been consolidated into one large company—usually with a profit to both parties—and the result is that the public is carrying to-day a capitalization upon public utility properties that it never should have been asked to carry, and never would have been, had it not been for this competition principle which was followed at that time. We did the best we knew under the circumstances.

"During the past ten years, however, certain corporations which have been granted those privileges had misused those privileges—I do not say all of them but certain ones had—the resulting overcapitalization and the fixing of rates made the public pay higher than it should. As soon as these conditions became known to the public and the franchises of the original corporations began to lapse, then the day of settlement came. These original promoters of these companies, not having understood what depreciation meant, and furthermore, going upon the theory that when franchises lapsed they would be renewed by the municipalities, and also upon the theory that when it became necessary to rehabilitate the properties, they could issue new securities and additional securities for money to rehabilitate with—I say, going upon those two theories, no allowance was made for depreciation and in many instances not sufficient allowance was made for maintenance—maintenance as distinguished from depreciation, meaning the ordinary upkeep of wear and tear, depreciation meaning the natural wear of the property that must be kept up by maintenance or upkeep, or that wear which comes out of the property, necessitating its being renewed.

"For instance, a car may be bought to-day. You can buy new brake shoes, new wheels, new seats, new mats for the floor, etc., and keep it running. That is maintenance. But when that car becomes obsolete or completely worn out and has to be renewed with another car, then comes in renewal or depreciation. And the difference between the value of the original car and the value of the new car—we will assume that the new car was substituted at the same value as the old one—you must provide sufficient money to buy a new car with. It is that value that I call renewals or depreciation. I say, no allowance was made for this in the original promotion of these enterprises in many instances; in fact, I know of no instance in this country where that was allowed.

"Now, what is the result? We have found ourselves, when these franchises lapsed, with dilapidated properties and no money to rehabilitate them, and so highly capitalized that the companies could not stand additional securities in many instances. That is the situation that confronts numerous corporations in this country to-day. It confronted more five years ago than it does now.

"In some cities the problem has been met and solved. It has been met and solved in Chicago, in Cleveland, they are endeavoring to solve it in New York, Detroit, Pittsburgh, Seattle and San Francisco.

"There is a fair basis of settlement between the companies and the public. It has taken me about nine years to come to the conclusion as to what that fair basis is in my own mind, and having had more or less to do with these questions between the public and the corporations, first representing one side and then the other, and sometimes both sides of the same case by agreement, I have given it some thought.

"And I have come to this conclusion, that where a corporation has been honestly managed, judiciously managed from the day of its inception to date, notwithstanding the fact that it may have put in horse cars, light rails and had to renew them, so that if you go out and look at that property to-day you will find no value for those cars or rails—suppose it paid the promoters a profit, suppose it paid a discount on securities in order to raise the money to float the proposition at this time—I say, all such things as that, obsolescence, discounts on securities, reasonable promoters' profits, legal fees connected with the organization, things of that character which cannot be found to-day in the property if you go out and look at it and make a value upon it—I say, such things as that are rightfully a part of the original cost of the property and should be allowed to stay in the capitalization of the company until the parties who have put their money into the property have had a chance to earn that money out, with a fair return upon it.

"So I say if you take the records of a company from the date it was organized up to date and allowing a fair return—I would say a good, liberal rate of interest upon every dollar that went into the property up to date, deducting from what you allow the difference between what the company actually took out in dividends and what it ought to have received upon this basis, then the difference left over and above the value of the physical property that you find to-day should be allowed to stay in the capitalization until the company can earn it out.

"In other words, if the company is to be regulated now, as it often is in many instances where public service commissions are in vogue, and this public service commission, or the public, says: 'From now on you can earn a fair return upon the real value of your property, or upon some valuation'—in other words, 'You are not going to be allowed to make excessive profits any longer, we are going to regulate you from now on'—I say that under such conditions the company has a right, and has a right to demand, that it be allowed to earn a liberal return upon the real money that was put in from the date that the money went in up to date, and that even from this time on after the rate of return is agreed upon between the public body and the public corporation—call it six per cent. if you choose—that all over and above that six per cent. shall go into an amortization fund to gradually retire the difference between that real value of the property as it exists and this obsolescence, promotion fees, etc., which I have named, so that eventually the property will be paying a return simply upon the value of the physical property performing the service.

"Now if I make that clear, suppose that a company has $100,000 worth of physical property to-day. Suppose it has shown it has put in $120,000 in real money, that is, on this basis I have figured, say at eight per cent. from the time it went in. There is a difference then of $20,000 that there is nothing to represent at the present. I say, the company is entitled to earn a return upon that $20,000, in addition to the real value of $100,000, at six per cent., we will say, and to continue to earn it upon that, and all that it earns over that six per cent. shall go into a fund to gradually retire the $20,000 I have mentioned, so that finally the property is paying a return simply upon $120,000 worth of property. The best way to do that is gradually to increase the property to the amount of the $20,000 by gradually putting that money into real physical property."

IMPROVEMENT OF PUBLIC HIGHWAYS ACT.

The amendment to the Ontario Act to aid in the Improvement of Public Highways, will be of interest to engineers. The following are the changes which are of importance:—

The sum of $1,000,000 is set apart out of the consolidated revenue fund to aid in the improvement of public highways.

The said sum shall be in addition to any sum heretofore set apart for the like purpose, and shall be applied as provided by the Act to Aid in the Improvement of Public Highways, passed in the seventh year of the reign of his late Majesty King Edward VII., chapter 16, and amendments thereto, and subject to the same terms and conditions as the fund set apart by that Act.

Section 2 of the said Act is amended by adding thereto the following subsections:

(a) The council of every county in which road improvements are undertaken under this Act shall by by-law designate an engineer or some other competent person subject to approval by Minister of Public Works to act as county road superintendent under the direction of the council.

(b) No grant shall be made to any county under this Act until subsection a has been complied with.

(c) The county road superintendent shall place some competent person as foreman or inspector in charge of any work which it is impossible for him to personally oversee, and it shall be the duty of the foreman or inspector to see that the work is properly carried out.

(d) No member of the council of the county and no member of the council of any local municipality in the county shall be appointed or act under subsections a or c or be employed by the county road superintendent in any capacity, and any such member who is appointed, or who acts or is employed in contravention of this subsection shall be disqualified from sitting or voting in the council of which he was a member at the time of his appointment or employment.

The treasurer of every county shall, before the first day of March in each year, make up and transmit to the Minister of Public Works a detailed and audited statement of all expenditure upon, or in connection with, county roads or bridges for the next preceding calendar year. The statement shall be in such form as the Minister of Public Works may direct. The treasurer shall forthwith publish the statement at least once in a newspaper, published in the county town. The clerk of the county shall procure not less than one hundred copies of the statement and shall deliver or transmit by post one of such copies to each of the electors who shall first make request for the same.

Section 6 of the Act is amended by adding the following: "Or the council instead of raising money by debentures may provide the money required out of county funds, or by an annual county rate in the manner authorized by the Municipal Act, and all the provisions of this Act shall apply to any moneys heretofore or hereafter so provided as fully as if debentures had been issued, whether a by-law transferring such moneys to a special account under this Act has or has not been passed."

Section 12 of the Act is repealed and the following substituted therefor: "All highways designated and assumed by a county council in accordance with section 2 of this Act, except as in subsection 3 of section 2 otherwise provided, shall be maintained and kept in repair by the corporation of the county in which such roads are situate, and in all cases of doubt or dispute as to what constitute works of maintenance or repair, and what constitute works of construction and the purchase and maintenance and repair of road machinery, plant and equipment, properly chargeable under this Act, the decision of the Minister of Public Works shall be final; provided that after the expiration of three years from the final construction and completion of the county system of roads, which shall be so declared by the Minister of Public Works, the county council may, with the approval of the Lieutenant-Governor in Council and of two-thirds of the minor municipalities in the county expressed by by-law, declare that such system of county roads shall, on the 1st of January following, revert to the local municipalities in which the same are situate, and such roads shall thereafter be maintained in the same manner as township roads."

Where it is found by the Minister of Public Works that any highway assumed by the county council under the Act, has ceased to be, or for some other reason is not of sufficient importance to be constructed and maintained as a county road, such road or section thereof may be struck off the approved plan of county roads, by the Lieutenant-Governor in Council, and such road or section thereof shall thereupon revert to the local or township municipality in which the same is situate.

The Act is amended by inserting therein the following section:—

(1) The Minister of Public Works may arrange with the corporation of any local municipality for the construction or improvement therein of an object-lesson or experimental road, or of more than one such road.

(2) The Minister may lay out, construct, improve and complete any such road and the Public Works Act shall apply to anything done by him under this Act.

(3) The cost of material, labor, special engineering or other services, plant, machinery and equipment and the repair and maintenance of plant, machinery or equipment in or about any work undertaken by the Minister under this section or incidental thereto, shall be paid out of the fund set apart under this Act, upon the certificate of the Minister and for that purpose accountable cheques may from time be issued against such fund in favor of the Minister, upon his requisition therefor.

(4) A road shall not, by reason of its having been constructed or improved under this Act, become or be the property of the Crown, but every such road after its construction or improvement shall be under the jurisdiction of the council of the municipality in which it is situate and shall be maintained and kept in repair in the same manner as other roads in the municipality.

When any highway leading to, or adjacent to any city or town separated from the county is widened, strengthened, reconstructed or otherwise improved or requires the expenditure of a greater amount for maintenance and repair to meet the requirements of increased, heavy, constant or other extraordinary traffic to and from such city or town, beyond the requirements which, but for the existence of such city or town, would be deemed those of a standard highway for the locality, the corporation of such city or town by by-law passed with the assent of at least two-thirds of the members of the council thereof may agree with the corporation of the county to contribute such additional cost, or a proper proportion of the cost, or that the amount of the contribution of such city or town shall be determined by arbitration under the Consolidated Municipal Act, 1903, and may, without the assent of the electors, provide by by-law for the issue of debentures payable in not more than twenty years from the date of the issue thereof to raise the amount agreed upon or awarded, or may agree with the corporation of the county for the payment of such amounts in annual instalments to be raised by annual special rate upon the rateable property in the city or town.

The council of any county may assume as a county road under this Act, any main or leading road or roads through or within such county, and where such road or roads do not serve all townships equally, the county council may, with the approval of the Minister of Public Works, omit from assessment any township or townships through which such road or roads do not pass, or may assess any or each township through which such road or roads pass for a larger or smaller amount in order to equitably assess the cost; or the council of any county in which a system of roads is established may, upon the application of a township council, and with the approval of the Minister of Public Works, levy a special rate upon the township for the construction, improvement or maintenance of the county road or roads within such township.

SUMMER SCHOOL.

Announcement is made of the twelfth annual six weeks summer school of the College of Engineering of the University of Wisconsin, which opens on the twenty-fourth of June.

Courses of instruction and laboratory practice are offered in electrical, hydraulic, steam and gas engineering, mechanical drawing, applied mechanics, testing of materials, machine design, shopwork and surveying, in addition to which subjects may be taken in the College of Letters and Science.

For bulletin, address F. E. Turneaure, University of Wisconsin, Madison, Wisconsin.

RAILWAY, TELEPHONE AND OTHER POLES.

The statistics for the poles purchased during 1910 in Canada were obtained from the telephone, telegraph, electric light and power and electric and steam railways operating in Canada. Reports were secured from 559 companies, about 89 per cent. of the total number in operation, by Mr. H. R. MacMillan, of the Forestry Department, Ottawa. Electric light and power companies numbered 291, telephone companies 161, steam railway companies 62, electric railway companies 41, and telegraph companies four. Of these companies 283 operated in Ontario, 94 in Quebec, 39 in Nova Scotia, 35 in Saskatchewan, 27 in Alberta, 23 in New Brunswick, 23 in British Columbia, 17 in Manitoba, 10 in Prince Edward Island, and eight were United States Companies operating in Canada.

The total number of wooden poles purchased in Canada during 1910 was 782,841. The gain over the number reported for 1909 was 434,586, or 118 per cent., due partly to the increased building of steam railway and rural telephone lines. The total value at point of purchase was $1,043,874, which was an increase of $546,822 over the value in 1909. The average cost of poles was $1.39 in 1909 and $1.33 in 1910. The decrease of six cents was due to an increase in the use of short cedar poles by telephone and telegraph companies.

Cedar is the wood most frequently used for poles in Canada, as it is practically the only Canadian wood growing to a convenient pole size which is cheap, easily handled and durable. There were 758,209 cedar poles purchased in Canada in 1910, or 99.2 per cent. of the total. Spruce, furnishing 0.7 per cent. of the total, stands next in the list, having increased in use 175 per cent. over 1909. One-tenth of one per cent. of the total is made up of chestnut, larch and Douglas fir.

The unspecified are, on the average, more expensive because a small proportion of them belong to high length-classes and may include some treated poles. The use of larch has decreased from 14,401 poles in 1909 to 73 poles in 1910. The increased use of spruce accounts partially for this, but the difference is mostly due to the fact that a local telephone company building through a larch district in 1909 in the West used larch poles entirely, but did not build lines in 1910.

Chestnut, hitherto taken with unspecified, was this year separated. All chestnut poles are imported from the United States.

In 1909 pole users were classified under three headings: (1) Telephone and telegraph; (2) steam roads; (3) electric roads, power and light. It was found difficult to properly separate the first two, and in 1910 only two divisions are made: (1) railways, telephone and telegraph, and (2) electric roads, power and light. In 1910, as in previous years, the important class was that including the railway, telephone and telegraph companies, which purchased 744,387 poles or 95.1 per cent. of the total number reported. The use of poles by these companies was 119 per cent. greater in 1910 than in 1909, the increase being all in cedar.

This increase in the use of cedar is also seen in the consumption by electric roads, power and light companies, which used 113 per cent. more cedar in 1910 than in 1909. These companies bought 38,454 poles in 1910, or 4.9 per cent. of the total.

For the steam railway, telephone and telegraph companies the average cost of poles purchased in 1910 was $1.20 per pole; and for electric railway, power and light

companies, $3.98. The difference in these average prices indicates the difference in the size or grade of the average poles suitable for the purposes of the two classes of companies.

In the shorter length-classes, as the 20-to-25-foot class, which composes 75 per cent. of the total number used, it is seen that chestnut is cheapest, then cedar, larch, spruce and Douglas fir. This in itself would explain the great popularity of cedar, for it gives for the money more service than any of the other native woods used.

The prices paid for poles range from $1.01 for chestnut poles 20 to 25 feet long to $7.39 paid for poles of unspecified species 41 feet and over. In general the value of poles advances very rapidly, though not proportionately, with increasing length. The one instance in the 31-to-35-foot class in which spruce poles were bought for 51 cents may be explained by the purchase of the poles in a locality of Nova Scotia where woods have comparatively low value.

Cedar poles appear in every length-class, and form the largest proportion. Spruce also is found in every class, but neither chestnut, larch nor Douglas fir were used over 30 feet in length.

In the thirty-foot class cedar poles are more expensive in Canada than in the United States. Above thirty feet they become cheaper. As seventy-five per cent. of the poles used in Canada are thirty feet or less in length, this means that companies using poles pay more for them, on the average, in Canada than in the United States. At present Canadian users are paying no attention to preservative methods, which in reality increases still more the relative cost. The pole-users of the United States, though paying less for their poles, treat them at a small extra expense, thus increasing the life of the pole and decreasing the yearly cost.

Spruce poles cost more in Canada than in the United States in 1909, except in the 20-to-25-foot class. In this short-length class the cost is 13 cents less per pole in Canada. In the 26-to-30-foot class they cost 35 cents more in Canada than in the United States. In lengths of 31 to 40 feet and over, spruce poles cost from 11 cents to 64 cents more per pole in Canada.

In 1910 poles were exported to the United States and other countries to the value of $74,708. Imports into Canada consisted of 138,285 cedar poles worth $139,486, making an excess of imports over exports of $64,778. These imported cedar poles cost $1.00 per pole and belonged to the 25-foot length class.

Poles, as at present used in Canada, receive no protection against decay in the parts in contact with the soil. The result is that moisture is drawn into the pole, fungus growth is supported and the pole is useless in a short term of years. This unnecessary waste may be done away with and the cost per annum of a pole line may be decreased by treating the poles with certain preservatives. According to information obtained from the Forest Service of the United States, 576,631 poles or 15.4 per cent. of the total used, received such treatment before use in 1909.

In 1908, 10.6 per cent. received such treatment. This increase within a year of nearly 50 per cent. in the use of chemical preservatives shows that the experiment is successful and that it is making poles less expensive. As has been shown, 75 per cent. of the cedar poles used in Canada are from 20 to 40 cents per pole more expensive at the point of purchase than similar sizes in the United States. Evidently it pays United States pole-users to use preservatives with cheap poles. It would, therefore, pay Canada much more to lessen the annual cost of her more expensive poles by lengthening the life of the poles.

It requires from 175 to 200 years to produce the average cedar pole, which, if left unprotected, will rot and be useless in fourteen years. This species, forming 99.2 per cent. of the total number used, grows entirely in the southeastern part of Canada. At present the yearly consumption far exceeds the annual growth. Under the present methods of exploiting the forest, cedar will become commercially extinct in a few years. It is absolutely necessary that some method be adopted to avoid this catastrophe. The easiest means is to adopt the general use of preservative treatment to lengthen the life of cedar and to make other species, not naturally decay-resisting, available for pole use.

Untreated cedar poles, thirty feet long, cost, when the pole is in place, $7.00, and last on the average fourteen years. This is an annual cost of 71 cents per pole, allowing interest on a five per cent. basis. By the creosote brush treatment, which consists in applying the preservative to the pole by hand with a brush, the cost of each pole is raised to $7.20. These poles have a life of seventeen years, making the annual cost 64 cents per pole, or reducing the cost seven cents per pole per annum. If the open-tank treatment is used, which consists in saturating the poles in alternate hot and cold preservative baths of creosote, the cost per pole is $8.05. These poles last 22 years, which makes the annual cost 61 cents per pole, or 10 cents less per pole than with untreated poles. The use of preservatives is both a saving of expense and a saving of the forests.

Spruce, though at present forming only 0.7 per cent. of the total (5,524 poles being used in 1909) should receive attention.

It is a tree which grows to useful pole size in 60 to 100 years, is cheap, light and easily handled. The reproduction of spruce is excellent. It occurs naturally over large areas in Canada, and, under present conditions of logging, is reproducing rapidly. It is adapted to many kinds of soil and the species is quickly propagated by seed. Untreated, the wood is not durable, but if treated it will last as long as the naturally durable and more expensive species used at present.

Preservative treatments will be of no particular benefit to the lodgepole pine of the West, used chiefly for mining timbers and props. This species is of suitable pole size and occurs extensively on the mountain slopes of Alberta and British Columbia. As an untreated pole, it decays quickly in contact with the soil, lasting about five years. The tree grows tall and straight with very little taper and makes a well-shaped pole. Large quantities of this timber have been killed by fire. The dead trees are now standing thoroughly seasoned and in excellent condition for effective treatment. The sapwood is about an inch thick and is easily impregnated.

It would cost $1.40 per pole to treat by the tank method 35-foot poles of this species. Such a treatment would increase the life of the poles to 20 years, an increase of 300 per cent. over their present life.

The adoption of the preservative treatment of poles would result in a great saving to the pole-users of the prairie provinces. Cedar from Eastern Canada is now used almost exclusively for poles in the prairies, and because of the long freight haul is very expensive. Close to the pole-lines of Western Canada there are large quantities of lodgepine and spruce. Poles of these species may be treated and set for less cost than untreated cedar poles and will give greater service than untreated cedar poles. This is an opportunity for economy which should not be overlooked by companies erecting pole-lines.

Metallurgical Comment

T. R. LOUDON, B.A. Sc.

Correspondence and Discussion Invited

FURNACE ELECTRODES PRACTICALLY CONSIDERED.*

By R. Turnbull.

A number of papers have been read at the various meetings of this society during the last two or three years, and articles published in the technical papers, on electrode losses, but, so far as I am aware, the practical end of the electrode question has never been taken up by any one of our members except in a very superficial manner.

It therefore occurred to me that as electric furnace practice is only confined to a very small percentage of the members of this society, and as there must be quite a number who have never encountered electrode troubles, and who may not understand what benefit the society is getting from the above mentioned discussion on electrode losses, that for these reasons a practical paper written on the subject of electrodes by one who has been in the business for a number of years might prove of some benefit to the members as a whole.

Before going into the history of the electrode, let us first see what relation is has to the electric furnace. Putting it in its simplest form, the electrode is to the electric furnace what the steam pipe is to the steam engine. In the latter case the steam or source of energy is carried to the engine in the pipe at a certain pressure, represented by pounds per square inch and the volume of steam by the number of cubic feet. To get more power, should the volume be increased the pipe must be made larger in diameter, in order to avoid frictional losses, etc. The same result could be attained, within a certain limit, by increasing the pressure and allowing the volume to remain the same. In the case of the electrode, the pressure and volume of the steam are replaced by volts and amperes; an electrode, if large enough, will carry to the furnace a certain number of amperes with very little loss in volts, but as the amperes increase, the section of the electrode must also be increased, otherwise the loss in volts by resistance in the electrode will become serious and considerably decrease the output of the furnace. As in the case of the steam pipe, the pressure in volts might be increased in order to get more power into the furnace, but electric furnace operation is generally controlled by the voltage, and a variation from the usual number of volts would upset the good operation of the furnace.

Now let us examine what an electrode is composed of, and what constitutes a good and bad electrode.[1] The mixture used in the manufacture of the ordinary electrode is anything but a complicated one, being simply some kind of carbon mixed with certain percentages of pitch and tar. This, after being well mixed together, is moulded in some special apparatus to the desired form, and then baked in a furnace in a non-oxidizing atmosphere. This looks simple, and when one looks back on the troubles and tribulations experienced by technical men in electric furnace work over quite a number of years, due mainly to bad electrodes, it seems strange that the secret of making electrodes which would not break was not discovered long ago. But good electrodes were made from the very beginning, and it is quite possible that amongst the first batch of electrodes made some were equal in quality to the best electrodes made at the present day. This was where the great difficulty confronting the manufacturer lay, in his ability to, unintentionally, turn out a first-class electrode and a thoroughly bad one at the same time and under exactly the same conditions. Electrodes made at the same time, under the same conditions, and baked in the same furnace, have shown in actual service as many different characteristics in quality as could well be imagined, some giving excellent service whilst others simply went to pieces after being in operation for a few minutes.

As the electrode is to the electric furnace what the gasoline motor is to the aeroplane, one can well imagine what a bad electrode meant to the operator of the electric furnace; without the efficient gasoline engine the aeroplane would probably be unknown, and the same might be said would be the case of the electric furnace without good electrodes.

In the early stages of electrode manufacture petroleum coke was mostly employed, it being first of all calcined to drive off all volatile matter. This was afterwards replaced by retort carbon, a kind of coke which is deposited in the retorts in gas works, and which is nearly pure carbon. Better results were obtained by the use of retort carbon than with petroleum coke, and it was considered for a time the only material with which a reasonably good electrode could be turned out. I have not sufficient data to enable me to say when and where the first large electrodes were made, but I should not be far wrong in saying that they were first made by Dr. P. Héroult at his works in Froges, France, some fifteen years ago; at that time he made them as large as 16 inches (40 cm.) square and 6 feet (1.8 m.) long. Some of these first electrodes manufactured by him were very good, and some very bad, and little if any reliable data could be collected from his work. I should like to say here, however, Dr. Héroult has not abandoned the field, he having established works in Niagara Falls, N.Y., where excellent electrodes are now being turned out, and although the process used is different in some respects from his original one, he is still working along the same lines. His original process is still being used with good results at at Welland, Ontario, by Electro-Metals, Limited.

Now, what was the reason of so many failures to turn out a good article in the early days, and why do nearly all electrode manufacturers, even those who have been but a short time in the business, turn out to-day a fairly satisfactory article? I think I am not far wrong in saying that the main cause of failure was in the use of the wrong carbon material. Petroleum coke did not work well, and electrodes made from it crumbled to pieces in the furnaces. Retort carbon made a better electrode, but as this commodity was collected from gas works all over the world, a homogeneous article could not be counted upon, and this made its use dangerous to the manufacturer, so far as reliability was concerned. It was only when anthracite coal came into use that real progress was made, and the best kind of electrodes in use to-day are made from this material. Hardmuth, of Venisseux, France, was, if I am not mistaken, the first to use anthracite coal on a large scale, and for some time his electrodes were the best in the market. He was quickly followed by the German makers.

* Read before the American Electro-Chemical Society on April 19th 1912.

[1] There are two classes of electrodes, the amorphous carbon and the graphite; it is the former to which I wish to draw attention, as graphite is prohibitive for ordinary furnace practice, owing to its high cost.

the Plania Werke and Siemens. We are indebted to-day to the Plania Werke for the moulded screw, which enables electrodes to be joined together, thus doing away with the stub and machining of the electrode and the trouble of changing electrodes in the furnace. This screwed electrode applies mainly to furnaces for the manufacture and refining of steel. At the present time nearly all manufacturers are using anthracite coal as the carbon base, and while electrodes made by some manufacturers are superior to those made by others, this is mainly due to the different methods of moulding the electrodes and preparing the coal employed.

So much progress has been made in this industry in the last two or three years that perfectly satisfactory electrodes up to 24 inches (60 cm.) in diameter and 7 feet (2.1 m.) long are now being made, whilst only a few years ago nothing over 12 inches (30 cm.) square and five feet (1.5 m.) long was satisfactory. No doubt still larger electrodes can and will be built, as electric furnaces are still growing in size, and the time is not far distant when steel furnaces of 30 tons' capacity, and operating with electrodes three feet (0.9 m.) in diameter, will be as common as are our small 5-ton furnaces of to-day.

Before closing this paper, I would like to give a few hints as to the best manner of employing an electrode in order to ensure the best service and avoid the losses of which we have heard so much. Carbon, unlike metals, is a better conductor hot than cold, and the hotter it is, the better conductor it becomes. Carbon, however, even at a very high heat, is still a poor conductor, and it is impossible in actual practice to avoid some loss in the electrode itself. In all conductors, the longer the conductor, the greater the loss, but this loss can be lessened by increasing the size of the conductor. This same rule applies to electrodes, and in order to avoid all losses to the greatest extent possible the current should enter the electrode at a point as near as possible to the point where it will leave it. It is quite common practice to connect the metallic conductor to the head of the electrode, but this is a grave mistake, as the loss in volts in a long electrode will be from 4 to 6, depending on the current density employed, and in a furnace where the operating voltage is 50 volts, this loss would be equal to from 8 to 12 per cent. of the total energy consumed. Electrodes should be held in the same manner as one would hold a bar vertically in the hand, so that they can be taken at any point on their length, and in smelting furnaces the holder giving contact to the electrode should not be at any time more than 1 foot (30 cm.) above the charge. As the electrode wears away it is slipped through the holder, and the process goes on until it is finally taken by the head, but at no time should the part of the electrode carrying the current project more than 2 to 6 inches (5 to 15 cm.) from the holder itself. The losses, both of heat and energy, can be decreased by increasing the size of the electrode, but this can be carried too far. The writer would recommend a current density of from 30 to 35 amperes to the square inch of section (5 to 6 per sq. cm.) in order to keep the electrode as cool as possible and thereby prevent side oxidation and heat losses. With too large an electrode, quite a good percentage of the total energy supplied to the furnace would be required to keep the electrode warm.

An important point, the value of which is sometimes overlooked when considering the size of electrodes, is that it is often advisable to use electrodes of greater cross-section than electrical necessity demands, but for a totally different reason. In some processes, for instance, the electrode when working is surrounded to a certain depth by charge mixture. At the surface of such charge mixture, and therefore at some distance from the working end of the electrode, inflammable gases are given off, and these burning in air tend to attack and consume the electrode. Thus there is a tendency to reduce cross-section at this point with consequent increased current density, followed by rise of temperature, which further aggravates the condition described. It is, therefore, wise, for convenience sake, to use a larger cross-section so that the burning away does not result in eating the electrode through, letting a large piece of electrode into the charge and disturbing conditions generally This is one of the exigencies imposed by practice.

FERRO-SILICON, FERRO-CHROME AND FERRO-PHOSPHORUS.

Ferro-silicon, ferro-chrome, ferro-phosphorus, etc., have been made in electric furnaces at Buckingham, Que., by the Electric Reduction Company, Limited. The furnaces were not in operation during 1910. Ferro-silicon has also been made in electric furnaces at Sault Ste. Marie, and at Welland, Ont. The electric furnaces operated by the Electric Metals Company were in operation during 1910. These furnaces, constructed some three years ago, consist of four furnaces of from 1,000 to 1,500 horse-power each, the daily production being from 5 to 8 tons.

The imports of ferro-silicon, manganese, etc., during 1910 were 18,900 tons valued at $464,741, or an average of $24.59 per ton. The imports during 1910 were 17,699 tons valued at $411,536, an average of $23.25 per ton.

Returns of steel production received direct from the producers showed a total production of ingots and castings for 1910 of 822,284 tons, as compared with 754,719 tons in 1909, and 588,763 tons in 1908. In 1910 the production of open-hearth ingots was reported as 580,932 tons, Bessemer ingots 222,668 tons, direct open-hearth castings 18,085 tons, and other steels 599 tons; compared with 1909 there was an increase in total production of 67,565 tons, or nearly 9 per cent.

Statistics showing the quantities of the principal materials used in steel furnaces have been obtained for the first time for the year 1910, and it may be of interest to refer to these here. The total quantity of pig iron used in steel furnaces during 1910 was 690,913 tons: of which 601,219 tons were produced by firms reporting, and 89,694 tons purchased. The quantity of ferro-alloys used was 8,143 tons purchased. Scrap, etc., was used to the extent of 211,453 tons, being 140,913 tons produced by the firms reporting, and 70,540 tons purchased. Ores used included 1,317 tons of manganese ore and 39,332 tons of iron ore, while 144,110 tons of limestone or dolomite flux were used 7,461 tons of fluorspar. In Ontario a little over 600 million cubic feet of natural gas were used, while in Nova Scotia, coke oven gas was used at Sydney, of which a record of quantity is not obtained.

Complete statistics of the production of rolled products and of manufactured steel have not been received. Returns from seven of the largest producers show a production of blooms, billets, slabs, etc., of 628,100 tons, of which 580,533 tons were used by the producer for further manufacture, and 47,567 tons sold to other rolling mills.

The production of rails was 399,762 tons, of rods 88,456 tons, of bars 125,778 tons, of other rolled products 31,516 tons. The production of steel rails in 1909 was returned as 377,642 tons, and in 1908, 300,935 tons.

CHEMISTRY IN SWEDEN.

Chemistry has played an important part in the industrial history of Sweden. No less than twenty of the known chemical elements have been discovered by Swedes.

EXPERIMENTS ON HEAT INSULATION.*

By F. A. J. FitzGerald.

At the twentieth general meeting of this society a paper[1] was presented describing an electric furnace experiment in which it was found that the heat losses were so great that the furnace was not commercially practicable. It was also observed that by placing a layer of special heat insulating bricks wherever practicable on the outer walls of the furnace the heat losses were much diminished.

The very serious consequences of not attending properly to heat insulation led to an attempt to study the subject of heat losses, and the following paper describes some of the preliminary experiments.

Energy which should be usefully employed in the electric furnace is lost in various ways: Current leakage, generation of heat in the cables and other means for conducting the current into the furnace, conduction, convection and radiation of heat by the furnace walls, etc. In many furnaces there can be little doubt that the most serious loss of energy is that due to the escape of heat through the walls.

In the study of this subject we have no data which enables us to make calculations of the heat losses which will occur with different materials and under various conditions. No doubt there have been careful and valuable investigations made on the heat conductivity of materials and some experiments on the emissivity of hot bodies. Little information is available as regards convection. When such data as we have on these various causes of heat loss are examined and an attempt made to calculate probable losses the results are usually most unsatisfactory. On the other hand it is still more unsatisfactory to construct electric furnaces and find that they are commercially impracticable because the heat loss through the walls is such a large percentage of the total heat generated in the furnace.

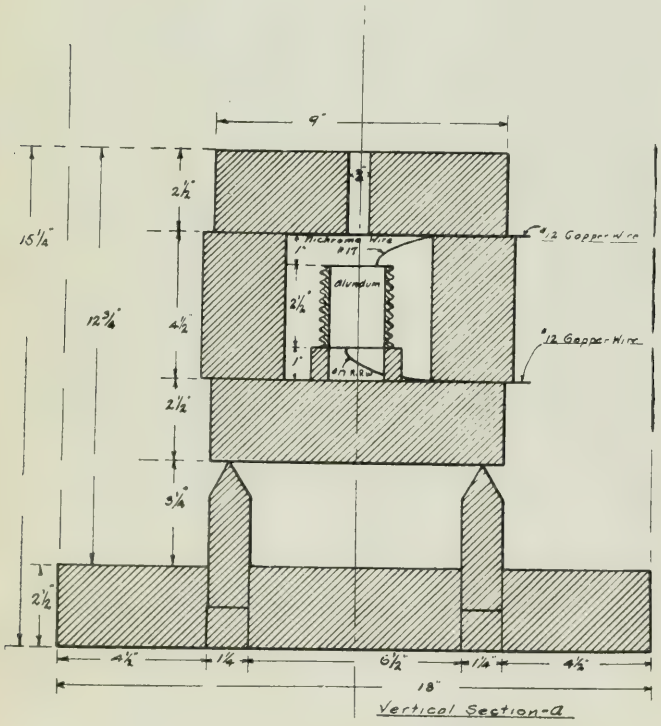

Fig. 1.

The ideal method of studying the subject would be to make the necessary experiments to determine the heat conductivity of the various materials to be used in constructing the walls of furnaces, to make measurements of the emissivity of the heated walls and so forth. But when the plans for such an investigation are made it is soon seen that much time and expense is involved. Under these circumstances it was thought to be more immediately useful to determine by comparatively simple experiments what materials would give the minimum loss of heat. By such work a great many materials could be immediately rejected and those which gave good results would be more fully investigated.

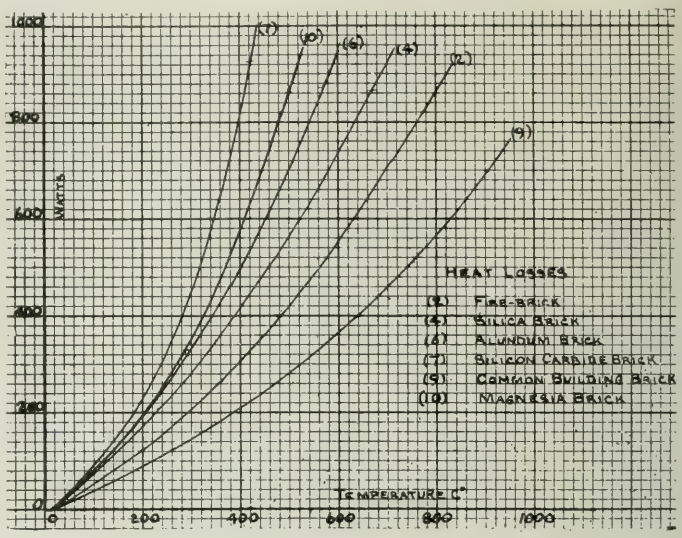

Fig. 2.

The apparatus used in the experiments is shown in Fig. 1. The furnace is constructed of the bricks under investigation and is heated by means of a resistor of "Nichrome" wire through which the current is passed. The resistor is connected to the source of current through a rheostat so that the rate of generation of energy in the resistor can be regulated, and means are provided for accurately measuring this rate. The method of making a test is to regulate the current so that a definite temperature is reached in the furnace and then to continue heating until the temperature becomes perfectly constant. As a rule a single determination takes several hours and the temperature is not considered constant until the readings of the pyrometer show no variation for at least two hours. When the temperature is constant the rate of generation of energy in the resistor is determined and this gives the rate at which heat is escaping through the furnace walls, neglecting what escapes by conduction through the leads going to the resistor and through the wires of the pyrometer thermo-couple. In nearly all cases four determinations at temperatures ranging from 200° to 900° were made for each of the materials tested.

From the data obtained as described above, curves were plotted in which the abscissas are temperatures and the ordinates watts.

In Fig. 2 are shown the curves obtained with several different bricks.

No. 2 is a fire brick of moderately good quality, that is to say, it is not of any special make. It was the brick used in constructing the furnace referred to in the paper mentioned above.[2] The maximum temperature reached in the brick testing furnace was 800°.

---

* Read before the Am. Electro-Chem. Soc., April 18, 1912.

[1] "Note on an Unsuccessful Furnace Experiment," F. A. J. FitzGerald. Transactions 20, 89 (1911).

[2] Ibid.

No. 4 is the curve for a silica brick. It is interesting to note that in the paper already referred to it was said:

"It was recognized that silica brick are better heat insulators than fire brick, as may be seen from Wologdine's determinations[3] which show that the heat conductivity of silica is 0.0020 and of fire brick 0.0042."[4]

It appears, however, that in spite of its low heat conductivity this particular silica brick is not a satisfactory insulator. The maximum temperature reached with the silica brick was 670°. The heat loss here was 36 per cent. greater than with the fire brick. It is not very safe to theorize as to the cause of this phenomenon, but it looks as though the radiation from the surface of the silica brick is very much greater than from the ordinary fire brick. The vast differences due to the nature of the radiating surface is not so surprising if a familiar household phenomenon is considered, viz., the great difference in the rate of cooling of the common black iron kettle and the polished silver tea pot.

No. 6 was obtained from an alundum brick, one of the highly refractory ones made by the Norton Company. The transmission of heat was so rapid with this brick that the maximum temperature obtained in the furnace was only 570°. This illustrates well the value of such alundum refractories as crucibles, muffles, etc., where it is desirable to have as efficient transmission of heat as possible.

No. 7 is the curve for a brick made of silicon carbide. The brick is pure silicon carbide, that is, no bond is used in making it. The transmission of heat is extremely good with this brick so that the maximum temperature reached in the furnace was only 420°. Comparing this brick with the fire brick (2) when the temperature in the furnace was the same (420°) it is seen that the rate of escape of energy is 920 watts and 300 watts respectively, or more than three times as great in the case of the silicon carbide brick.

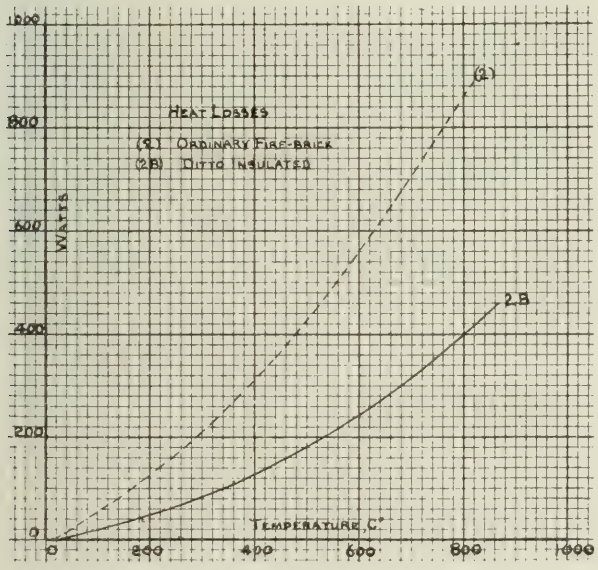

Fig. 3.

Curve No. 9 is that for an ordinary red building brick of the cheapest kind. It is seen to be the best insulator of any of this lot, the heat losses being as much as 34 per cent. less than those for the fire brick (2) at a furnace temperature of 800°.

Curve No. 10 shows the results obtained with a magnesia brick. This was of a standard kind made of brown magnesia and not the Grecian magnesia variety.

[3] Electrochemical & Metallurgical Industry, Vol. VI. (1909), page 383.

[4] These Transactions, Vol. 20, 89 (1911).

In Fig. 3 are shown the results obtained, first with the ordinary fire brick (2) and then after covering the whole furnace built of this brick with a 25 mm. (1 inch) thickness of a special heat insulating material kindly supplied by a well-known manufacturer. It will be observed that this material reduced the heat losses by more than 50 per cent.

In Fig. 4 is a comparison of the heat losses obtained with the ordinary fire brick (2) and a brick specially constructed for heat insulation. Here it will be observed that in the case of the special insulating brick the heat losses are reduced 68 per cent.

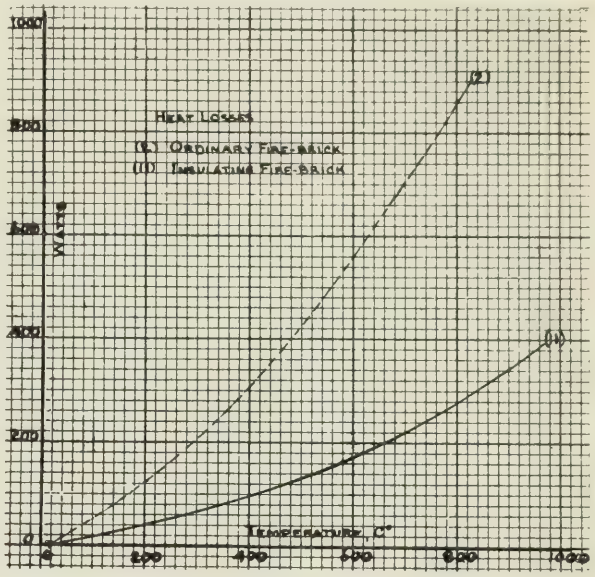

Fig. 4.

The first object of this work is to make a study in the quickest way possible of the heat insulating properties of various kinds of brick used in building furnaces and get some notion of the amount of heat lost with such materials. The ultimate object in view is the production of a heat insulating article, the cost of which will be less than that of the watt-hours uselessly dissipated through furnace walls.

TERMINAL BRAKE TESTING.*

By F. B. Farmer.

As we seek efficient train brakes and as the standard set by law is based on the train, it is obvious that terminal brake tests of trains must be made. Stated differently, the requirements can not be met by confining inspecting, testing and repairing to shops and repair tracks. Consideration of overtime and the sixteen-hour law, as well as expeditious train movement demand the minimum lapse of time between that for which the crew is called and the time the train departs. Hence, a train prepared for departure should require no more brake work after the engine is coupled than, at the most, stopping a few leaks in hose couplings and making the formal test. But often there are greater delays due to making other repairs, or the train proceeds with less efficient brakes than it should have. To avoid this, the repairs required must be determined with arriving trains. The incoming engineer should add to the reduction required for stopping enough to fully apply the brakes, and the brake-

* Abstract of a paper read at the December meeting of the Western Railway Club, Chicago.

man should await his advice that this has been done before cutting off the engine. Car inspectors should be present to make an immediate examination and to bad order all defective brakes. Such repairs as ordinary brake pipe leaks, defective hose and wrong piston travel, which require little time, should be made, but cars requiring heavy brake repairs should be marked for the repair tracks.

Here is where judgment must be exercised, as perishable or other very important loads, as well as empties needed at once for such lading, must not be delayed. Neither should other less important cars be held in numbers far greater than the local force can repair in a day if such force is as great as the regular amount of work, including such repairs, would keep busy. The car foreman and the yard master should consult to adjust this, but when the former removes bad order marks without repairs having been made, he should fill out and apply an air brake defect card to better insure prompt repairs at the earliest practicable date. However, it does not follow that the repairing of defective brakes cannot be done without delay to cars which should go forward promptly. The Minneapolis, St. Paul & Sault Ste. Marie has largely solved this problem at an important terminal yard by assigning a short track in the yard for air brake repairs to such cars. With a few men and the necessary repair materials, such cars are often ready for the first train out, are never actually delayed, and few are allowed to go forward without repairs. This is but one detail of a very comprehensive scheme of improvement in freight brake maintenance effected by this road.

As one repair point on a large system cannot maintain all freight car brakes, it is obvious that each terminal should do its share, but this does not mean that other than the outgoing test should be made on through trains at the points with small facilities. A brake well repaired will go for a long period without becoming defective, but the too common failure to do so is due to inadequate repairs. To reduce the cost of brake cleaning by leaving cylinders and auxiliary reservoirs loose on the car is to insure leaky pipes. The same result follows if the brake pipe and retaining valve pipe are not well secured. That most serious fault, brake cylinder leakage, will develop sooner than it should, sometimes immediately after the cleaning, unless a suitable lubricant is employed and packing leathers are replaced when a good inspection and a careful test would show that they should be. The practice often followed of cleaning and testing triple valves on the car cannot insure good work. Neither is it common practice to test hose with soap suds while under maximum pressure and remove those found porous, or to examine the retaining valve weight and clean the case and small vent port. Until these and other details are given better attention in shops and on repair tracks, it will not be possible to effect the economy in time and money in terminal brake testing and the consequent repairs that will otherwise follow.

The M. C. B. requirement that cars in interchange must have retaining valves should imply the maintenance of this part and its pipe by the owning road. It is not sufficient to say that the mountain road may make needed repairs at the owners' expense, as this means undue delay to traffic. However, inspections show that the average efficiency of brakes is otherwise much lower on the cars of level grade roads, a condition for which there is no warrant as that for the average mountain grade road is enough below 100 per cent. efficiency to justify making it the minimum.

That the regular terminal test of freight train brakes misses many of the defects which nullify the object sought in attaching air brakes, is conclusively demonstrated by the following: Within a few months competent parties made a test on several freight trains at the summit of a mountain grade, following a similar test by regular inspectors at the preceding division terminal, and out of which trains bound down this grade were supposed to leave with 100 per cent. efficient brakes, based on such test. The tests consisted of charging to 70 lbs., making a service reduction of 15 lbs.

Per Cent Good Brakes by Test.		Tons per Good Brake by Test.		Cars per Train.
Standing.	Thermal.	Standing.	Thermal.	
97.7	68.8	42.6	59.5	61
91.0	75.0	45.0	54.6	56
100.0	60.0	40.7	67.6	58
98.1	53.7	42.5	77.6	54
98.1	52.8	43.8	81.5	53
96.4	53.5	41.7	75.0	56
88.9	67.2	46.2	61.2	55

and rapidly examining for any brakes failing to apply or leaking off and incorrect piston travel. To show conclusively the oversights of the ordinary terminal brake test the infallible thermal brake test was made on each train at the foot of the grade. The customary plan was there followed of considering three cars with "warm" wheels equal to one with "normal" wheels; that is with a good brake. In addition to showing the results in percentage, they are given in "tons per good brake," derived by dividing the train tonnage by the number of good brakes.

The first train was a test train and had 2,501 tons. The other six were regular trains and ran from 2,252 to 2,367 tons, averaging 2,286 tons. Each train had a considerable percentage of foreign cars. No tests of or repairs to retaining valves were made.

The big returns from good brakes are mainly concealed, consisting of the more expeditious train movement they make possible and the avoidance of accidents, neither of which can ordinarily be shown in dollars and cents. Their observable expenses, consisting of initial cost, maintenance, flat and cracked wheels and delays to cars and trains for brake testing and repairs, are so readily seen and tabulated as to generally render even more obscure their great but intangible credit account. The pressing need is for a more accurate and practical appreciation of the fact that good brake maintenance is economy and for better directed efforts toward improved brake maintenance with a minimum increase in time and money spent. In this the active cooperation of the yard master and the superintendent will aid greatly. Too often their efforts are directed toward showing why trains cannot be held or switching done for brake work, rather than how to accomplish the desired results with the least delay or additional switching.

THE CITY AND SUBURBS PLANS ACT.

The following is the text of the new Act respecting Surveys and Plans of Land in Certain Cities and Their Suburbs, passed by the Legislature of Ontario:

Where any person is desirous of surveying and subdividing into lots with a view to the registration of a plan of the survey and subdivision, any tract of land lying within or within five miles of a city, having a population of not less than 50,000, he shall submit a plan of the proposed survey and subdivision to the Ontario Railway and Municipal Board for its approval.

The Board shall have authority before approving of the proposed plan to require such changes to be made in it as the Board may deem proper as to:—

(a) The number and width of the roads or streets;

(b) The direction in which the roads and streets are to run and their location; and

(c) The size and form of the lots.

Nothing in clause (a) shall authorize the laying out of any road or street, less than 66 feet in width.

In determining as to the suitability of the proposed plan, or as to the desirability of any change in it, the Board where the land lies within the city shall have regard to making the subdivision and roads and streets and their location and width, and the direction in which they are to run, conform as far as practicable with any general plan which has been adopted or approved by the council of the city in accordance with which it is contemplated that the city and suburbs shall be laid out or the re-arrangement of the streets and thoroughfares shall be effected, and where the land is situate without the limits of the city, the Board shall have regard to

(a) The proximity of the land to the city;

(b) The probability of the limits of the city being extended so as to include it;

(c) The securing of driveways and adequate thoroughfares connecting the city and the outlying districts;

(d) Making the subdivision and the roads and streets and their location, and width, and the direction in which they are to run, conform as far as practicable with any plan so adopted or approved or if no such plan has been adopted or approved with the plan on which that part of the city which lies nearest to the land is laid out.

No plan of any such land shall be registered unless it has been approved by the Board and a certificate of its approval, signed by the chairman or a member of the Board or the secretary is endorsed on the plan, and no lot laid down on a plan, not so approved shall be sold or conveyed by a description containing any reference to the lot as so laid down or to such plan.

Notice of an application to the Board for its approval of a plan, shall be given to the corporation of the municipality in which the land is situate and to the corporation of the city, and all parties interested shall be entitled to be heard, and maybe represented by counsel at the hearing of the application.

A copy of the plan shall accompany such notice.

Objections to the plan shall be stated in writing and be filed with the secretary of the Board within 21 days after delivery of the notice and plan.

If no objection is made within that period the applicant shall be entitled to have the plan certified as approved, unless the Board of its own motion shall have otherwise directed.

Sittings of the Board shall, if required by the council or municipality objecting to the plan, take place at such time and place in the city nearest to the land, as the Board, by notice to the applicant and to the clerk of the municipality requesting the same, appoints.

ENGINEERING NOTES.

Province of Ontario.—Under the provision of the Public Health Act, the Provincial Government will organize seven health districts. Two of these will be in New Ontario, two in the sparsely settled districts stretching across from Georgian Bay to the Ottawa River, and the remainder so arranged as to produce the best results, having regard to population and natural conditions. This will mean in all fourteen salaried appointments—seven district health officers and seven inspectors, the former to receive a salary of $2,500 per year, the latter $1,000. These districts will be so arranged as not to conflict with the work of the municipal health bodies now working in towns and cities that are not part of counties, and the organization will be made effective as soon as the present officials serve out their terms of office.

Mr. J. B. Shelton, car foreman of the Grand Trunk Pacific shops at Transcona, Man., is building a new truck and sleeping-car for the use of employees when called to wrecks. The car will be a model of its kind, and will materially add to the comfort of the men.

PERSONAL.

Mr. F. B. Connery has resigned from his position as superintendent of overhead construction work with the Toronto Hydro-Electric Commission and has accepted a similar position with the Toronto Power Company.

Mr. Jackson Clark, of Wellington, Ont., has received the appointment of assistant district provincial surveyor and will be located at North Battleford, Saskatchewan. Mr. Clark graduated from the School of Practical Science this year.

Mr. Alan Mair Jackson, who has just passed his final O.L.S. examination, has been appointed county engineer for Haldimand county, with headquarters at Dunnville, Ont. Mr. Jackson is an associate member of the Institute of Mining and Metallurgy.

OBITUARY.

Charles Robert Boucher, one of the most widely known railroad engineers in Canada, died at Sault Ste. Marie, Ont., on April 26th last. Up to the time of his illness he had been engaged in building bridges along the line of the Algoma Central Railway. He was also prominent in the construction of the Temiskaming and Northern Ontario, and had been from coast to coast on both sides of the border in railroad construction. He was buried in New York. He leaves a widow and one son. He was 64 years of age.

BOARD OF GOVERNORS OF THE UNIVERSITY OF TORONTO.

Mr. T. A. Russell and Lieut.-Col. Albert E. Gooderham were appointed by the Provincial Government on April 25th to places on the Board of Governors of the University of Toronto. These gentlemen are to take the places formerly occupied by Hon. W. T. White and Hon. T. W. Crothers. The appointments take effect at once.

NEW PRESIDENT OF AMERICAN ELECTRO-CHEMICAL SOCIETY.

Mr. William Lash Miller, professor of chemistry at the University of Toronto, has been elected president of the American Electro-chemical Society.

To a Canadian this is a signal honor, in view of the fact that he will represent the American Electro-chemical Society at the Congress of Applied Chemistry, which meets in Washington next September on the invitation of the President and Government of the United States.

At the meeting of the Congress, which is held every five years, will be industrial chemists from all over the world. This will be the first time the society has met in America. The last meeting was in Rome.

ANNUAL MEETING SOCIETY OF CHEMICAL INDUSTRY.

The Society of Chemical Industry elected the following officers at the annual meeting held April 25th, Toronto: Chairman, Wallace P. Cohoe; vice-chairman, R. F. Ruttan, W. L. Goodwin and Prof. J. Watson Bain; Executive Committee, H. P. Mills, O. H. Wurster, R. T. Mohan of Hamilton, A. Neighorn, Milton L. Hersey, C. F. Heebner, J. A. De Cew, Prof. W. Lash Miller, G. F. Guttman, N. N. Evans, T. H. Wardleworth, E. G. R. Ardagh.

Mr. O. H. Wurster read a paper on the manufacture of glycerine as a by-product of soap. He showed the various methods used commercially, and which may be used in the future for the refining of the crude glycerine so produced in order that the glycerine may be used in the manufacture of dynamite, and also to produce a chemically pure glycerine for other purposes.

Mr. Anthony McGill, LL.D., of the Inland Revenue Department, Ottawa, presided.

COMING MEETINGS.

CANADIAN INSTITUTE.—198 College Street, Toronto. May 4th—Annual Meeting and Election of Officers. President, J. B. Tyrrell; Secretaay, Mr. J. Patterson.

AMERICAN RAILWAY ASSOCIATION.—May 15th, Semi-Annual meetlng at New York City. Sec'y, W. F. Allen, 75 Church St., New York.

INTERNATIONAL RAILWAY FUEL ASSOCIATION.—May 22nd-25th. Annual Convention at Chicago, Ill. Secy., D. B. Sebastian, La Salle St. station, Chicago.

FOURTH NATIONAL CONFERENCE ON CITY PLANNING.—May 27th-29th. Meeting, Public Library, Boston, Mass. Sec'y, Flavel Shurtleff, 19 Congress Street, Boston, Mass.

AMERICAN WATER WORKS ASSOCIATION.—June 3rd-8th. Annual Convention at Louisville, Ky. Secy., J. M. Diven, 271 River St., Troy, N.Y.

CANADIAN ELECTRICAL ASSOCIATION.—June 19th-21st. Annual meeting at Ottawa, Ont. Sec'y, T. S. Young, 220 King St. West, Toronto, Ont.

SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION.—June 26th-28th. Annual meeting at Boston, Mass. Sec'y, H. H. Norris, Cornell University, Ithica, N.Y.

ONTARIO MUNICIPAL ASSOCIATION —Annual convention will be held in the City Hall, Toronto, on June 18th and 19th, 1912. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ont.

CANADIAN PUBLIC HEALTH ASSOCIATION.—Second Annual Meeting to be held in Toronto, Sept. 16, 17 and 18.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE: Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, S. J. Chapleau, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving; Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, C. E. Cartwright; Secretary, W. Alan, Kennedy; Headquarters: McGill University College, Vancouver.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1290.

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydonejack; Meets every first and third Friday of each month, October to April, in University of Manitoba, Winnipeg.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION.—President, Chas. Hopewell, Mayor, Ottawa; Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm. Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, W. Sanford Evans, Mayor of Winnipeg; Hon. Secretary-Treasurer, W. D. Lighthall, K.C., Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, Mayor Mitchell, Calgary.; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALTIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, N. W. Ryerson Niagara Falls; Secretary, T. S. Young, Canadian Electrical News, Toronto.

CANADIAN FORESTRY ASSOCIATION —President, John Hendry, Vancouver. Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewit, General Manager Consumers' Gas Company, Toronto; J. Keillor, Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President, J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, D. McDonald, Manager, Montreal Street Railway; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, Killaly Gamble, 703 Temple Building, Toronto.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, J. E. Ganier, No. 5. Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, F. S. Baker, F.R.I.B.A., Toronto, Ont.; Hon. Secretary, Alcide Chausse, No. 5. Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman; Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, J. P. McRae; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Wm Pierce, Calgary; Secretary-Treasurer, John T. Hall, Brandon, Man.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, 115 Phœnix Block, Winnipeg, Man. Second Monday, except June, July and August, at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc.
Printed forms for the purpose will be furnished upon application.

PLANS AND SPECIFICATIONS ON FILE.

The following Plans (P.) and Specifications (S.) are on file for reference only unless otherwise noted at the office of The Canadian Engineer, 62 Church Street, Toronto:—

Bids close		Noted in issue of
4-30	Tunnel sewer, Edmonton, Alta. .....(S.)	4-4
4-30	Trunk sewer, Edmonton, Alta. .....(S.)	4-11
4-30	Subway, Moose Jaw, Sask. .....(P. & S.)	4-18
5-10	One diesel oil engine, Vernon, B.C. .....(S.)	4-25
5-15	Reinforced arch bridge, Guelph, Ont...(P. & S.)	5-2
5-29	—Water works, sewerage and electric light systems, Melfort, Sask. .....(P. & S.)	5-2

(Saskatoon plans and specifications are on file at The Canadian Engineer Office, 820 Union Bank Building, Winnipeg).

(Melfort plans and specifications are also on file at The Canadian Engineer Offices, 820 Union Bank Building, Winnipeg, and B33, Board of Trade Building, Montreal).

TENDERS PENDING.

In Addition to Those in this Issue.

Further information may be had from the issues of The Canadian Engineer referred to.

TENDERS.

Arkona, Ont.—Tenders for the erection of the Arkona Baptist Church, plans and specifications of which may be seen by applying to W. J. George, Arkona, will be received by the Secretary, R. Crawford, up to May 10th, 1912.

Cobourg, Ont.—Tenders will be received till the 14th day of May, 1912, for the construction of sewage disposal works for the House of Refuge, Cobourg. Specifications, etc., at the office of the Engineer, T. Aird Murray, 303 Lumsden Building, Toronto, or at the Town Hall, Cobourg. (See advt. in Canadian Engineer).

Guelph, Ont.—Whole or separate tenders addressed to Prof. W. H. Day, O. A. College, will be received up to noon of May 8th, 1912, for the several trades in connection with the erection of a Masonic Temple, Guelph. Plans and specifications may be seen at the office of W. A. Mahoney, Architect, 20 Douglas St.

Grandview, Man.—Tenders for the construction during 1912 of about 30,000 feet of granolithic sidewalk in the town of Grandview, Man., will be received by Wm. Dickie, Secretary-Treasurer, Grandview.

Guelph, Ont.—Tenders for the construction of a reinforced arch bridge and viaduct for foot traffic on Heffernan Street, over the C.P. Railway and the River Speed, having a total length of about 520 feet. J. Hutcheon, city engineer. (See advt. in Canadian Engineer.)

Hamilton, Ont.—Tenders will be received up to Thursday, May 30th, 1912, for supplying the corporation of the city of Hamilton with flanged special castings for Beach Pumping Station, 3 Venturi meters, 2 travelling cranes, and water tower. Specifications at the office of the City Engineer. S. H. Kent, City Clerk. (See advt. in Canadian Engineer).

Hamilton, Ont.—Tenders will be received by Geo. H. Lees, Mayor, up to May 9th, 1912, for the several works required in the erection of a public comfort station under Hughson Street roadway. Plans, etc., at the office of the architect, A. W. Peene, No. 2 King Street West, 2nd floor, Hamilton. S. H. Kent, City Clerk, Hamilton.

Kamloops, B.C.—Tenders are invited for the supply of all materials and labor required for the completion of a new High School at Kamloops, B.C. Plans and specifications may be seen at the office of John Parlett, architect, Freemont Block, Victoria Street, Kamloops.

London, Ont.—Tenders for fifteen bridges to be erected in London Township will be received by Mary Grant, clerk, 110 Dundas Street, London, until noon of May 4th, 1912. Plans and specifications at the County Engineer's office, County Buildings, city.

Melfort, Sask.—Tenders will be received until May 29th, 1912, for water works, sewerage and electric light systems for the town of Melfort. J. E. Durin, secretary-treasurer, Melfort, Sask. Messrs. McArthur, Murphy and Underwood, engineers. Bottomley Block, Saskatoon, Sask. (See advt. in Canadian Engineer.)

Province of New Brunswick.—The Department of Public Works, Fredericton, will receive tenders for the rebuilding of Lane's Creek arch bridge culvert at Upper Woodstock, Carleton County. The tenders are to be in by May 20th next.

North Battleford, Sask.—Tenders will be received by the Secretary-Treasurer until 8 p.m., on the dates specified against the respective works, for the following, viz.:—

Contract H, furnishing and erecting boiler, May 15th.

Contract J, furnishing and erecting 750 horse-power steam engine and accessories, May 15th.

Contract K, furnishing and erecting 500 k.w. generator and equipment, May 15th.

Plans and specifications may be seen at the office of the engineers, Toronto and Winnipeg, and at the town hall, North Battleford. J. Griese, Esq., Mayor. H. W. Dixon, Secretary-Treasurer. Chipman & Power, Engineers.

Ottawa, Ont.—Tenders for the construction of a Public Building at Wallaceburg, Ont., will be received at the Department of Public Works, Ottawa, up to 4 p.m., on Wednesday, May 13th, 1912. Plans, etc., at the Post Office, London, Ont.; Post Office, Wallaceburg, Ont., and at the office of R. C. Desrochers, Secretary, Department of Public Works, Ottawa.

Ottawa, Ont.—The Department of Trade & Commerce has been advised that the Commonwealth of Australia is inviting tenders for 135,633 tons of steel rails and 9,644 tons of fish plates required for the government railway system. Tenders close on May 29th. Canadian manufacturers will forward offers by mail which leaves San Francisco on May 1st. Rails and fish plates are to be of open hearth steel, and are to be delivered at Fremantle and Port Augusta. The rails are to be 80 pounds to the yard mostly, but a small portion is to be 60 pound rails.

Ottawa, Ont.—Tenders will be received by the secretary, R. C. Desrochers, Dept. of Public Works, until May 13th, 1912, for dredging required at the following places in the province of Ontario: Goderich, Napanee, Picton, Telegraph and Nigger Islands.

Ottawa, Ont.—Tenders will be received by the secretary, R. C. Desrochers, Dept. of Public Works, Ottawa, up to May 15th, 1912, for dredging required at the following places in the province of Ontario: Lanoraie, Woodland, Vercheres, Varennes and Lavaltrie. Specifications, etc., at the office of the Dept. of Public Works, Ottawa.

Owen Sound, Ont.—Tenders for a concrete dam at Inglis Falls will be received up to noon, Monday, May 13th, 1912, at the office of the Wm. Kennedy & Sons, Ltd., Owen Sound, at which place plans and specifications are to be seen.

Owen Sound, Ont.—Tenders will be received up to noon of May 9th, 1912, for all trades required in the erection of a Public Library Building at Owen Sound. Drawings, etc., may be obtained at the Architects, Forster & Clark's office. J. H. Packham, Chairman of the Board.

Regina, Sask. — Tenders will be received by the City Commissioners up to noon of May 5th, 1912, for the construction of two filter beds, one stand-by tank, pipe lines connecting with the various parts of the works. Copies of plans and specifications may be had from J. M. MacKay, chief engineer, trunk sewer works, Regina.

Saskatoon, Sask.—Tenders will be received by the City Commissioners up to noon of Tuesday, June 25th, 1912, for the complete installation (including all buildings) of a 70 ton per 24 hours incinerator plant, and the operation of the same for a period of three months after completion. (See advt. elsewhere in Canadian Engineer.)

Toronto, Ont.—Tenders will be received up to noon, Monday, May 6th, for the dredging of the crib berths at the new Ashbridge's Bay docks. Plans of location, etc., may be obtained at the office of the Toronto Harbor Commissioners, 76 Adelaide Street West. F. S. Spence, Acting Chairman.

Weyburn, Sask.—The Secretary, Weyburn High School, will receive tenders up to Friday, May 10th, for the erection of a Collegiate Institute building. Copies of plans and specifications may be seen at the office of Geo. J. G. Jarrett, architect, Weyburn, and at the Builders' Exchange in Regina and Winnipeg.

Winnipeg, Man.—Tenders, separate, will be received by the Chairman, Board of Control, up to noon of May 15th, 1912, for the manufacture and delivery at the city gravel pit, Bird's Holl, Man., of one electric locomotive with accessories complete, and one electrically-operated shovel with accessories complete. Specifications, etc., may be obtained at the office of the City Light and Power Department, 54 King Street. M. Peterson, Secretary, Board of Control Office, Winnipeg.

CONTRACTS AWARDED.

Battleford, Sask.—The Western Pavers, Limited, Saskatoon, have the contract for laying approximately 150,000 sq. ft. of cement sidewalk, with crossings and curbing.

Brandon, Man.—The work of construction on the two wings of the new asylum will be carried out by Mr. John Clark, who also has the contract for the main building, which will soon be completed. The addition will be the same height as the rest of the new building, and will cost over $100,000.

Fredericton, N.B.—The Fredericton & Grand Lake Coal & Railway Company have signed a contract with Messrs. A. E. Trites & Son for the construction of the Gibson and Minto Railway. The contract calls for the construction of the road between Gibson and Minto, a distance of 31 miles, and also for the construction of the masonry structures of the several bridges on the line. The Dominion Bridge Company of Montreal will have the contract for the superstructures of the bridges. The cost of the railway, including bridges, will be $650,000.

Kenora, Ont.—The contract for the installation of the new electrical unit in the power-house has been awarded to Messrs. Allis-Chalmers-Bullock Company of Montreal. The contract amounts to $25,000.

Lake Quinze, Maple Rapids, Que.—Dam and sluiceways, contractors, Messrs. Morrow and Beatty, of Peterborough, Ontario.

Little Lameque, N.B.—Wharf: Contractor, H. G. Beresford, of St. John, N.B.

Moose Jaw, Sask.—The contract for laying about 96,000 lineal feet of 18-inch steel water pipe has been awarded, one-half to Maurice S. Holmes, Souris, Man., at 90c. per lineal foot complete, and the other half to the Moose Jaw Construction Company, Limited, at 94c. per lineal foot complete. Walter J. Francis and Company, Consulting Engineers.

Moose Jaw, Sask.—The Moose Jaw Construction Company, Limited, have received contract for supplying and erecting a reinforced concrete reservoir of 2,000,000 gallons capacity at a cost of $34,352. Walter J. Francis and Company, Consulting Engineers.

Moose Jaw, Sask.—The contract for supplying and erecting four centrifugal pumps, two motors, wiring, switchboard and accessories, has been awarded to The Canadian Boving Company, Limited, 164 Bay Street, Toronto. Price, $4,075. Walter J. Francis and Company, Consulting Engineers.

Moose Jaw, Sask.—Contracts for supplying and erecting two prime mover equipments, transmission equipment and accessories for headworks pumping station at Caron, have been awarded to the Canadian Fairbanks-Morse Co., Ltd., of Montreal, their price being $8,755.

Moose Jaw, Sask.—Supply of various valves and fittings for waterworks installation: Contractors, Messrs. Drummond, McColl & Co., Montreal, Que., unit prices total amounts to about $8,000.

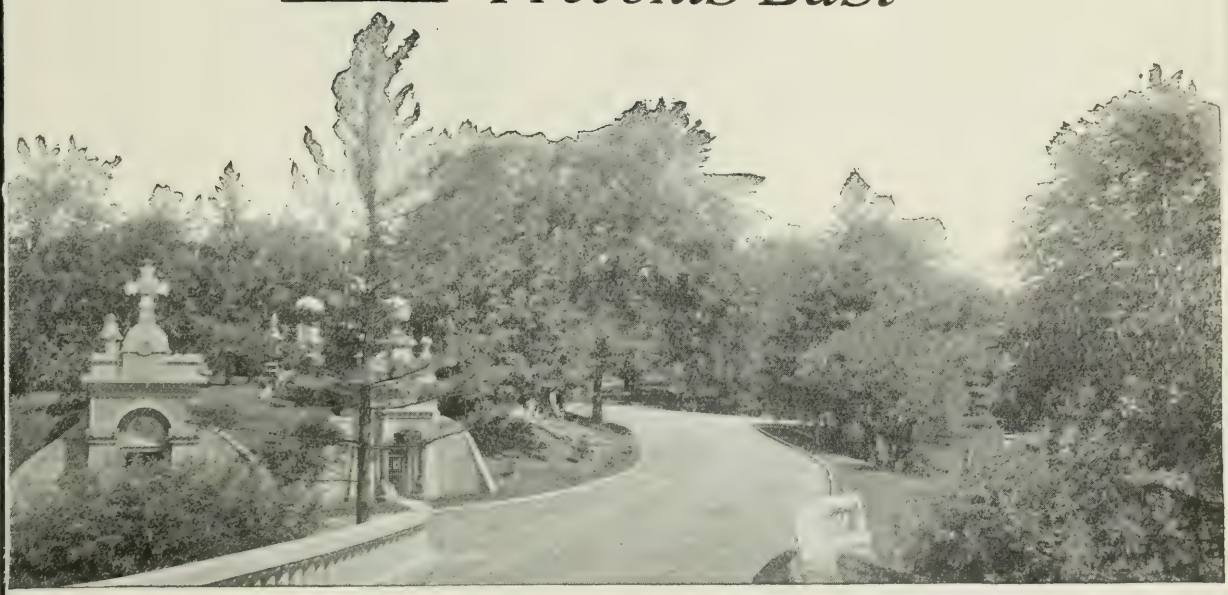
Moose Jaw, Sask.—The contract for supplying and erecting one elevated water tank of 75,000 gallons' capacity, has been awarded to George T. Horton, Washington Heights Station, Chicago, Ill., at a cost of $6,400.

Moose Jaw, Sask.—The following tenders were received for the extensions that are to be made to the King Edward Schools: The Western Building Company, $30,972; Gowan & Potts, $32,950; and Navin Bros., $31,500. The Western Building Company received the contract, which includes heating and all other necessaries.

Moose Jaw, Sask.—Contract for the supply and delivery of sewer pipe and specials f.o.b. cars, Moose Jaw, has been awarded to the Dominion Sewer Pipe Co., Swansea; price, $5,117.85. Other bidders were: The Ontario Sewer Pipe Co., Mimico, $5,500; Messrs. Whitlock & Marlatt, Moose Jaw, $5,555; Saskatchewan Glass & Supply Co., city, $5,659.75; Astrid S. Paving Co., Chicago, $5,677.50; Toronto Pottery Co., $5,865.50.

Tarvia

Preserves Roads
Prevents Dust~



Mount Pleasant Cemetery, Toronto. Roads built with Tarvia X in 1909.

Two Years' Trial in Toronto

THE above roadway in Mount Pleasant Cemetery, Toronto, was built with "Tarvia X" in 1909. The photograph was taken in the fall of 1911 and gives a fair idea of the excellent condition of this road, after two years of travel.

In the background this road has a five per cent. grade and if ordinary macadam had been used the surface would be raveled and worn out long ago. The best demonstration of the success of Tarvia is that the Cemetery authorities, after two years, are going to use a great deal more of it, as the following letter from the Superintendent shows:

February 15th, 1912.

Dear Sirs:

I wish to let you know we will require "Tarvia X" to build about 6500 yds. of road this year about the end of July.

I may say that we are well pleased with our Tarvia roads. The first that were made in 1909 have stood the test of traffic and heavy loads up to 16 tons—the wagon wheels leaving no impression.

Where our roads have a 7% grade we find the Tarvia fills the bill; no washing, no dust, easy to sweep and clean in wet weather.

(Signed) W. H. FOORD, Supt.

Tarvia is a dense, viscid tar product of great adhesive power. When built into the road as a binder, it forms a matrix about the stone, keeps the stone in position and furnishes an element of plasticity which greatly prolongs the life of the macadam under heavy loads or automobile traffic. There are three grades for different types and conditions of roads.

Booklets regarding same free on request.

The Paterson Manufacturing Co., Limited

MONTREAL TORONTO WINNIPEG VANCOUVER

The Carritte-Paterson Manufacturing Co., Limited

ST. JOHN, N.B. HALIFAX, N.S.

North Battleford, Sask.—Messrs. Kilbride, Kilbride & Sutherland, of North Battleford and Calgary, have received the contract for 180,000 sq. ft. of concrete sidewalk. Price, 10-ft. walk, 18c.; 6-ft., 5-ft., and 4-ft. walk, 15c.

Port Arthur, Ont.—The Northern Electric & Manufacturing Co. have been awarded the contract for the installation of a fire alarm system at a cost of $10,343.

Prince Albert, Sask.—The Ambursen Hydraulic Construction Co. of Montreal, has been awarded the contract for the construction work on the proposed Lacolle Falls power scheme. The estimated cost of the whole undertaking totals up to $945,000.

Regina, Sask.—Contracts for trunk sewer pipe have been awarded by the city council as follows:—

1.—Seventh Avenue Trunk Sewer, the Canadian Lock Joint Pipe Company, $41,133.70.

2.—Wascana Valley Trunk Sewer Contract No. 1, the American Sewer Pipe Company, $29,631.04.

3.—Wascana Trunk Sewer Contract No. 2, Messrs. Broley & Dicken, of Fernie, B.C., $20,585.20.

Toronto, Ont.—Dredging of Approach Channel to Ferry Wharves at Hanlan's Point, in Toronto Bay: Contractors, the General Construction & Dredging Co., Ltd., of Toronto.

Upper Salmon River, N.B.—Pier: Contractors, Warren Downey and Oscar Downey, of Curryville, N.B.

Victoria, B.C.—The British-American Construction Company have been awarded contracts for the construction of the piers, landing stage, building platform and launching ways in connection with the construction of the G.T.P. drydock at Prince Rupert.

Victoria, B.C.—The contract for the work on the new High School on the site at Fernwood Road, has been awarded to Messrs. Dinsdale & Malcolm. The building is to cost about $329,000.

Winnipeg, Man.—The Burridge-Cooper Company, Limited, of Winnipeg, have the contract for supplying a 50-h.p. gasoline traction engine, delivered f.o.b. city yards at $3,350.

Winnipeg, Man.—Supply of ten double end asphalt wagons, to be delivered f.o.b. cars, city yards; contractors, Messrs. Burridge-Cooper Co., Ltd., Winnipeg; cost, $3,440.

Winnipeg, Man.—Engineer of Construction, J. W. Astley, Winnipeg, has the contract for the erection of a machine shop at city yards, Ross Avenue and Tecumseh Street, at a cost of $16,568.

Winnipeg, Man.—The firm of Barrett & McQueen, contractors, were awarded the contract by the C.P.R. for the erection of a million-bushel transfer elevator in the company's new yards in North Transcona.

RAILWAYS—STEAM AND ELECTRIC.

Calgary, Alta.—A report states that within a month or two work will be started on the building of a railway to the property of the Alberta and Canada Iron Syndicates, 25 miles west of the town of Okotoks, and when the railway is completed, a great smelter and a 400 ton stamp mill will be erected and iron will be mined. The whole project will involve the expenditure of around $5,000,000. P. Burns is behind the venture.

Province of British Columbia.—Messrs. Mackenzie and Mann have purchased the Butte Inlet Railway Charter in this province. It is reported that they will construct about twenty miles of the line during the coming season.

Eastern Ontario.—The Canadian Pacific Railway have recently installed a new block signal system on their lines between Hull and Ottawa. According to the system a train cannot leave Hull or Ottawa before the conductor has obtained a staff which is locked and unlocked by electrical means. Only by deliberately ignoring the system could a collision of two trains occur between Hull and Ottawa.

Province of New Brunswick.—Contracts are being closed for the construction of Gibson and Minto Railway during the season now opening.

Sir Thomas Tait, as president of the Fredericton and Grand Lake Coal and Railway Company, is signing the contract with the Provincial Government, and the work has been offered to Messrs. A. E. Trites & Son, and will be, it is expected, accepted by them.

Northern Ontario.—The T. & N. O. Commissioners have placed an order for a gas-electric car according to a recent report.

Welland, Ont.—A deputation of farmers, fruit-growers and business men from Pelham and Font Hill were promised consideration of their request for line extension from the management of Niagara, St. Catharines and Toronto Electric Railway.

Western Canada.—Revision of existing grades and surveys for double tracking the Canadian Pacific main line between Vancouver and Calgary, a distance of over 600 miles, are now under way. The work is in charge of F. F. Busteed, former general superintendent of the British Columbia division, who has established headquarters at Kamloops, B.C.

LIGHT, HEAT AND POWER.

Prince Albert, Sask.—Mr. J. R. Heckle, representing the Ambursen Hydraulic Construction Company, has made a proposition to the municipal council of this city regarding the construction of a dam and headworks for the Lacolle Falls power scheme.

Province of Quebec.—A notice has been sent out from the department dealing with the provincial water powers to the effect that the proposed auction of water powers in this province arranged to be held on May 14th next has been postponed until June 26th by order of the Minister of Lands and Forests.

Winnipeg, Man.—Considerable activity will soon be witnessed in the matter of line construction in and around this city owing to the department having charge of the civic light and power calling tenders for 2,000 wooden poles.

GARBAGE, SEWAGE AND WATER.

Cartierville, P.Q.—A sterilization system depending on hypochlorite of calcium has been installed in this municipality under the supervision of Engineer Meadows, of the Provincial Board of Health. The system has given satisfactory service so far.

Toronto, Ont.—The cost of constructing the filtration plant at the Island has amounted to $40,000 above the original estimates. The additional expense is made up as follows:—Changes in the electrical equipment at the pumping station and the installation of the Island pumping plant at the station, $9,000; extra fill for the clear water reservoir, $3,500; additional motors, $2,000, and the balance in miscellaneous work.

Winnipeg, Man.—Owing to an accident at the pumping plant at the main city well the city was recently on the verge of a water famine, as a supply of 5,000,000 gallons of the 7,500,000 gallons is expected from this source.

BUILDINGS AND INDUSTRIAL WORKS.

Calgary, Alta.—Negotiations that have been under way for some time have been concluded and as a result the Winona Pioneer Tractor Company will erect a large plant in this city.

Edmonton, Alta.—Work will commence on a new Grand Trunk Pacific hotel at Edmonton, Alberta, which will be a third link in the chain of hotels which this company intends to build throughout Western Canada. For some time Messrs. Ross & McFarlane, architects, of Montreal and Winnipeg, have been engaged in the preparation of plans, and within a few weeks the actual construction work will begin.

Edmonton, Alta.—The directors of the Alberts College have purchased 240 acres and are about to erect a modern educational institution for boys and young men.

Fort William, Ont.—The Edwardsburg Starch Company, propose the erection of a starch and syrup factory to cost $350,000.

Hamilton, Ont.—Mr. M. S. Glassco and G. B. Jacobs are looking for a suitable site on which to erect a jam factory. The capital of the new concern is given as $100,000.

Medicine Hat, Alta.—Messrs. Bennett and Lockwood are about to erect a new hotel on Montreal Street, and W. R.

WETTLAUFER BROS. 178 Spadina Avenue, TORONTO, ONT.

Penland has commenced construction work on a new hotel on Ottawa Street. Both are three storey structures.

Nelson, B.C.—The Provincial Government will give the sum of $50,000 toward the erection of a new hospital to cost about $100,000.

North Winnipeg, Man.—The members of the Board of North Winnipeg Hospital are planning to erect a $100,000 structure that will form the nucleus of a modern hospital equipment.

Ottawa, Ont.—The management of the Capital Brewing Company are preparing to erect a new building on Wellington Street. Mr. Kuntz is manager of this company.

Port Arthur, Ont.—Preliminary arrangements are being made for the erection of an I.O.O.F. Hall on the corner of Park and Court St. Estimated cost $40,000.

Regina, Sask.—The management of the Ontario and Manitoba Milling Company have reached a satisfactory agreement with the Board of Trade whereby the company will erect a large milling plant in this city. The company have agreed to erect a mill with an output of 2,000 barrels per day, to erect a linseed flax mill and an oatmeal mill, and to erect their own power plant.

Regina, Sask.—The names of Peter Henry Van Gorp, Iowa, U.S.A., and Anson Barker, of this city, appear on the list of directors of a recently formed agricultural implement manufacturing concern. The company has a capital of $100,000, and it is expected that a building will be erected here at an early date.

Saskatoon, Sask.—The congregation of Grace Church are collecting funds for the erection of their new church. The estimated cost of this work is given at $75,000. Mr. A. C. McEwan is chairman of the committee in charge of the matter.

Toronto, Ont.—Messrs. McGregor & McIntyre are preparing to construct a steel plant on Shaw Street. This work is to cost about $40,000.

Vancouver, B.C.—Plans are under preparation for a $600,000 opera house. The building will be of steel frame construction and have accommodation for 1,550 patrons.

Vancouver, B.C.—The directors of the Vancouver General Hospital have made arrangements for the construction of a laundry addition to the buildings. The cost of this will be about $52,000.

West Toronto, Ont.—Work on a large locomotive roundhouse has been started for the Canadian Pacific Railway. When completed it will accommodate 150 engines.

Yorkton, Sask.—The management of the Hudson Bay Company at Winnipeg will erect a $50,000 store in this town.

Yorkton, Sask.—Mr. W. D. Dunlop will erect a $50,000 store in this city. It is to be red brick and cut stone 60 x 70.

BRIDGES, ROADS AND PAVEMENTS.

County of Chateauguay, P.Q.—The councilmen of this county are preparing to start an extensive programme of road improvement. About $350,000 is to be spent in this work.

Fort William, Ont.—The Island side of the new Canadian Pacific Railway bridge across the Kaministiquia River was badly damaged from the effects of a severe wind storm that swept that vicinity recently. Three approach spans were wrecked and considerable steel work torn from the concrete anchorage.

Hamilton, Ont.—Certain interests in this city are interested in a proposition calling for the paving of the highway between Toronto and Hamilton. They have estimated the cost to be $15,000 per mile, and point out that the many advantages arising from the work would be ample to offset the original outlay.

Lindsay, Ont.—It is reported that a new bridge will have to be constructed over the Pigeon River in the immediate future, as the old one was damaged by ice.

Montreal East, P.Q.—The municipal council of this town are arranging for considerable concrete paving to be done this year.

Peterborough, Ont.—The ratepayers will vote and decide the question of erecting a bridge across the Otanabee River.

Saskatoon, Sask.—The municipal engineering department are about to commence sand stone paving on the steep portions of the city around the Nutana Hills. This work will cost about $15,000.

Vancouver, B.C.—The municipal council have passed an order calling for $500,000 worth of street pavements to be laid during the next few months.

Victoria, B.C.—A delegation has been appointed to present a list of benefits arising out of the construction of a bridge across Seymour Narrows to the Federal Government at Ottawa.

Winnipeg, Man.—Plans are under preparation for the construction of a new steel bridge leading into Elm Park. The plans show a structure 521 feet long with an elevation of 25 feet above the average summer water level. As soon as the plans are ratified at Ottawa tenders will be called. The designer of the bridge is Prof. Brydon Jack, engineer of the Elm Park Company.

FIRES.

Winnipeg, Man.—The Macpherson Fruit Company's plant and storehouse was recently damaged by fire.

Winnipeg, Man.—Fire damaged the plant and premises of Messrs. Brown and Rutherford, lumber merchants. The loss will be about $25,000.

CURRENT NEWS.

Amherst, N.S.—An order for 60,000 tons of car building material has been placed with the mills of the United States Steel Corporation by the Canadian Car and Foundry Co.

This will be used in the construction of a large number of cars recently ordered from the Canadian company by the Canadian Pacific, the Grand Trunk, the Intercolonial and the Canadian Northern.

The Canadian roads are still figuring on further large equipment purchases.

Mr. George J. Bury, vice-president and general manager of the C.P.R. western division, has announced that the company has decided to increase the rolling stock to the extent of $22,000,000 to keep up with the tremendous growth of the system.

Eastern Ontario.—The Dominion Government will probably deepen the Murray Canal from Trenton to Cobourg. It is now nine feet deep and covers a length of eight miles. Survey parties are being sent out, and on their report will depend the extent of the deepening. The canal will be lighted for night navigation this summer.

Fort William, Ont.—The management of the Rhodes-Curry Company of Amherst, N.S., and the management of Edwardsburg Starch Works have been in this city looking for suitable sites on which to establish plants.

Fort William, Ont.—Should the ratepayers vote in favor of granting certain privileges to the management of the Canada Car and Foundry Company, of Amherst, N.S., the company have pledged themselves to erect a plant to cost $1,000,000, to complete the work within 30 months of the start of building operations and employ 1,000 men for the first five years.

Fort William, Ont.—The harbor tug Sarnia is now in dry dock and will have a new set of boilers installed as the old ones were condemned by the Government inspector.

Medicine Hat, Alta.—In order that the Ogilvie Milling Company's plant may be constructed with all possible speed the councilmen have had lists prepared and will request all voters to attach their names and their method of voting. In this way the delay caused by the preparation of the voters list will be overcome and should the majority pledge their support for the by-law the company will commence building operations at once.

Moncton, N.B.—A company has been recently formed in this province to work and develop the tungsten deposits. The capital stock of the concern is given as $60,000, and Mr. Samuel Freeze, Moncton, N.B., has been elected vice-president and manager. The purposes of the company are to explore the tungsten and tin ores discovered at Burnt Hill Brook on the Miramichi River, which in a measure was opened up

Announcement of the Standard Underground Cable Co., of Canada, Ltd.

Canada's New Industry

On or about May 15th, 1912 our new plant at Hamilton, Ontario, will start operation. Our Bare Wire Department will be ready to meet your requirements on that date and other departments will be started as rapidly as possible. Within three months from the above date we expect to have the complete plant running and able to meet, promptly and satisfactorily, your every requirement for the following materials:

"Standard" Products

Copper Rods
Bare Wire and Cable
Standard C.C.C. Wire
(Colonial Copper Clad)
Magnet Wire
Weatherproof Wire and Cable
Rubber Braided Wire and Cable
Varnish Cloth (Cambric) Cable
Fibre Insulated Leaded Cable
Dry Paper Leaded Cable
Saturated Paper Leaded Cable
Rubber Lead Covered Cable
Armored Cable
Terminals and Junction Boxes
Splicing Tubes and Compounds
Insulating Tapes and Varnishes
Cable Hangers, Supports, etc.

Cable Systems Installed Complete.

The rapid growth of the Canadian business of the Standard Underground Cable Co. of Pittsburg, Pa., U.S.A., has required the establishment of a Canadian company which will employ Canadian workmen. This company will, by close alliance with its Associate American Company, benefit by its experience of the past as well as future, and will maintain in every respect the high quality of its products as has been done by the latter in its 30 years of successful manufacturing experience.

"Standard" Products are specified and used by the most prominent and most particular Canadian Engineers, Architects, Contractors and Buyers. Ask a user!

Before you buy, get "Standard" prices and literature. *Just mail a card!*

Standard Underground Cable Co., of Canada, Ltd.

Dept. J - Hamilton, Ont.

last summer and which was favorably reported upon by Dr. R. W. Brock, director of the geological survey of Canada.

Montreal, P.Q.—The Board of Control have at their disposal $800,000 and will use the same for improvements that are to be included in the supplementary estimates. The major portion of this amount has come in as revenue from tax arrears and according to the civic constitution may be spent on works other than those of a permanent nature.

Port Arthur, Ont.—The Board of Education has accepted the plans of Hood and Scott, Architects, for a 12-roomed school building in Coatsworth Park. Estimated cost $50,000.

Quebec, P.Q.—The management of the Dorchester Electric Company has purchased a large lot of land known as the Taschereau property. It is said that the company intends immediately erecting their workshops on the site.

Regina, Sask.—Builders resident in this city recently held a meeting for the purpose of forming a Builders' Exchange for the province of Saskatchewan, and later to become affiliated with the Dominion Exchange.

Sarnia, Ont.—The municipal council have negotiations on with the management of a large steel manufactory. They have offered one acre of land free.

Stratford, Ont.—The ratepayers voted in favor of constructing a new market shelter at a cost of about $10,000. Other by-laws carried call for the granting of a free site to the Macdonald Thresher Company, the guaranteeing of an $8,000 loan to Mr. B. M. Williams, and to grant a loan of $5,500 to Mr. G. L. Griffith, who proposes the establishment of a sadlery and harness plant in this city. Mr. Williams requires his money for assistance in the organization of a woolen plant.

St. Lawrence River.—The Federal Government has secured by contract for another year the George Davie wrecking plant for use on the St. Lawrence River, it is also reported that in addition to this the shipping interests are taking steps to provide a thoroughly up-to-date plant, installed with wireless telegraphy and other modern equipment.

TRADE ENQUIRIES.

The following were among the inquiries relating to Canadian trade received at the office of the High Commissioner for Canada, 17 Victoria Street, London, S.W., during the week ending April 15th, 1912:—

A Glasgow firm who sell all grades, crude and manufactured, of asbestos, are prepared to act as selling agents for Canadian mine owners not already represented in Great Britain.

A Liverpool firm make inquiry for the names of Canadian manufacturers of linseed cake.

A South of England engineering firm wish to appoint Canadian agents for the sale of their centrifugal and turbine pumps.

A London firm desires to secure agencies for Canadian importers and exporters.

From the branch for city trade inquiries, 73 Basinghall Street, E.C.:—

A London firm manufacturing a new patented tobacco pipe, and also a special pipe cleaner, seeks suitable Canadian resident agents.

PATENTS.

The following is a list of patents recently granted to inventors in Canada; the list is furnished by Messrs. Fetherstonhaugh & Company, Royal Bank Building, King Street East, Toronto.

J. H. McKittrick and G. S. Ransom, cremators; P. L. Robertson, screw machines; J. M. Farrow, spike machines; T. Allatt, apparatus for making spacers for antifrugal separators; A. G. Ham and A. A. Homm, hair spring tester; M. E. Colhoun and W. Colhoun, ladies' hat fasteners; E. Carlson, harrows; T. C. Fleming, window refrigerators; E. A. Gerth, Jr., an advertising device; H. A. Gorrell, whipholders; H. C. Hogarth, filters for wells; W. H. Landon, devices for tapping trees; F. A. Leslie, water coolers and heaters; J. McLaren, cocks; W. W. Ormsbee, Jr., containers; R. Roebuck, snow plows; C. E. Smith, tile draining machines; A. E. Williams, skirt elevators.

LESSON OF THE TITANIC DISASTER.

The Editor:

Sir,—We who build on land have learned some things from the naval architects and it is barely possible that they could learn a twist or two from us. The salvation of our buildings—from fire—lies in fire-resisting construction and small units of space where fire may originate; the salvation of a ship lies in making it fire and waterproof and cutting it up into as many water-tight compartments as possible.

Collision bulkheads, false keels and midship compartments are well enough, but not sufficient. The coal-bunkers, the trunk-hold, the supply compartments, any space about a ship that can be made water-tight should be so and have only emergency openings thereto and that can be closed from the bridge or automatically. But it seems to me, and I have had something to do with ships and am not altogether without experience, and I have advocated it for years (though mariners and naval constructors have steadfastly averred I was wrong) that the decks themselves be made buoyant. Not necessarily detachable decks that would float off in a wreck, a species of raft, as has been advocated, but just buoyant decks. Steel plates top and bottom of deep deck beams, very thin plates on the bottoms to save weight, but amply effective. There would be nothing to close off, no dependence in emergency upon man or machinery, but simply unsinkable construction. Between every two deck beams would be an air compartment. Suppose the ship be rammed by another, or rip its bottom open on ice, or have its bulkheads otherwise put out of commission, it would fill with water to the first deck. There would be encountered a species of "ship-preserver," not sufficient buoyancy to sustain the entire load, but enough to slacken the load. The water would rise to another deck, more buoyancy and so on up, perhaps submerging all but the top decks, but the vessel would float. You couldn't sink it in any storm or crash Let the accident rip parts of the decks off, still, as long as any beams held together, there would be buoyancy enough to sustain the wreck. Few ships have higher than eight feet decks. Make the deck beams light of section but deep, at least a foot, and then you have, whatever may happen to the vertical water-tight compartments, at least one-eighth of the bulk of the ship in horizontal, absolutely air-tight and water-tight ship-preserving space. Supposing, to get abundant thickness of decks, you have to build ships of one deck less in maximum height, surely that "loss" is as nothing compared to the advantages of having an absolutely unsinkable ship, something our naval architects have not yet given us.

F. W. FITZPATRICK,
4200 Sixteenth St.,
Washington, D.C.

A NEW DEVICE FOR THE DETECTION OF WATER IN HOLDS OF SHIPS.

An electric alarm to signal the presence of water in the hold of a vessel is the invention of Leon Ducharme, 160 Montcalm Street, Montreal, P.Q. It consists of an ordinary electric bell attached by wires to a cylinder with a float inside. As the water rises the float rises and closes the electric circuit, sounding the bell. The cylinder can be set to ring the alarm at any depth of water from inches to feet. The alarm can also be attached to the usual discindicator.

The invention claims that on a large ship with one of these cylinders in each compartment of the ship, all attached to a bell alarm and a discindicator in the chart room, the captain of the ship would know the very second that water entered his ship and be able to act immediately.

THE TRIPLEX BLOCK

A Triplex Block hung from a temporary rigging and used for laying pipe.

What is the Life of a Triplex Block?

WE don't know. Triplex Blocks built by the Yale and Towne Co. at the very beginning—twenty-five years ago—are still in actual use. The Triplex Block of to-day possesses greater lasting powers. With its steel parts—its chain superior to any other—its non-wearing gear movement—and the guarantee of a rigorous test before shipment under a fifty per cent. overload. It will outlast the man who buys it, no matter how young he may be.

A REINFORCED CONCRETE PAVEMENT.

During the summer of 1910 a reinforced concrete pavement was laid in Plymouth, Wisconsin. The base was laid 5 in. thick and the surface coat 1½ in. thick, according to standard concrete specifications. Three unusual features of construction were used in the building of this pavement. "Pecky" cypress was used for expansion joints in place of the usual asphaltum, or tar. The 1-in. by 8-in. boards were used along each gutter and every 4 feet across the street, and at the end of the ties of the street car tracks. These boards were used as forms for the outside of the cement gutters and as a template for the crown of the street. A considerable saving of lumber as well as time in placing and removing the same was thus effected.

The reinforcement used was Triangle Mesh, Style 7 woven wire. This was placed directly on the concrete base so as to lie between the surface and the base.

The surface-finished coat consisted of granite chips from ¼ in. to ¾ in. in diameter, granite screenings from ¼ in. down to dust and Portland cement in proportion to give the densest mixture. After this mortar was spread over the concrete base and the mesh, it was troweled smooth, and while still soft the larger granite chips were cast by hand over the surface of the pavement, giving the entire area a roughened appearance. Some of the stones disappeared entirely into the soft cement mortar, leaving depressions in the pavement, while the others sank in only part way. The result was a surface which, while level enough to cause no annoyance in riding over it, was still rough enough to overcome any slipperiness of surface.

This pavement, in monolithic squares of 40 feet, is now nearly two years old, has passed through two winters, and there is not the sign of a crack or a flaw in it. It is not slippery and does not wear perceptibly. The expansion joints have worn off some, but not enough to show any abrasion of the concrete along the edges of the boards. The contract price for this pavement, including grading, was $1.23 ½ cent per square yard. The pavement was designed and constructed under the supervision of Mr. W. G. Kirchoffer, of Madison, Wisconsin.

MINING CLUB IN VANCOUVER, B.C.

The Vancouver Mining Club was recently organized by a large number of the city's well known mining men.

Mayor Findlay outlined the objects of the association, and stated that it could and would, no doubt, take a very prominent place in the mining affairs of the province. The The public had lost faith in mining schemes for they had been victimized by the wild-catter and it was the duty of the club to put before the public the real facts of the different mining activities that from time to time excite the pubilc.

Mr. R. Hedley spoke of the work of other mining clubs. The Spokane Mining Club, he said, had aided the mining interests of that part of the country to a considerable extent. The club in Slocan had also done good work in making some mining promoters retract their prospects for getting rich quick. The association, in his opinion, would make Vancouver the headquarters of all mining activities for the province and would also be a place where reliable information could be obtained relative to the mineral resources of the province.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from The Canadian Engineer for small fee.

16347—April 17—Directing G.T.R. to construct within 30 days from date of this Order spur from main line into property of Clifton Sand, Gravel & Construction Co., in Twp. of Stamford, County of Welland, Ontario.

16348-49—April 20—Authorizing C.P.R. to reconstruct 8 bridges on its Crow's Nest, Lethbridge, Havelock, Red Deer, Mountain and Farnham Subdivisions; and construct bridge at mileage 38.7, Kootenay Central Subdivision.

16350—April 20—Approving location of Kettle Valley Ry. Co. between mileage 53.92 and 65 west of Midway, B.C.

16351—April 20—Approving location of James Bay & Eastern (C.N.R.) station grounds at St. Felicien, Que.

16352—April 20—Authorizing G.T.R. to reconstruct 5 bridges on its 12th District Northern Division.

16353—April 20—Approving location of G.T.P. B.L. Co. stations on its Tofield-Calgary Branch (11 stations).

16354—April 20—Approving location of C.N.O. Ry. through unsurveyed territory, Dist. of Thunder Bay, mileage 363 to 383 from Sudbury Jct.

16355—April 19—Authorizing C.P.R. to construct its Bassano to Irricano Branch across 13 highways and diversions in Alberta.

16356—April 22—Authorizing G.T.P. B.L. Co. to cross and divert highway in N.E. ¼ of Sec. 23, Twp. 53, R. 8, west 5th. Mileage 67.9, Alberta.

16357—April 23—Directing Bell Telephone Co. to extend its telephone lines into Township of York, to provide a telephone service to said W. E. Duncan, Wm. E. Riley, and J. B. Riley, work to be completed within 30 days.

16358—April 23—Dismissing application of city of Valleyfield, Que., re G.T.R. crossing at Edmond Street.

16359—April 23—Directing city of Montreal to commence work of constructing subway authorized by Order 10455 of April 28th, 1910, not later than 15th May, 1912, same to be completed within 6 months from 15th May, 1912.

16360—April 22—Approving revised plan of C.N.R. Standard Pile and Frame Trestle, for Eastern Lines.

16361—April 22—Approving location of Algoma Eastern Rly. Station at Nairn Centre, Ontario.

16362—April 23—Authorizing G.T.P. Ry. Co. to construct spur for Fitshugh Lime and Stone Co., Ltd., near Edmonton, Alta.

16363—April 13—Authorizing G.T.P. B.L. Co. to erect stations at 18 points on its Regina-Boundary Branch, Saskatchewan.

16364—April 23—Authorizing C.P.R. to construct its Kipp to Aldersyde Branch across road allowance at mileage 83.66.

16365—April 22—16366—April 18—Authorizing C.P.R. to construct three spurs for Tyndall Quarry Co., Ltd., near Winnipeg, Man., and spur for J. Wilson, near village of Como, Que.

16367—April 24—Authorizing C.P.R. to use and operate bridge No. 87.0, Swift Current Subdivision.

16368—April 23—Authorizing London, Lake Erie Ry. and T. Co. to cross with spur line into their gravel pit London and Port Stanley Gravel Road, at Lambeth, County of Middlesex, Ontario.

16369—April 26—16370—April 25—Authorizing G.T.R. to construct siding into premises of New Burford Canning Co., Ltd., Twp. of Burford, County of Brant, Ontario, and for Ford Motor Co., Ltd., in the Twp. of Sandwich East, County of Essex, Ont. (Windsor.)

16371—April 24—Amending Order 16150, March 20, 1912, by making Lot "1" read Lot "2" in recital and operative parts of Order.

16372—April 24—Authorizing G.T.R. to construct 7 bridges on its Holmedale Branch, Brantford, Ontario.

16373—April 24—Authorizing T.H. & B. Ry. to construct spur into premises of Fretz, Limited, Hamilton, Ontario.

16374—April 25—Approving locations of G.T.P. B.L. Co.'s stations on its Moose Jaw North-West Branch, (7 station sites).

16375—April 26—Authorizing C.N.Q. Ry. to construct spur on Prince Albert Street, Tetraultville, now Montreal, Que., for delivery of carload freight to residents.

16376—April 23—Approving revised location of C.N.O. Ry. station grounds at mileage 174.5, Twp. of Storrington, Ontario.

16377—April 24—Authorizing C.N.O.R. to cross seven highways in the County of Pontiac, Quebec.

16378—April 24—Authorizing C.N.O. Ry. (Montreal-Port Arthur Line) to cross public road between Lots 3 and 4, in Twp. of Bristol, County of Pontiac, Que.

16379—April 22—Authorizing C.N.O. Ry. to cross seven highways in the Twps. of March and Torbolton, and Fitzroy, Ontario.

16380—April 24—Authorizing C.N.O. Ry. to construct spur track to proposed local freight terminals in city of Regina, Sask.

16381—April 24—Authorizing C.N. Alberta Ry. to cross with lines and tracks of its main line under lines and tracks of G.T.P. Ry. main line in N.W. ¼ Sec. 3, Twp. 53, R. 18, W. 5 M.

16382—April 25—Approving by-law No. 1 of Pere Marquette R.R. authorizing Geo. C. Conn, E.T.M., and Wm. E. Wolfenden, G.P.A., to prepare and issue tariffs of passenger tolls.

16383—April 24—Approving location of Lumber Conveyor of T. S. Sims & Co., Ltd., Fairville, N.B., across C.P.R.

16384—April 27—Authorizing C.P.R. to reconstruct 5 bridges on its MacLeod, and Cartier Subdivisions, Alta. & Lake Superior Divisions.

16385—April 25—16386—April 24—16387-88—April 25—16389—April 26—16390—April 25—16391—April 22—Authorizing C.P.R. to construct spur for Redcliffe Clay Products Co., Ltd., Redcliffe, Alta. For Whiteworth Brothers at Pilot Butte, Sask. For Sovereign Lime Works, near Angus Station, Que. For Messrs. F. W. Baird & Son, Parish of St. Jeanne de Neuville, County of Portneuf, Que. For C.P.R. on Lot 95, Parish of St. Paul, Manitoba. For C.P.R. on Lot DGS, 25, St. John, city of Winnipeg, Manitoba. For James McLaren Co, Ltd., in Twp. of Campbell, County of Labelle, Que.

16392—April 29—Authorizing C.P.R. to expropriate for purposes of taking care of traffic, lands in the Parish of Kildonan, and part of N.W. ¼ of Sec. 17, Twp. 11, R. 4, E.P.M., to establish East Yard near Winnipeg, Manitoba.

An Engineering Weekly

HIGHWAY BRIDGES AND CULVERTS.

The question of municipal highway bridges and culverts grows in importance concurrently with the increased attention given to the matter of good roads; in fact it is the cost of these highway accessories that brings the cost of road improvement higher in one locality than another, and while thought and discussion is being given, in many municipalities, to good road construction, it is an established fact, as recently exemplified by the many disasters accompanying the spring freshets, that there is a dire need for general improvement in small bridges and culverts.

A recent bulletin issued by the Office of Good Roads, U.S., by Chas. H. Hoyt and William H. Burr, takes up the whole question of highway bridges and culverts in a concise manner. Some abstracts are presented herewith. A practice which has been in vogue and which has had an injurious effect, especially in the design of highway bridges, is the method of inviting bids upon the bidder's own plans without having a competent and disinterested engineer to pass upon the designs submitted. The total weight of the steel and the amount of shop work necessary to make good, strong connections determine largely the real as well as the economical cost of the bridge. The desire to secure the contract encourages the effort, under such conditions, to make the design light enough in weight to get the contract regardless of whether the bridge is designed to carry its load with a fair factor of safety.

Still a third matter which also has had an injurious effect upon the design of bridges, and which should be avoided in all cases, is the determination of those acquiring the bridge not to pay more than a fixed amount, which has been decided in advance, without sufficient information, such as reliable engineering inspection, preliminary plans, and estimates. The plan to be observed should consist of the following steps:—

(1) The services of a capable bridge engineer should be secured.

(2) The foundations should be tested to determine suitability, bearing power and economy.

(3) The location should be determined with a close approximation and a profile of a centre line made, showing also the results obtained by testing the foundations.

(4) The load which the bridge may be called upon to carry safely, anticipating reasonably the demands and growth of the future, should be decided upon. All highway bridges, at least those on main roads, should be designed to carry concentrated loads, such as road rollers or traction engines weighing from 10 to 15 tons each, with a reasonable factor of safety. Unfortunately for the traffic of to-day many of the present highway bridges were designed to carry only moderate uniform loads, and on this account for their light appearance and their inadequacy to meet present demands.

(5) After these facts have been determined, the engineer will be able to prepare plans for the foundations, abutments, piers, and the bridge itself, all of which may be designed to meet economically the conditions of the location selected. An estimate of the cost may be made and this should in all cases be used as the basis for an appropriation for the bridge.

The amount of attention and skill to be given to the foundations for any structure depends, first, upon the size and importance of the structure proposed, then upon the loads it must carry, and finally upon its type. To avoid misunderstanding, it may be stated that the word "foundation" is used throughout this bulletin to mean the natural bed or material upon which rest the footings for the piers or abutments for a bridge, or the walls or floor of a culvert. This bed may be either rock, sand, gravel, clay, or any other natural material, or an artificial foundation prepared of logs or other material, or it may be piles driven to support the structure.

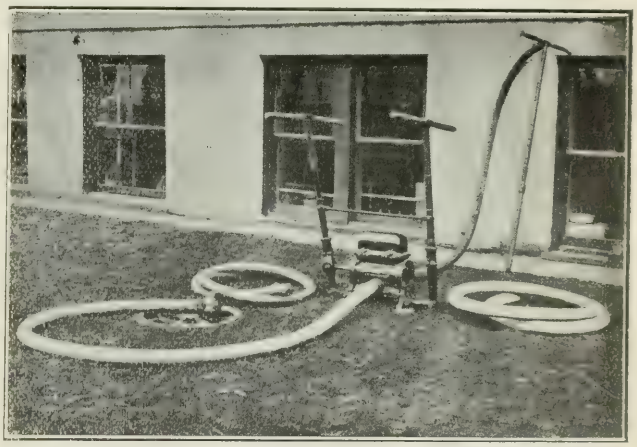

Fig. 1.—Wash-Drill Outfit for Testing Foundations.

For many of the smaller box culverts of spans varying from 2 feet to 8 feet and carrying only ordinary loads, the ordinary earth foundation is sufficient in most cases, with proper protection against undermining by currents of water. Where the streams are sluggish, however, or where the culverts are located in swamps and the foundations are soft and wet, a few logs from 10 to 12 inches in diameter, which are placed below in trenches and upon which the footings rest, add much to the stability of the foundation.

The logs, as shown in Figure 1, may be placed close together, or in many cases it will be sufficient to place them about 3 feet apart, centre to centre. The advantages of this type of foundation are that it distributes the pressure and tends to prevent uneven settlement or tipping of the side walls.

The suitability of foundations for the more important structures can be safely determined only by tests. This can be done best by digging test pits wherever conditions

will permit. In this way a better idea can be gained of the actual material in the foundation than by any other method.

Where conditions do not permit test pits, an iron rod may be driven to depths of from 10 to 20 feet, unless rock is encountered before that depth is reached. This method, however, gives very little idea of the material through which the rod is driven. A somewhat better way is to drive down 1-inch extra heavy iron pipe, which may be cut into 4-foot lengths coupled together as driven. A driving cap should be provided and the driving should be done with wooden mauls. Pipe has been driven in this manner in the winter months to a depth of about thirty feet or possibly more. The pipe, after being driven, may be pulled out with a small chain and lever, so that a sample of the material through which the pipe was driven may be brought up inside it. This material can then be examined as the pipes are uncoupled and cleared out. Material that sticks in the pipe may be loosened by placing the four-foot section of pipe in a small fire sufficient to generate steam from the moisture in the material, which, as it expands, forces the material out of the pipe. Great care should be exercised to have only sufficient fire to generate the steam slowly, or otherwise the material may shoot out the ends with considerable violence, or the pipe may burst and the flying fragments cause serious injury to persons in the immediate vicinity.

One of the best ways to test a foundation is with a wash drill outfit, consisting of a drill point to which is coupled 1-inch iron pipe in four-foot lengths. Water is forced through this pipe by a double acting force pump. Tests have been made with such an outfit to a depth of sixty feet and the wash drill may be used with or without a jacket pipe.

Figure 1 illustrates a wash drill outfit suitable for this use and which consists of a double acting force pump, with a cylinder 5 inches in diameter, a 5-inch stroke, a 2-inch suction and a 1½-inch discharge. The pump is fitted with two 12-foot lengths of suction hose with a strainer, two 12-foot lengths of pressure hose, twelve 4-foot lengths of 1-inch extra heavy iron pipe, and a drill point.

The kind of material in the foundation determines to some extent the size of the footings for the structure, with due consideration to the weight to be borne and the bearing power per square foot of the material. Rock makes the best foundation and should be used when it occurs at available elevations.

A great many tests have been made to determine the bearing power of other materials, and, while there is much variation in results, the following figures are given as indicating the range of values obtained and, in the absence of more definite information, they may be used as allowable working loads:

Material.	Bearing power (tons per sq. ft.)
Quicksand and wet soils	0.05 to 1.0
Dry earth	1 to 1.5
Moderately dry clay	2 to 4
Dry, stiff clay	4 to 6
Sand	2 to 4
Sand, compact and cemented	4 to 6
Gravel, cemented	8 to 10
Rock	200

There is, however, no definite rule by which the bearing power of a material can be determined absolutely without applying test loads and noting the amount of settlement caused by them. With the smaller highway bridges and culverts, which are the commonest built, an experienced builder is usually governed by his experience and good judgment concerning the suitability of a particular foundation to carry the proposed structure, but for any structure involving a considerable expenditure a careful test should be made.

Arch bridges or culverts especially require an unyielding foundation and are more than likely to fail unless such is provided. Consequently, they should not be built except where a good rock or gravel foundation is to be had, or possibly where a satisfactory foundation can be made by driving piles. Attention should be called to the fact that piles may be driven in an inclined position, and thus be able to resist the arch action directly.

The bearing power of piles may be determined for practical purposes, where comparatively stiff material is found, by the following formula:

$$\text{Safe load} = \frac{2\,WH}{S + 1}.$$

Here W = weight of hammer in tons or in pounds (the safe load is considered as in the same unit); H = its fall in feet; and S = the penetration in inches under the last blow. Results thus obtained, when compared with actual tests, show that this formula has a factor of safety varying from 2 to 7 or 8. It can be used properly, however, for comparatively stiff material only, for in soft material where long piles are to be used, it fails to give rational results.

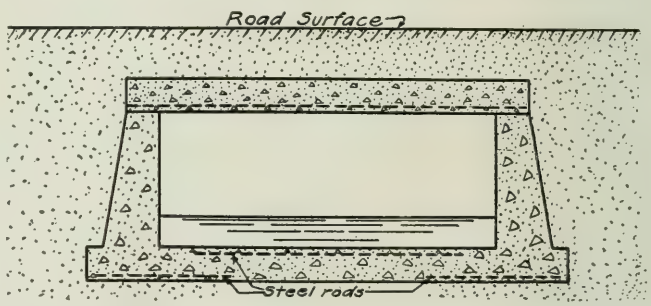

Fig. 1a.—Reinforced Concrete Floor, for Distributing Pressure Over a Greater Area and for Protecting Foundation from Erosion.

In locations where great depths of mud are found, piles are often driven that do not find a solid foundation, and the driving might be continued indefinitely, but, after leaving such piles for a few days, it is often found that several blows are required to start them again. This indicates that their bearing power has increased after the driving has stopped. It is a common practice to accept such foundations for certain structures as the best that can be secured, although they sometimes yield. In bridge construction, however, the success or failure of the structure depends much upon the foundation and too much care can scarcely be given to this part of the work.

It often happens that, after having tested the foundation and after considering the suitability of the material found, together with the elevation at which this material is available, it becomes desirable to shift the location of the bridge in order to secure a more economical substructure. For example, a suitable material for foundation may be found at a more convenient elevation in one place than in another, and this may materially reduce the cost of piers and abutments without injuring the alignment of the road seriously. In some cases it may even improve the alignment.

A survey and profile of the location should be made to establish the grade of the road. From these the amount of excavation and back fill may be determined, as well as

other quantities, distances, and elevations needed in preparing plans and in the execution of the work.

The simplest type of bridge or culvert that will be considered here is the wooden plank floor bridge for very short spans. This may be strengthened for increased spans, up to certain limits, by supporting the floor upon logs or sawed timbers. The life of timber, especially in bridges and culverts, is at best only a few years, in some cases ten, but usually, in the flooring at least, it is not more than three years. The price of timber is constantly advancing, and the liability of accidents from misplaced, worn-out, or broken plank is very great. While a timber bridge admits of theoretical design, there is no real need for its use to be encouraged, and it is the purpose of this article to deal with types of construction of a more permanent and substantial nature, such as concrete and steel.

The simplest form of concrete construction for bridges or culverts is the concrete floor or slab, corresponding to the wooden plank floor mentioned above. The concrete slab may be used for greater spans than the plank floor, and it may also be strengthened for greater spans by constructing concrete beams beneath the floor to support it. This is then known as the "T-beam" type of construction.

These types of concrete construction may be strengthened further by placing steel rods, expanded metal, or woven-wire cloth near the bottom of the slab, and steel rods near the bottoms of the beams. The advantages of using the steel reinforcement are that it has a greater tensile strength than concrete and that its location in the lower part of the concrete slab or beam brings it into tension when the beam is loaded. (Fig. 2a.) Moreover the compressive strength of concrete is greater than its tensile strength, and therefore the steel strengthens that part of the concrete structure which is subject to tensile stresses and is most liable to fail first.

This method is therefore more economical and makes it possible to bridge greater spans, within practical limits of cost, than can be done with plain concrete alone.

The application of the concrete slab is to be found first in the construction of box culverts. (Pl. V., Fig. 2.)

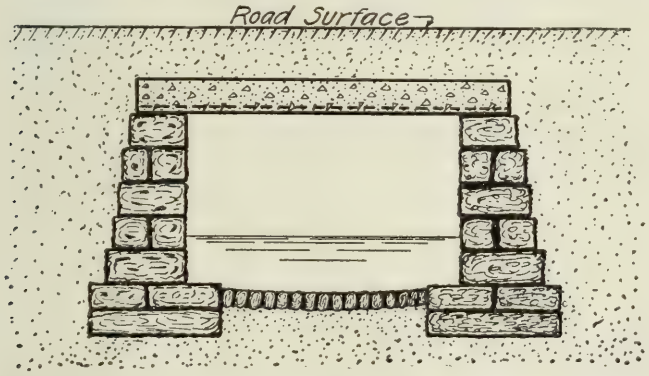

Fig. 2b.—Reinforced Concrete Slab on Masonry Abutments.

The box culvert gets its name from its similarity to a box with open ends. It has a floor, which may be of plain concrete or may be paved with stone. The two sides and wing walls at the two ends may be of plain concrete or reinforced with steel, but the cover and parapets should always be of reinforced concrete.

The sketch shown in Fig. 3a is made from a working plan prepared for a concrete box culvert, which has an opening 2 feet wide by 2 feet high.

This type of construction is practical under the majority of conditions for spans up to about 8 feet, which, as a matter of fact, forms a large percentage of all the culverts needed. Conditions may occur where it will be practicable to apply the box type, with some modifications, to greater spans than those mentioned, such as where the foundation is soft or liable to much erosion from swift currents. The floor may then be reinforced with steel, so that it will have greater strength to act as a beam to distribute the load over a greater area. It may also be extended back of the side walls to act as a footing. With suitable "cut-off" walls

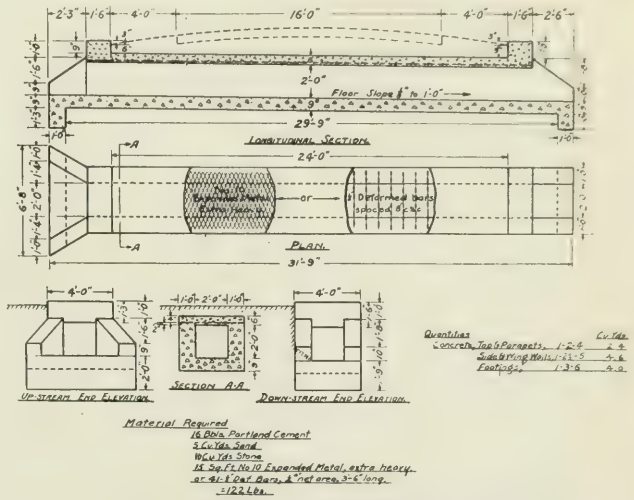

Fig. 3a.—Plan for a Concrete Box Culvert.

to prevent currents of water from running beneath this floor, the foundation will be well protected from erosion. Under such conditions this modified type, with further modifications in the cover, which will be discussed later on, may be practical for spans up to 20 or 30 feet. Figure 2a illustrates the principle under discussion. Here the reinforced concrete floor serves the same purpose as the logs, but the result is more permanent.

The length of the spans over which reinforced concrete slabs may be built within the limits of practicability and safety depends much upon the loads to be carried. The depth and amount of fill over the culvert, which may distribute the effect of the concentrated load, is also an important factor.

On main roads, where concentrated loads, such as road rollers or traction engines, are to be provided for and the depth of fill over the culvert is sufficient only to provide a cushion of earth from 1 to 2 feet in depth, the concrete slab is practical for spans up to about 10 or 12 feet, while for greater spans than this, under these conditions, other types better adapted to the longer spans should be used.

Under conditions of less severe loading the spans for the slab may be increased up to 16 or possibly 20 feet, but it does not seem advisable to use them for these greater spans in view of the possibilities of a nominal future growth of traffic requirements.

In some localities conditions may be favorable for building the footings and side walls of quarried or suitable field stone laid in cement mortar. While these will not prove more satisfactory than good concrete, it may be a matter of economy to do this, because of the saving in expense in crushing the stone for concrete. The reinforced concrete slab may be built quite as well upon such walls.

There are also many cases where masonry walls are already built, but have a poor wooden floor for the bridge. These floors may be replaced with a substantial reinforced concrete slab, which will be permanent.

Traffic should not be allowed directly on the concrete surface of the slab. Consequently it may be necessary to take off the top of the masonry abutments, so that the slab

may be set low enough to allow an earth cushion about 18 inches in depth to be placed on the concrete slab. There are also many other locations where the present bridge is set so low that it improves the grade of the road to construct the slab on the masonry abutments as they are found and then raise the grade of the road by placing the earth cushion over the slab (Fig. 2b.)

The reinforced concrete T-beam type of construction supplements the slab type and begins to be practical in point of economy at the point where the slab ceases to be economical—that is, for spans from about 10 to 12 feet and more—under the conditions of concentrated loads, such as road rollers or traction engines. This type of construction has been designed for spans up to 50 feet long, but whether or not it is practical for spans as great as that may depend upon several conditions, which must be carefully determined in each individual case.

One of the best types of culverts for spans from 10 to 30 feet long is the steel I-beam incased in concrete, upon which rests a relatively thin concrete slab which forms the cover for the culvert. The slab is designed to carry the load for a span equal to the distance from centre to centre of the steel I-beams, while the beams are designed to carry the load over the clear span from one side wall or abutment to the other.

working plan prepared in the Office of Public Roads for a 24-foot span concrete steel I-beam culvert.

Plain Concrete Arches.—The arch culvert is well adapted for locations in deep ditches or ravines, where there is an abundance of "head room," and it may be built over spans from 2 feet up. Many have been built over spans of from 50 to 75 feet in length. The Connecticut Avenue bridge in Washington, D.C., consists of a series of five arches, each 150 feet in span and built of plain concrete. A bridge in Germany has a single arch span of 215 feet, built of plain concrete. These two structures are rather exceptional, however, and are mentioned because of their general interest and not because it is intended to treat in detail of them or of structures of their magnitude in this bulletin. There are some noteworthy structures with a series of arches, and among them may be mentioned the railroad bridge at Rockville, Pa., which consists of 48 arches, each having a span of 70 feet.

The illustration shown in Fig. 3b is made from a working plan prepared for a plain concrete arch-culvert with a 6-foot span, which may be of service more often than those of larger spans.

The difference in the cost between an arch culvert for this span and that for a box culvert of the same span is not a matter of much importance. The advantage, if there is

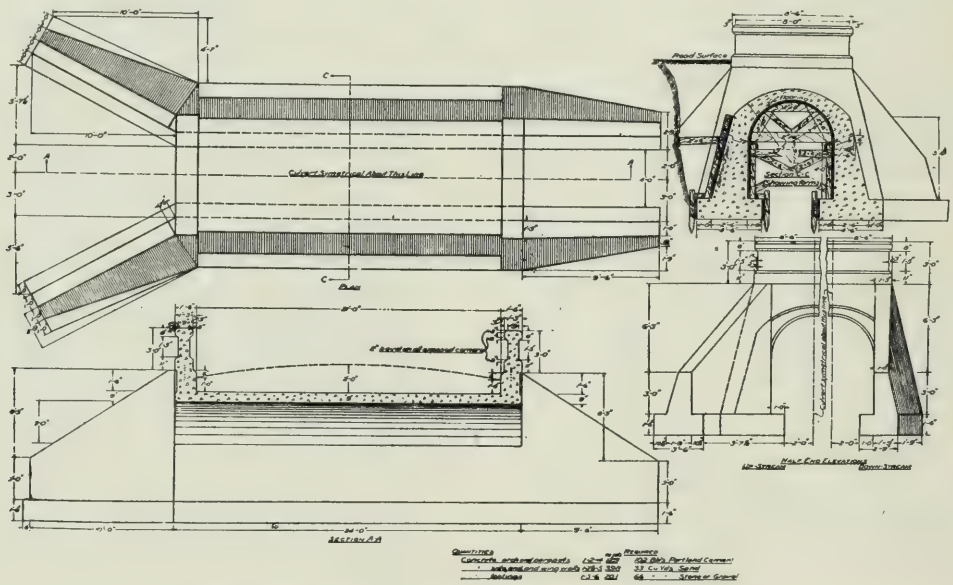

Fig. 3b.—Plan for Plain Concrete Arch Culvert.

Among the best features of this type of construction are its safety and ability to withstand severe and unfavorable conditions, such as the unequal settlement of abutments, which may cause cracks in the concrete that would cause other types to fail. In this type, however, the load is carried principally by the steel I-beams, whose strength is not destroyed by the settlement of the abutments.

Many structures of this type have been built without incasing the I-beams in concrete, but by merely painting the beams instead, to protect them from rust. The painting, however, must be repeated every few years, at some considerable expense. There is, of course, a great possibility that this painting may never be done, and the better way is decidedly to incase the beams in concrete during the construction, and thus protect them permanently.

This type also admits of arch construction between the beams for the floor system. By this means space may be saved in the depth of the floor system that may be of value in locations where the area of the waterway or the "head room" is a controlling factor. Plate VIII. is made from a

any, of the arch over the box type occurs very probably from the fact that no steel reinforcement is required for this arch as designed in the accompanying drawing.

Reinforced Concrete Arches.—The reinforced concrete arch has an advantage over the plain concrete arch in the fact that the curve of the reinforced structure may be made more nearly flat than the plain concrete arch, and thereby save in the total height of the structure. This permits it to be used where it otherwise could not. Under favorable conditions there may be an additional advantage in point of economy, although this can not be stated generally as true in all cases.

The steel reinforcement in the arch curves serves the same purpose as in the concrete slab—that is, to increase the strength of the arch rib where the concrete has excessive tensile stresses. In some cases, however, the concrete is also reinforced against compression. It is also possible, when steel reinforcement is used, to reduce the quantity of concrete in the arch rib from the amount that would be required for a plain concrete arch. The reinforced-arch type

of construction may be used for practically the same spans as stated for the plain concrete arches.

Footings for piers, abutments, and wing walls may be required for the purpose of distributing the pressure caused by the weight of the completed bridge structure and its "loadings" over a sufficient area to keep the pressure per square foot within the amount that will be carried safely by the material composing the foundation. In some cases, where the wall is designed for a gravity section—that is, without reinforcement—no footings will be required. This occurs, for example, where the side walls rest upon rock for a foundation. If the wall is of the reinforced-concrete type, then footings are practically always required. The cause for many broken wing walls is the lack of suitable footings under them.

As a matter of practical convenience in construction, footings are very generally built to "true up" uneven places in the foundation, and they are built up to some convenient elevation upon which the walls or piers rest.

The width of the footing is determined from the load to be carried and the bearing power of the foundation material. Its depth is determined from its width and the load carried; and, if constructed of plain concrete or masonry, its depth should be equal to its projection from the pier or wall, or even greater. The depth of the footing required to carry a load may be reduced somewhat by the use of steel reinforcement placed near the bottom to strengthen the projecting portions of the footing.

Another consideration that must not be overlooked in the construction of the footings is their liability to be undermined. They may, however, be protected by "riprapping" or paving around them, or by "cut-off" walls across the stream to prevent erosion of the stream bed at the location in question.

In view of the practice of the past, there is great need for the consideration of the subject of abutments and wing walls.

In many cases abutments and wing walls have not been built at all, but the four corners of the bridge span have been set on cylindrical piers or posts with possibly only a few planks to hold the earth approach. The rapid destruction of the planks and consequent sinking in of the earth approach often make dangerous holes at the two ends of the bridge. This type of construction is defective in the fact that it does not protect, but subjects the bridge and also its approaches to a greater possibility of being washed away by high water and swift currents. The damage thus caused is often more than the amount required to build substantial abutments and wing walls.

The abutment serves a twofold purpose: First, it supports the end of the bridge span resting upon it; and, second, it acts as a retaining wall for the material composing the approach to the span. The wing walls, too, serve as retaining walls and as a protection to the banks or slopes of the approach to the bridge from erosion by the water currents.

The abutment must then be designed, first, to support its load after the bridge is in place, and, second, to act as a retaining wall to resist the overturning forces of the material back of it before the bridge span is placed in position.

The wing walls must be designed to act as retaining walls. It is not the purpose of this publication to give a technical treatment of the principles of design, and it may be sufficient to say that, as a general principle, the thickness at the bottom of a retaining wall should be at least 40 per cent. of its height. This thickness should be increased if the wall is surcharged—that is, where the filling back of it is higher than the wall.

Piers.—The discussion of the subject of piers falls properly under the question of economic design. Whether or not it is economical to construct piers depends upon the relative cost of the different spans, and also upon the size of the piers required. The area of the waterway and the liability of piers to destruction by ice jams, logs, or floods, and the kind of foundation available are important matters and any one of them may be a controlling factor in the design.

From two designs for a concrete bridge with a 40-foot span and a 20-foot roadway a difference of about $200 in the cost of the superstructure alone appears in favor of building two 20-foot spans, instead of one 40-foot span. From this amount the cost of the centre pier must be taken to determine which is the more economical plan. Estimating the cost of concrete at $8 a cubic yard, including forms, it is possible to use 25 cubic yards of concrete for the centre pier. This would limit its height to about 8 feet in order to make the cost of the two structures about the same.

ELECTRIC CRANES FOR STEEL MILL SERVICE.

By E. Friedlaender.*

The rapid and cheap handling of all kinds and sizes of material by means of electric cranes has greatly influenced the making of steel products and helped considerably to reduce cost. One man can produce only about 33,000 foot-pounds of work in ten hours, where by means of a crane the same man could perform easily ten times as much work in the fraction of one minute.

Electric cranes are not nearly so wasteful in power consumption as hydraulic cranes; power is used in direct proportion to load lifted; on hydraulic cranes, however, cylinders have always to be filled, regardless of whether the hook is handling full, light, or no load. Nevertheless, the large number of gears, shafts, bearings, ropes, etc., on electric cranes cause a great amount of frictional resistance, which should not be overlooked. Good lubricated cut gears have an efficiency of from 96 to 98%, but when dry worn and out of alignment as low as 92%. Each bearing causes a loss of from 1 to 7%, according to lubrication and alignment. Rope stiffness reduces efficiency from 1 to 3%, depending on the diameter of sheaves and drums.

The total mechanical efficiency of electric cranes hardly ever exceeds 65 to 75%, and, together with electrical losses in motors, controllers and conductors, brings overall efficiency down to 50 to 60%. It is, therefore, very important to use the least number of shafts, bearings and gears possible to reduce dead weight to a minimum, and, last, but not least, keep all frictional surfaces properly machined, aligned and well lubricated. This will not alone decrease power consumption, but at the same time reduces considerably the cost of maintenance and repairs of motors and controllers. The wrong application of brakes can also greatly increase power consumption on cranes and punish severely all mechanical and electrical parts. Motors should not work against friction of brakes, but be released from it on the first step of the controller. This is easily accomplished by the use of magnetic-actuated brakes, but is entirely dependent on the skill of operator with hand or foot brakes.

More important yet is the proper speed control of crane motors; their rapid starting, stopping and reversing by unskilled men is not only very wasteful in power, but also very hard on all machinery, especially electrical. The best

* Abstract of a paper presented before the Iron and Steel Electrical Engineers, New York.

remedy is, probably, to take the control out of the hands of operators and predetermine acceleration, speed, torque and current through magnetic switches. This means, however, extra complication and expense, but will in the end pay for itself.

In regard to working efficiency of electric cranes, wherever a great amount of material has to be handled the general rule of keeping material always going in same direction should be adhered to as much as possible. It is very inefficient and costly to handle small loads at very high speeds over long distances on large and heavy cranes. In deciding on the speed of different motions we should not lose sight of the fact that the normal load hardly ever exceeds one-fourth maximum load and speed should rather be made to suit normal load; work in foot-pounds should then be made the same for the maximum load. Series direct-current motors are better adapted to this than alternating-current motors and will give, for this reason, a better working efficiency.

The proper type of girders should be selected for the work to be done by cranes. Heavy double or single-leg gantries should not be used where fast and continuous bridge work is required. It does not matter whether box lattice, single-web, or rolled-beam section is employed for girders; all will give equal satisfaction if properly designed. It is erroneous to think that lattice girders on outdoor cranes are not so susceptible to wind pressure; experience has proven that the four rows of angle braces of girders cause as much resistance as plated girders of same capacity. The fish-belly girder allows material to be used to best advantage; the square lattice girder, however, is easier fabricated, as all sections at different points are alike; it makes a rigid and stiff construction, if properly braced, with the least dead weight.

Gears, bearings and shafting may be regarded as the most important parts of cranes. On their proper design depends largely the efficiency, safety and cost of maintenance of cranes. Wherever possible, worm, bevel, split and overhanging gears should be avoided. All gears should be of steel, with standard involute-cut teeth; all high-speed gears should be made of high carbon steel properly tempered and to run in oil-bath. No pinions with less than 13 teeth should be used, as they will run rough and are liable to be mechanically weak.

Although only one-half maximum load can come ordinarily on one tooth, for the sake of longer life and safety each tooth should be made amply strong to stand entire maximum load. As all gears on cranes are worked in either direction and continuously reversed, teeth should be made so strong that they will resist absolutely all bending stresses; otherwise crystallization and breaking of teeth would be the final result. One cannot recommend too strongly to run all gears, wherever possible, in oil-bath; the resultant noiseless and easy running of the crane, as well as better efficiency and lower cost of upkeep, would soon pay for it.

All brackets and bearing supports should be made strong enough to avoid deflection of shafts and their binding in bearings. Where, on account of the light weight, it is impossible to prevent working and twisting of bearings, they should be made of swivelling type and be self-aligning.

The use of roller or ball bearings on cranes for mill work cannot be recommended, and should only be allowed where, on account of hand power, friction must be reduced to a minimum.

It is surprising that more use is not made by crane builders of oil-ring bearings similar to those on motors. Cranes equipped throughout with such bearings are always ready for work, much cleaner, do not drop oil on men and objects below, run easier and quieter, with less power consumption and cost of maintenance.

Cranes are generally handled much rougher than any stationary machinery and require continuous attention. They are naturally located in very inaccessible places, often high up, very hot, and dirty and smoky. Proper means should always be provided to give easy access to them without necessitating climbing of ladders or building columns; good stairways with railing, platforms and galleries on top for necessary inspection and repairs should always be furnished with crane structure. Crane girders should always have walks all around girder, and, if possible, trolley, to prevent slipping or falling from crane.

The use of over 275-volt currents on cranes cannot be recommended, as accidental touching of conductors is liable to be fatal. Even where electric shock is not dangerous, it may cause serious injury through fall by fright; therefore, bare conductors should be avoided as much as possible or be plainly marked by some bright colors. Means for preventing cranes from running away and wrecking themselves through wind pressure or accidental starting of motors should always be provided.

The proper location and arrangement of operator's cab is of great importance. Over yards, when material is often obstructing clear view, where operator handles material by means of grab buckets or lifting magnets without any assistance below, cab is best mounted direct on trolley. Man trolleys can be operated at higher speeds; manual brakes can easily be provided to control trolley and hoist motion, and crane can be wired easier and cheaper. Locating cab in centre on one side of crane, instead of on end of girder, gives operator often a much better view.

Crane motors are called upon to work mostly under very trying conditions, such as shocks, vibrations, frequent starting, stopping and sudden reversing, high lowering speeds, overloads, and many others, not to mention dirt, heat, rain and, last, but not least, lack of attention.

The ordinary commercial motor has been found unable to withstand continuously such conditions, and special mill-type motors had to be developed by motor builders for this work. Through co-operation with operating men, all weak, defective and undesirable features have been remedied, and there should be no trouble in getting crane motors which will stand operating conditions of mills and at the same time reduce cost of maintenance and repairs to a minimum.

Motor frames are now made entirely of steel and allow easy access and removal of armatures and fields, being split horizontally through field castings and bearings. The spider construction makes it possible to renew shaft or commutator without touching windings. Shafts are made much heavier, with larger keys and taper ends; core is pushed on spider instead of on shaft in such a way that it cannot get loose and damage windings or leads. Ample ventilation with very low core losses is provided; brush-holders have adjustable tension springs, bearings are arranged for oil-ring lubrication. Insulation is almost fireproof and will stand higher temperatures than on standard motors.

The poor commutation of high-peak current has always been a defect of crane motors, and caused frequent renewal of brushes and commutators. The introduction of interpoles on all crane motors has greatly helped to improve commutation and do away with rough and worn commutators, short-circuiting of bars, and final grounding of motors and burning of controller contacts, as well as blowing of fuses. Sparking and flashing over at brushes even with three times full-load current is not often encountered in interpole motors. The slower speed of these motors allows

quicker acceleration and stopping, with less braking effect and current consumption.

The usual practice of rating railway motors after one-hour full-load run with maximum temperature not to exceed 75 degrees centigrade, is the one that should be adhered to in most instances, especially on bridge and trolley motions, where, on account of fast acceleration of large and heavy masses, current values are liable to become very high. The half-hour rating will give motors large enough for cranes, which are generally not worked so hard and steady; as, for instance, in shops, engine rooms and over machinery in mills.

It should not be overlooked that the rate of temperature rise of crane motors is slow, in order to meet the one-hour rating, but that the maximum temperature is often finally exceeded and liable to deteriorate insulation if surrounding temperature is excessive, as is often the case in mill buildings. Manufacturers of electric machinery should state the maximum temperature their apparatus can be submitted to without any danger of injuring insulation, also what influence continuous high temperatures would have finally on motor windings.

In deciding on the proper size of a motor for certain work, not only weights, speeds and efficiencies should be taken into consideration, but, on account of rating of motors, the time of work and rest and average speed and load should be given attention. The great speed variation of series direct-current motors under changeable load should also be considered in determining size of motor, independent from the power required. The maximum speed of motion is always considerably higher than the mean speed, and could, of course, be reduced by accelerating and stopping in less time, but this would increase load of motor and necessary braking power and make wear and tear on gears, shafts and brakes heavier.

As the combined mechanical and electrical efficiency of cranes is only about 50 to 60%, not more than 22,000 foot-pounds of work can be gotten out of a 1 h.p. motor for crane work. This may give a somewhat bigger motor on small cranes, but would hardly be objectionable, as such cranes are working generally faster and more continuous than large cranes and are subjected to rougher treatment.

As the capacity of direct-current motors is mainly limited by the rise in temperature and motors are liable to exert torque greatly in excess of the capacity of the crane and cause serious breakdowns, devices should be provided to limit torque and current to a predetermined maximum and stop the motor before any harm is done.

In lowering a load the motor is assisted by the descending weight and is liable to attain very high speed, causing sparking and flashing at brushes and often serious injury to armature and field windings. The controller should, therefore, be arranged to prevent the speed from exceeding twice full-load speed. Alternating-current motors do not permit speeds much in excess of synchronous speed and can be counted on to take the place of mechanical retaining brakes. Operators, however, must be careful and not shut off power, as the motor would then be liable to attain very high speeds.

The alternating-current motor has encroached more and more into the field of the direct-current motor and successfully replaced same where speed and direction of rotation is constant. Their introduction for crane work, however, has been slow, for many reasons.

The series direct-current motor has speed-torque characteristics especially well adapted for crane service. To give similar characteristics to the alternating-current motor much of the simplicity and advantage of the alternating-current motor had to be sacrificed. The simple squirrel-caged motor had to be changed to a wound-rotor motor with slip ring and brushes. On account of closed slots, windings are tedious and difficult to put in place and to form into the required shape. Open or semi-closed slots would greatly simplify winding, but decrease efficiency of motor.

The maximum starting torque is not as great as on direct-current motors and regulation much poorer, as speed will exceed very little synchronous speed, even at no load and if maximum torque is exceeded the motor is liable to pull out and stop entirely, and cannot start again unless load is decreased.

The large magnetizing currents of alternating-current motors under all load conditions are liable to heat them up considerably when worked steadily, and must not be overlooked. These wattless currents do not represent energy and do not increase power consumption, but will heat up motors, transformers, generators and conductors. Voltage drop should be avoided as much as possible on alternating-current motors, as torque varies as the square of the applied electromotive force; this, of course, means heavier conductors on cranes and feeders than for direct-current cranes, where drop in voltage affects mainly speed, not torque. Efficiency at light loads decreases rapidly, and it is, therefore, advisable not to make motors too large for the normal work.

Although alternating-current cranes can handle a load just as delicately as direct-current cranes, they cannot perform as much work, i.e., act as quickly as direct-current cranes. Only the maximum loads can be hoisted at the same speed on both cranes, the speed of light loads and lowering being much higher on direct-current cranes. The suggestion of slowing down alternating-current motors for heavy work by means of resistance and of speeding up for light loads, to approximate direct-current crane work, means larger motors and lower operating efficiencies.

Single-phase commutator motors have about the same characteristics as series direct-current motors, and are better adapted for crane work than three-phase synchronous motors. However, they have been very little in use on account of complicated construction of motor and their inability to commutate large currents.

Since the introduction of electric motors on cranes and their ability to generate electric energy, great efforts have been made to use the generative control and do away with mechanical retaining brakes. The very same characteristics, which make series motors and their rheostatic control best adapted for crane work, are very detrimental for regeneration and do not permit very readily lowering step by step by means of dynamic braking. The self-excited series generator is slow in building up its field with resistance in circuit, allowing load to descend until the field is strong enough. Unless the operator handles the controller properly and the weight is sufficient to overhaul the drum, this rheostatic dynamic-brake control is hardly satisfactory.

By giving the series motor shunt characteristics, dynamic-brake control has become almost perfect. The operator can handle the controller as usual, and is able to lower either the empty hook or the maximum load step by step at any desirable speed. By driving the armature and field in two separate circuits and exciting fields separately, counter electromotive force can be lowered or raised above line voltage as desired. This, however, requires large rheostats in addition to controller resistance and brakes, which will release the motor when current is at its minimum value. The use of shunt brakes, or placing of series brakes with resistance directly across the line, would easily overcome all trouble.

OVERHEAD CHARGES.*

By Prof. Mortimer E. Cooley, Dean of the University of Michigan.

In the valuation of the property of public service corporations aggregating $1,100,000,000, I have had the honor to serve both the public and the corporation. By far the greater part of my work along these lines has been done for the public; and having in the beginning and for about seven years worked exclusively for the public, I naturally approached the problems from the side of the public and, it might be said, as against the corporation. It very soon became apparent, however, that either the contentions of the corporation were sadly at variance with the facts or the public was densely ignorant of the true state of affairs; and henceforth the real problem was to discover as nearly as might be the common ground upon which there could be no serious disagreement.

It must be said at the outset that the responsibility for misunderstanding rested largely if not wholly with the corporations. Their business is of a technical character and not readily understood by the layman without explanation, and the corporation official had not in the past felt called upon to make explanations, at least not of the kind inspiring confidence in the public mind. This is now seen to be true, and while not too late for correction the failure to comprehend its importance, even its necessity, at an earlier date has led to the very serious controversies of to-day, wars they might be called, between the public and the public service corporation. The public is fighting for what it honestly believes its rights and the public service corporation is fighting for existence.

Setting aside the mistake which has been made in the past of keeping the affairs of the corporation in a sealed book, any fair-minded man who will make a study of the problem with all the information now available must inevitably reach the conclusion that the present attitude of the public toward the public service corporation is as much at fault and quite as blamable as was the secretiveness of the corporations in the past. The public, slow to wrath, is a mighty force when once aroused and can no more be resisted than the ocean tide. It, however, reaches its height and begins to ebb in due course, and it remains to be seen whether in the future we shall profit by the experience we are now having and establish conditions far more stable, so stable in fact that a similar situation cannot again arise. Much swifter progress could be made in bringing the war to an end if the fight could be carried on by the master minds on both sides. History reveals that unfortunately that is not the way wars are conducted. Politics has prolonged many a war and delayed the re-establishment of peaceful conditions after the war itself was ended. The political charlatan thrives at such times and seeks to maintain the conditions necessary to his nefarious existence. But he is not the only parasite; there is also the unprincipled expert, scientific expert he calls himself, whose expertness lies in being able to set up an array of figures in apparent proof of any result desired or required of him by his boss. If anything he is more dangerous than his boss, because his weapons are figures juggled to suit his purpose, and only to be refuted by an expert on the other side, who, however honest he may be, is sure to be considered by the partisan equally unprincipled.

Opportunity for the Accountants and Engineers.—The real forces effective to end this conflict between the public and the public service corporation are the accountants and engineers—not to end it, perhaps, but to point the way so that the man who really desires to be fair may have before him the facts upon which to base his judgment. The public as a whole is honest and fair—it is only individuals who are dishonest and unfair—and once the ignorance of the public has been dispelled the true and correct solution will be in sight. But the engineer and the accountant, while in the main honest enough, are not to escape responsibility in some measure for their ignorance.

The engineer has not always dared to tell the whole truth, fearing it would not be believed, and that his reputation would thereby suffer. He has therefore told but a part of the truth, and now when the necessity for the whole truth is imperative his task is much increased, he being obliged to explain his earlier position. In many, and it is to be hoped in most, cases this earlier position of the engineer was due to ignorance of the real facts, or more likely to knowledge of only a part of the facts. It is only comparatively recently that the engineer has been called upon to work with the accountant and the financier in the development of all the facts in the creation of the property of a public utility corporation. Is it therefore to be wondered at that the public has remained in ignorance?

The accountant's share of the responsibility cannot be said to be due to ignorance or to any fear that his reputation might suffer from a disclosure of all the facts. It is repugnant to the average mind to wrestle with the mass of figures required in setting up the details of accountants. It should be possible for the man of average intelligence to enter an account and find there the essential things required in comprehending the cost and the value of a property and the expenses of operating and maintaining it. It should not be necessary for an expert accountant to spend months digging through accounts for the necessary data upon which to base costs and values. This criticism does not bear today with the force it did in earlier years, because of the study and effort on the part of accountants for a number of years past to devise methods or systems of accounting which will afford almost at a glance any particular kind of information desired. The accountant has rather been the custodian of facts, the keeper of the storehouse as it were, but now he must perform the additional task of preparing the facts for consumption. The facts required by the public at this time are in themselves simple enough; the difficulty lies in devising means to disclose them so that they can be easily comprehended.

Appraisals of Property.—The public desiring to inform itself as to the cost and value of a public utility property requires an appraisal to be made, that being the simple and obvious way to go about it. Prior to 1900 the principal appraisals of this class of property were of water-works. In practically all cases this investigation was made to discover the value of the plant with a view to taking it over from private to municipal ownership, the condition for the transfer being usually set up in the franchise. These appraisals were usually made by engineers, it being customary for the municipality and the company each to choose one or two and these to choose another who should act as chairman and cast the deciding vote in case of a tie. All too frequently the appraisers entered upon their work as advocates, each for the side choosing him, and the appraisal became a controversy, which had finally to be settled in the courts. The decisions handed down have become the law of the land which, while almost wonderfully good in the majority of cases, is not altogether applicable as precedents to many of the cases arising to-day.

The chief object in those days was to arrive at the value of the property, which included the so-called "going value" of the property. "Goodwill" was another element considered.

*Abstract of paper read before the American Electric Railway Accountants' Association, Atlantic City, N.J.

But to-day, and since 1900, appraisals are made not alone to discover the value of the property, but the cost as well. The appraisal to-day is not so much for the purpose of transferring the property from private to municipal ownership, although that is the alleged object in a few cases, but for the purpose of taxation and rate making and to determine the extent to which the issuance of securities can be authorized. Obviously it is to the interest of the corporation to have a low value for taxation and a high cost for rate making and the issuance of securities. But of course both cannot be had except as the facts justify them. And right there is the first obstacle encountered by the public and the corporation in coming to an understanding. The public fails to see any difference between the cost and the value and argues, not without some show of reason, that if the property has a certain value for taxation it surely ought not to be different for rate making and the issuance of securities. The fact that the corporation fights to keep its figures down in the one case and up in the other no doubt contributes in no small degree to the attitude of the public toward it. It is, therefore, important to discover first if there can justly be any difference in the two cases and, second, if so to what extent can such differences properly exist.

It is not so much my purpose in what follows to say what ought or ought not to be done as to indicate the things which must receive consideration in determining what ought or ought not to be done. The average individual thinks of the value of a public utility property as consisting merely of the things which can be found and inventoried; in other words, he thinks of the value as being made up of the physical elements only. For many it is quite a long step to add any intangible elements or to consider the capacity of the property to earn a return on the investment. The farmer, for instance, in placing a value on his land unconsciously considers how much of the different things can be raised, the first element of value being its earning capacity. Then he considers the physical structures, house, barns, fences, drainage equipment and stock and other things which he has had to add from time to time, and for which he has had to invest capital in one form or another. I venture to say that if a complete analysis of a farming property could be had, starting from the beginning, most if not all of the elements, or their equivalents, would be found the same as in a public utility property. The first thing, therefore, is to realize that the value of such a property does not lie in the physical elements alone, independent of their earning capacity.

Point of View of the Utility.—It aids materially in one's quickness of understanding to assume one's self to be the corporation and then to take the steps successively as they come in building up the property, putting it into operation and carrying it along until it becomes self-sustaining. One readily comprehends the outlay necessary to acquire the rails, the ties, the overhead work and the power plants and the labor involved in their installation. One does not, however, so readily comprehend the other outlays which, although they are not seen as tangible elements, are just as much present as the tangible elements themselves. These other outlays are in general grouped under the name of "overhead charges." The term is somewhat elastic; its scope will be greater or less, depending on the extent to which certain charges are considered as a part of the physical structure itself. For instance, the elements of contingencies and contractors' profits, if not included in the cost of the physical structure itself, would have to be considered as overhead charges; both are present and must appear in the cost somewhere. The practice of valuators is not uniform, some preferring to include those two items in the cost of the physical structure and others to separate them and add them as a percentage. Occasionally an appraisal has been made with no separate charge appearing to cover contractors' profits, but in such cases the unit costs have included them or the items have been taken from the contracts awarded on bids invited for the work. The contractor's bid includes, of course, both his allowance for contingencies and for profits.

A usual allowance for contractors' profits is 10 per cent. on the cost of the work. The item of contingencies varies with the nature of the work. There should, indeed, be two items of contingencies, one a construction charge, the other an inventory charge. The former may vary in an inventory from 1 per cent. to 2 per cent. to as much as 20 per cent. or 25 per cent. An example of a low percentage for this item might be found in the cost of a power unit the contract for which calls for the unit completely installed and operated for a time before acceptance, but in such a case the contract price includes a liberal charge for contingencies, as no contractor would think of undertaking the work without protecting himself against unforeseen expenses incident to such work. The same thing is true in the case of cars which are delivered on a contract. An example of the higher percentage may be found in a foundation or in a job of piping or station wiring. Making due allowance for varying conditions, an average charge of 5 per cent. on the cost of all items to cover construction contingencies is as low as it is safe to go. In the same way and for similar reasons another 5 per cent. should be added to cover inventory contingencies, making a total charge of 10 per cent. for contingencies.

It has been frequently argued that little or no allowance should be made to cover omissions from the inventory, the reason given being that the work has been done and all the items can be found and listed. But such is not true in fact. When the costs were figured in the first place complete plans and specifications were available, and quantities could be taken off and the difficulties of construction studied in detail. In making the inventory almost always no plans and specifications are available and there can be no comprehensive study from the work as done which will lead to the results obtained from a study of the plans without a liberal allowance to cover contingencies. Indeed, it frequently has been found desirable if not necessary to recreate the plans from the work as done before undertaking to value the structure. Numerous instances might be cited to show that even a total of 10 per cent. was an insufficient allowance to cover all kinds of contingencies. The use of a smaller percentage can be justified only when the unit costs have been determined from similar plants the actual costs of which were known, and in such cases the contingency item or a part of it will be found in the unit costs themselves. But even when the unit costs are such as to cover construction contingencies there remains the inventory contingency which must be added to complete the cost of the physical structure as it is listed in the inventory.

The charge for engineering likewise is a desirable item. Engineering usually covers the making of surveys, plans, specifications and estimates, inspection of materials and the supervision of actual construction work as it progresses. There should be added a charge for engineering in connection with each general item of the inventory which, depending on the nature of the work, may vary from 1 per cent. to 2 per cent. up to 10 per cent. and even more. Then there should be added to the cost of construction a general item of 2 per cent. or more to cover engineering not assignable to individual parts of the inventory. The total charge for engineering will in some localities not exceed 4 per cent. or 5 per cent., but in other localities it will go much higher.

Many of the earlier appraisals went no further than to include the cost as determined from an inventory, to which was added an allowance for contingencies and engineering.

The depreciation of the physical elements due to wear and exposure to the elements was then determined usually by assigning to each element a life and considering its age at the time of the appraisal. The result thus obtained was called the physical value of the plant, and to this were added any "going value," if it could be determined, and sometimes another value, that of "good will." The appraisal was then considered complete. While such a value, an approximation at best, might have sufficed in the older days of liberal dividends and little or no scrutiny of the affairs of a corporation, it in no way meets the conditions as they exist in these days of public demand. The public service corporation is no longer free to do merely the things which its management considers advantageous to do from the standpoint of insuring dividends. It is compelled to do things which involved expenses of such variety and magnitude that in some cases not only are the profits reduced to a point of practically no dividends, but there are insufficient net earnings to pay the interest on the bonded debt. It is this condition of things which renders it all-important both for the public and the corporations that the elements of cost and of value in a public utility property be made perfectly clear. This is the great problem of the day and it is all-important in that it affects the life itself of the public utility. It is equally important whether the utility be owned and operated by a municipality or by a corporation. The public service corporation is but the agent or servant of the municipality, and what affects one must of course affect the other.

Full Understanding Required.—The first thing necessary, therefore, for the man who would attempt to regulate the conduct of his agent or servant is to fully understand what is required of him. If a man has been successful in his own business it was due to careful study and a mastery of details. It passes comprehension that such a man should assume to direct or control a business about which he has but a smattering of real knowledge. If every man would apply or allow to be applied to a public utility the same principles which he applies to the conduct of his own affairs there would be little to complain of. What, then, are the things which the honest man should understand if he is to act wisely in the regulation of a public utility? Let that man put himself in the place of the public service corporation and see for himself the things it would be necessary to do. Imagine that he starts at the beginning. He is an active, perhaps a prominent, man in his community. He conceives that an electric street railway system would be a good thing for the community. He talks it over with some of his friends, the matter is carefully canvassed and the public sounded to discover whether there is any real demand for street cars. This may have taken several months, and required considerable time to be given to the project either by the man himself or some one employed for the purpose. Thus is a preliminary expense incurred.

It having been determined that a street car system is desirable in the interests of the public, its promoters must consider whether it would be desirable in the interests of the man who has money to invest. That is settled at once by the rate of return likely to be realized by the investment. Such a rate must be sufficiently attractive to divert money from other channels, and moreover the rate must be sufficient to meet any additional hazard not encountered in the ordinary channels of investment. A careful study must then be made of the routes, the necessary surveys and general plans worked out preparatory to obtaining a franchise. Thus a further item of expense is incurred. The franchise being obtained, it is necessary to obtain consent from property owners, which may be a very heavy item of expense. All of this work may have taken a year or several years. It is the development period of the project and all items of expense legitimately incurred are proper elements of cost to be charged to the property. Such items of expense do not appear in the inventory of physical elements of a property, and they are therefore an overhead charge. The extent of this charge necessarily varies greatly with the locality. Property consents alone have been found in some localities to run as high as $2.50 per front foot; in such a case the preliminary or development charge might easily reach $20,000 or $30,000 per mile, which would represent a percentage quite beyond belief by the average man. It is not yet practicable in most cases to separate the item of the development period so as to discover whether it might fairly be represented by a percentage of the cost varying between any definite limits. This item is altogether too frequently ignored even by experienced appraisers; or if not ignored it is included in the item of organization expenses, which item also frequently includes legal expenses. When so included the combined items may vary from 2½ per cent. to 5 per cent. and more, depending on locality.

The items of insurance, both fire and casualty, are now quite generally recognized as proper charges, the amount varying usually from one-half of 1 per cent. to 1 per cent.

Interest during construction curiously enough does not appear to have been thought of in the earlier days of appraisals, but the man of business knows without any argument that money cannot be borrowed without interest. The only question is on the time it should run. Six per cent. is accepted ordinarily as the rate, and the time is one-half the construction period. If, therefore, the construction period be one year the rate would be 3 per cent. of the total amount expended, assuming that the expenditures start from zero and mount uniformly to the total at the end of the year. The construction period in a street railway system is ordinarily taken as the time required to complete the power plant. This in a plant of any magnitude may be from two to three years. Along with interest the taxes must be included or set up separately, and it should not be forgotten that the interest item must also include the interest on the expenses incurred during the development period. Thus in a plant in a large city the interest charge might easily reach 9 per cent. or 10 per cent.

A BOOK OF VERSE.

Poetry is not much in the engineer's line. The Methodist Book and Publishing Company, Toronto, however, have just issued a volume entitled "Rhymes of the Survey and Field," which will appeal to those of the engineering profession who have been connected with outdoor and survey work. The author, Mr. G Blackstone Field, is an engineer at present engaged on surveys for the Canadian Pacific Railway in the vicinity of Wilker, Sask. The Rhymes deal with different phases of the fieldman's life in camp and on the road, and are written in a style very similar to Robert W. Service's poems.

PEAT FUEL IN DENMARK.

An English syndicate is spending large sums of money trying to develop coal turf from the Danish peat bogs. It has been estimated that Denmark can thus supply itself with fuel for 100 years to come, the bogs in this country containing about 300,000,000 tons of turf suitable for heating purposes.

The company is building its first factory in Zealand, where work has already started. The company has a capital of several million dollars and it is said that its operations will be extended to France, America, Russia, Siberia and China.

SELECTION OF A WATER-WHEEL UNIT.

By O. B. Coldwell.

INTRODUCTION.

One of the most interesting problems with which the engineer of a company utilizing water power has to deal is the selection of the hydraulic equipment for his plant.

With the exception of the tangential wheels used in high head work on the Pacific Coast and a few sections of the United States, it might be said that, for a good many years, most of the water wheels used in this country were located on streams near tide water and operated at heads below 60 feet (18 m.) Water wheels during this period were manufactured very largely along so-called "cut and try" lines and there were no well-developed principles of design. The experience gained during these early years of water turbine building and the knowledge derived through testing and operating such wheels has contributed very largely to the development of the art of water wheel building as it is known to-day.

Water wheels of this early period were for the most part used in mills of one sort or another to drive machinery which did not demand a very high degree of speed regulation. High efficiencies were occasionally obtained, but usually but for one point of load or for an exceedingly short range of load.

In recent years, due to the more general utilization of the water powers of the country and to the perfection of high-tension transmission of electricity, there have been many developments on the upper stretches of our power streams where the slope in feet per mile is very much greater and higher heads are more common. The operating heads of these plants range from say 60 to 400 feet (18 m. to 122 m.) for intermediate heads, from 400 to 1,000 feet (122 m. to 305 m.) for high heads and from 1,000 to perhaps 2,500 feet (305 m. to 762 m.) for extreme high heads.

Changed conditions are now met with. Many of these modern plants are of the hydroelectric type, requiring a nicety of regulation which was not known in the early period. Economy in the utilization of water becomes an important factor due to the characteristics of stream flow and the necessity of utilizing the available water to the maximum possible extent for the purpose of keeping the cost down to a minimum. In many such developments that part of the total cost brought about by the fixed charges on the investment exceeds greatly the part due to operation, and it is, therefore, important that the output be as large as possible. On account of the characteristics of the loads ordinarily imposed upon hydroelectric plants, the extent to which water can be stored has a marked influence upon the cost of generation in such plants.

Due to the various important factors mentioned above, there has been gradually perfected the highly specialized engineering science of water wheel design.

The object of this paper is not, by any means, an attempt to tell how to design a water wheel, but rather to discuss the features entering into the particular design which will best meet the conditions for which it is intended, and to point out the information which should be furnished by the purchaser to the waterwheel designer to enable him to plan the most efficient unit.

Although we have passed from the earlier period mentioned above into the later, in which a more thorough appreciation of the water wheel problem is required, it still remains a fact that in many instances very little engineering is being used in the selection of water wheels. This is perhaps due to a certain extent to the practice of manufacturers themselves in issuing trade catalogues. Those catalogues contain information regarding the discharge of water and horse power developed at given heads by various sizes of runners, but do not take into consideration such factors as variations in speed, variations in head, or other features which may have a large influence on the selection of the proper wheel. As a result, due to the custom of relying on catalogues in the past, many water wheels at present are being ordered directly from these catalogues without due regard and study being given to the conditions which should enter into the selection of the wheel.

In the following discussion an attempt is made to show that in general more thought should be given and more precise methods applied in selecting water wheel units.

Elementary Hydraulic Principles.—Having made the foregoing presentation of the scope it is intended to cover in this paper, there will now be brought to your attention a few elementary hydraulic formulas which will be employed later in the discussion. The elementary principles which are involved in these formulas should preferably be known and understood by the one selecting the wheel in order that he may properly cope with the questions which he should solve and be able to more intelligently place his order. The formulas given here are not, by any means, all of the formulas which enter into the complete solution of the hydraulic problem.

To begin with, a water wheel is a device which is placed in the path of falling water for the purpose of abstracting energy possessed by the water, due to its fall and weight, and delivering as much as possible of same to the shaft as mechanical energy.

The energy possessed by the water may be expended and made manifest as power as follows:

1. By allowing a quantity to pass from a higher to a lower level practically without velocity.

2. By the momentum possessed by a quantity of it traveling at a velocity caused by the head.

3. By pressure of the water due to head acting on an area through a space.

What usually takes place is a combination of these ways of expending hydraulic energy and making it manifest as power.

Total head is the difference in elevation between headwater and tail-water and is usually expressed in feet. This total head may be divided in general into three parts, as follows: friction head, discharge head, and effective head.

Friction head is that part of the total head which is applied in overcoming the friction in the water passages leading to and away from the wheel, as in the passage away through the racks, entrance to penstock, in the penstock itself, through the guides and buckets, and in the discharge tubes.

Discharge head is the head at which the water leaves the draft tube and enters the tail-race. In well designed wheels this is usually of small magnitude, but it is readily seen that this head is an absolute loss.

Effective head is the part of the total head left to be applied to the wheel itself for effecting the energy transformation after the friction and discharge heads are disposed of.

In the case of Francis turbines, the effective head includes the draft head or effect of draft tube; a tangential wheel has no draft tube.

* A paper presented at the Pacific Coast Meeting of the American Institute of Electrical Engineers, Portland, Ore., April 16-20, 1912.

Friction head loss in a steel pipe is found approximately by the following formula:

$$\text{Friction head} = \frac{l\ v^2}{3{,}000\ d}$$

l = length of pipe in feet.
v = velocity in pipe in feet per second.
d = diameter of pipe in feet.

When the quantity of water available in cubic feet per second and the effective head acting on the wheel are known, the approximate horse power is given by the following formula:

$$\text{h.p.} = \frac{\text{quantity} \times \text{effective head}}{11}$$

This assumes a wheel efficiency of 80 per cent.

The stream flow upon which the plant rating is based should receive careful consideration and study. If possible, accurate flow data over a number of years should be obtained. Many expensive mistakes have resulted from not giving sufficient weight to this matter.

Other fundamental formulas which might be mentioned here are:

h.p. $\propto \sqrt{h^3}$

rev. per min. $\propto \sqrt{h}$

Quantity in cubic feet per second varies as $\sqrt{h}$

Velocity in feet per second $= c\sqrt{2gh}$ where c is a constant having values dependent upon conditions of discharge. It is unity in value when water is discharged freely through a perfect nozzle, and in such a case, the velocity is the same as that acquired by a freely falling body and equals approximately $8\sqrt{h}$.

It might be said that the formula $v = c\sqrt{2gh}$ is the most important of all hydraulic formulas, as it enters into all calculations and designs of water wheels.

Types of Water Wheels.—We will now briefly mention some types of water wheels and the principles on which they act.

a. Gravity Type.—This type of wheel includes breast, overshot and undershot wheels. The efficiency of these wheels is often quite good, but the speed and power are extremely low, and this type is, therefore, not adapted to ordinary present-day conditions. We will, on this account, give it no further consideration.

b. Impulse Wheels.—This type of wheel includes the Pelton and Girard wheels. They are kinetic energy wheels, that is, the momentum of the mass of water in its impact with the runner buckets is the main principle utilized in the energy transformation.

In the Pelton type, the water strikes tangentially upon the buckets, while the Girard types, the water passes through the runner radially outward; an extremely careful design is necessary for this type.

c. Francis Type.—This wheel is a combined potential and kinetic energy wheel, the water passing either inwardly or outwardly through the runner. The wheel rotates partly from velocity action and partly from reaction due to pressure and consequent acceleration in the buckets. The so-called Smith, American, Holyoke, Jolly, Hercules, McCormack and Victor turbines are well-known wheels of this type. They received the above names years back when the so-called "cut and try" methods were used rather than theoretical design. This does not mean that these wheels are not good wheels. Much credit is due to the enterprise and achievements of the pioneer manufacturers responsible for their development.

Design and Calculations.—Hydraulic principles properly applied bring the design of a water wheel within the full grasp of the engineer. Hydraulic formulas contain many constants and coefficients, and it has taken time, patience and experience to gain a correct knowledge of the proper values of these. But once having gained a knowledge of them for various types of nozzles and surfaces, a full knowledge of velocity relations and correct design can be arrived at.

In general, the calculations necessary in designing a water wheel runner will be left to the manufacturer and will not be taken up here, but we will discuss briefly the manner in which the speed of a turbine runner is affected by the angles of the buckets and guides, as we will use this later.

Reference may now be made to the sectional drawings Figs. 1, 2 and 3, and the corresponding runners, Figs. 4, 5 and 6. These sketches show the general designs of the guides and runners for three types and angular relations of same. The diameter is the same for each runner.

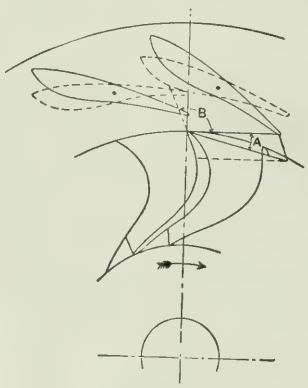

Fig. 1.
(See Fig. 4 for Runner.)

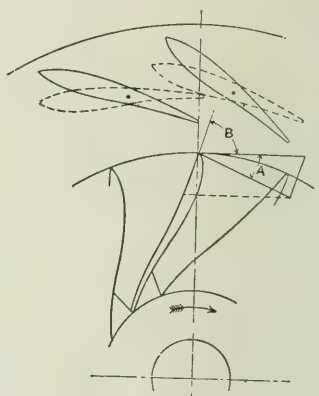

Fig. 2.
(See Fig. 5 for Runner.)

Let A equal the angle between the tangent of the periphery of the runner and the direction of the flow of the water as it leaves the guides.

Let B equal the angle between the tangent to the periphery of the runner and the entering edge of the runner bucket.

Let V equal peripheral velocity of the runner in feet per second.

Let H equal effective head in feet.

Led D equal diameter of runner in feet.

Then

$$v = 52\sqrt{H}\sqrt{\frac{\sin(A+B)}{\sin B \cos A}} \text{ (approximately)}$$

$$\text{rev. per min.} = \frac{60\ v}{3.41\ D}$$

A consideration of these two formulas clearly indicates that the diameter of the runner and the rev. per min. depend upon the angles chosen. Therefore, with a given diameter, to obtain rev. per min. angles must be chosen to suit and the design of the bucket made to correspond.

It is convenient to use in the process of design a head of one foot as a basis for calculations. Having made calculations for unity head, values for other heads are readily obtained by using the three fundamental formulas given heretofore.

h.p. $\propto H^{3/2}$

rev. per min. $\propto H^{1/2}$

Q $\propto H^{1/2}$

The choice and design of a particular type of runner to suit some given fixed condition can be based upon what is

known as "specific speed" of the runner. The formula for specific speed is

$$K = \frac{\text{rev. per min. } \sqrt{H}}{H\sqrt{H}}$$ and may be defined as: the speed at which the runner will operate when delivering unity horse power under unity head.

A given specific speed comprehends a particular design of one type of runner only. The designer fixes the angles A and B for each particular specific speed and thereby arrives at standard designs based upon specific speed. Probably no two designers would use precisely the same angles, and, therefore, velocity relations, bucket widths and openings will vary in runners intended to give equivalent performance. The variation, however, is not great.

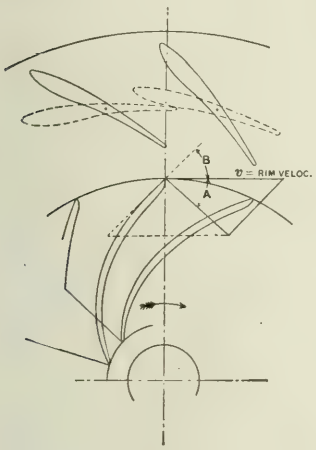

Fig. 3.
(See Fig. 6 for Runner.)

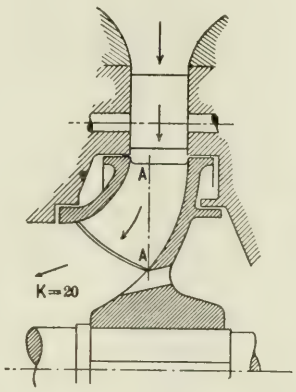

Fig. 4.
(See Fig. 1 for Section A-A)

Let us consider Figs. 1, 2 and 3. Fig. 1 is a runner of low reaction type which would be used on relatively high heads. Notice that the angle A of water leaving the guides is small, and the angle B of the bucket is greater than 90 degrees. These angles are selected to give a low peripheral velocity of the runner. If the values of the angles, which are approximately 14 degrees and 110 degrees, are used in solving the velocity equation given above and H is taken as unity, it will be found that v equals about 50 feet per second for this particular runner.

Fig. 2 is a runner of moderate reaction and is a type which would be used on lower head than the runner of Fig. 1. The angles in this case are selected to give a higher peripheral velocity of the runner. If values of the angles A and B, which in this case are approximately 23 degrees and 73 degrees, were substituted in the velocity formula, it would be found that v equals about 56 feeet per second.

Fig. 3 is a runner of high reaction, and would be used on lower heads than the runner in Figs. 1 and 2. The angles in this case are selected to give very high peripheral velocity. Their values are approximately 42 degrees and 46 degrees and the value of v if worked out by the formula is found to be about 71 feet per second.

A comparison of Figs. 1, 2 and 3 shows that as the type of runner changes from low reaction to high reaction the bucket angle changes from a forward curved bucket to a backward curved bucket. It is, therefore, evident that in order to get a high peripheral velocity, a backward curved bucket must be used.

Comparison of Figs. 4, 5 and 6 shows that in the case of the low reaction runner the width of the bucket is small, while in the case of the high reaction runner we have a very wide bucket for the accommodation of the larger quantities of water necessary. For relatively low power wheels, angles are used to give relatively low speeds, since these wheels are ordinarily used on high head work and small quantities of water are met with. For relatively high power wheels angles are used to give relatively high speeds since these runners are ordinarily used on low heads.

It will be noted that the runner in Fig. 4 is one with a specific speed of K = 20; in Fig. 5, K = 45; in Fig. 6, K = 75.

Francis turbines can be used for values of K as low as 12; for lower values tangential wheels should be used. This limiting value, however, is not well defined.

A manufacturing company ordinarily has available a number of types of runners, each of which has a particular value of K. Each one of these types is used for certain conditions and what is good in one case would probably not be suitable in others. The reasons for this will be brought out more in detail later on.

Fig. 7 is entitled "Comparative Efficiency Chart." On this chart the load on the runner is plotted in per cent. of its full load, while the efficiency is plotted in per cent. of the efficiency at which the wheel operates at full load. Curves for K = 20, K = 45 and K = 75 are plotted. It is readily seen on examining these curves that the efficiency will depend very greatly on the type selected. Let us say that we have a type No. 2 wheel installed, that is, a runner with K = 45; it will be noted that when this runner operates so as to give 60 per cent. of its full load the resulting efficiency is 103 per cent. of its efficiency at full load. If its full load efficiency is say, 82 per cent., then the efficiency of this runner when operating at 60 per cent. of full load is 103 × 0.82 = 84½ per cent.

Type No. 1 is used on high head work, No. 2 on medium head work, and No. 3 on relatively low heads. It is readily seen by examining the comparative efficiency chart that the efficiency which will be obtained by the employment of these different types varies through a considerable range.

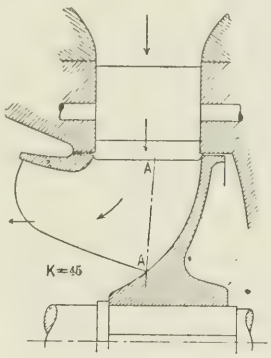

Fig. 5.
(See Fig. 2 for Section A-A)

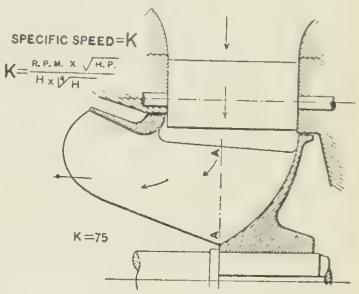

Fig. 6.
(See Fig. 3 for Section A-A)

A runner with K = 45 could not be used for very high head work and would, therefore, not enter into consideration for a plant which is going to operate at, say, 600 feet (180 m.) head. The principal reason why this runner could not be used with a head of 600 feet is that it would be structurally weak for that purpose. In the same way it is readily seen that a runner with K = 75 would not be suited for the high head work. On the other hand, a runner designed for a high head wheel with K = 20 could be used on a lower head, but in all probability would not be so used for many reasons.

(To be continued.)

THE BUILDING OF BREAKWATERS.

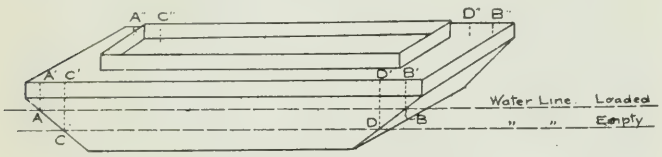
In a discussion of Mr. H. F. Alexander's paper on the "Building of Breakwaters at Lake Erie Ports," presented recently to the American Society of Engineering Contractors, Mr Howard J. Cole presents some interesting remarks. An abstract of his discussion presented to the society is given below.

Owing to the fact that rubble mound breakwaters are the most easily built and cheapest, and can be readily repaired after settlement or damage by storm, this type of construction is quite generally used.

The subject is of special interest owing to the activity in harbor improvements caused by the approaching completion of the Panama Canal. This activity is particularly noticeable on the Pacific Coast of South America, where the governments, with great foresight, are making strenuous efforts to increase their harbor and port facilities to provide for the trade that is sure to follow the opening of that canal.

Some of these governments have already completed the preparations for considerable work of this nature, and most of the plans call for breakwaters of the rubble mound type, with some modifications to fit conditions of each port Sometimes the rubble is topped with monolithic concrete block of 30 tons weight.

In the case of the Manzanillo breakwater, the rubble was obtained at a quarry twenty miles away from the work and cost the owner "in situ" $6.30 per metric ton. In a breakwater at Bar Harbor, Maine, that has been under construction, at intervals, since 1889, the stone, thus far, has cost the U.S. Government slightly over $1.00 per ton. These are in both instances contractor's prices, and include the actual cost and his profit.



Displacement Diagram.

Naturally, the cost of handling, production, etc., will vary according to the situation and with the method employed. If the quarry is handy to the shore, and barges can be loaded easily, a floating equipment will handle the material to the low water line about as cheaply as any other, but above that elevation other methods are better under most circumstances.

In the large works where it was necessary to convey the rubble to some distance, the work was largely carried out in a manner similar to the method of building a railroad fill, viz., by means of a temporary trestle.

On some work, where the writer was engaged, the materials (stone and sand) were delivered on deck scows and the displacement obtained in the following manner:

The exact dimensions of the scow were measured by steel tape and the point A' plumbed up from A, similarly B', B" and A" were obtained, and the distance A' B', A" B", A' A" and B' B" likewise measured by steel tape; the depths A A' and B B' and corresponding depths on the other side of the boat were carefully measured by a graduated rule and noted on a sketch of the boat. When the latter was empty the point C' was plumbed up from C, D' from D, and again on the further side, and the four dimensions corresponding to the loaded measurements recorded. From a comparison of the depths (light and loaded), and with the complete measurements taken, the displacement was computed as hereafter shown.

The length A' B' and A' A", and the other two corresponding measurements were obtained direct on the scow deck, and the depths were obtained by taking the difference between the readings loaded and light and the displacement thus figured.

By averaging the lengths A' B' and A" B" and multiplying by the width A' A", also averaging the lengths C' D' and C" D" and multiplying by the width C' C" and multiplying the average of these two by an average of the differences between the load lines (C' C—A' A, etc.,) at the four corners, one obtains the cubical feet of displacement, which multiplied by 62.5 and divided by 2,000, gives the displacement in net tons and is expressed in figures thus:

$$\frac{\left\{\frac{A'B' + A''B''}{2} \times A'A''\right\} \times \left\{\frac{C'D' + C''D''}{2} \times C'C''\right\}}{2} \times \frac{(C'C - A'A) + (D'D - B'B) + (D''D - B''B) + (C''C + A''A)}{4} \times \frac{62.5}{2,000} = \text{Displacement in tons}$$

which can be expressed in a somewhat simpler manner:

$$\frac{\left\{\begin{matrix}\text{Area of boat}\\ \text{on loaded water lines}\end{matrix}\right\} \times \left\{\begin{matrix}\text{Area of boat}\\ \text{on light water lines}\end{matrix}\right\}}{2} \times \left\{\begin{matrix}\text{distance}\\ \text{between the}\\ \text{two planes}\end{matrix}\right\} \times \frac{62.5}{2,000} = \text{Displacement in tons.}$$

SEWAGE DISPOSAL.

A new municipal enterprise which, it is expected, will have far reaching effects on the problem of sewage disposal is to be inaugurated at Bradford, England, where new machinery for extracting marketable produce from the city's sewage is being put into operation.

Last year, the corporation made a profit of $150,000 from the grease recovered from the sewage, and it is anticipated that at the new works at Esholt, the annual profit will be raised to $250,000. The total sales of these products up to last year reached $500,000.

Besides grease, a market has been found for the pressed cake which remains after the grease has been recovered, and large quantities of this have been exported to be used as fertilizers in France, South America and other countries. The cake has even been in demand as fuel during the recent coal strike and has been used as such in local factories.

Material reductions are made in the freight rates on the Temiskaming and Northern Ontario Railway in a schedule which will take effect on May 20th. The rates are equalized over the system so as to conform with the standard mileage tariff for Eastern Canada, and both for local traffic and through shipments charges are considerably lower.

The revision of existing grades and surveys for the double tracking of the Canadian Pacific Railway main line between Vancouver and Calgary, a distance of over 600 miles, is now under way. The work is in charge of F. F. Busteed, former general superintendent of the British Columbia division, who has established headquarters at Kamloops. Actual double tracking between this city and Port Hammond is now in progress.

The Canadian Engineer

ESTABLISHED 1893.

ISSUED WEEKLY in the interests of the CIVIL, MECHANICAL, STRUCTURAL, ELECTRICAL, MARINE AND MINING ENGINEER, THE SURVEYOR, THE MANUFACTURER, AND THE CONTRACTOR.

THE LATE JUDGE MABEE.

The death of Judge Mabee is a severe blow to the country. Natural ability and wide judicial experience placed him in an exceptional position for filling the chairmanship of the Dominion Board of Railway Commissioners, and during the past four years he has filled this difficult office as few men could.

The office of chairman of this Board is one which demands executive and administrative, as well as judicial powers. The Board was created in 1903 for the purpose of allowing of quick decisions without the hampering and restricting procedure of the courts. To be successful in operation the chairman of the Board must be a man of rare tact, quick judgment, administrative power, and forceful character. This in no mean measure had Judge Mabee. As a result, the Railway Commission has attained a strength and dignity, and its jurisdiction has been enlarged, until the work entailed is most wearing on the chairman.

Judge Mabee's death will be most deeply regretted both by the public and by the railways, to both of whom he was eminently fair, and by whom he was universally admired.

THE ENGINEER AND THE CONTRACTOR.

It is now generally accepted by the engineering profession that to secure the best results in the construction of any work there must be a cordial spirit of co-operation between the engineer and the contractor. The engineer's attitude towards the contractor will be reflected in the finished work. In a recent paper Mr. Charles T. Main, consulting engineer, of Boston, gives expression to certain opinions of what he thinks should be the attitude of the engineer. Mr. Main says:—

> "Reliable contractors are honest, and intend to live up to the plans and specifications. No contractor should be expected to give any more than is called for by the plans and specifications. Some contractors estimate low in the expectation of being able to get by with something inferior to what is called for. All men are human, and most are careless, and for these reasons it is essential to have as much inspection on a job as is necessary to see that the intent of the plans and specifications is carried out.
>
> "This work of inspection and of interpretation of plans and specifications should be done with the exercise of a good deal of judgment, with a mind open to the interests of both the owner and contractor, with clearness and firmness. In many cases where claims are made by the contractors, it is due to the fact that they are not familiar with the plans and specifications. In many cases, however, there may be a conflict or a chance of more than one interpretation to be put on them. In the decision of all of these questions the engineer should assume a judicial attitude and render his decision with fairness to all parties interested. His decision may not be satisfactory to either party, but it must be clear in his own mind that he has done right thing to all.
>
> "No one can see more clearly than he all sides of these questions and reach a proper decision. Sometimes that decision may not reflect any credit upon his own work, but it should be

met fearlessly, if the fault lies in the preparation of the plans and specifications.

"Care should be exercised in the preparation of specifications, so that they will describe the class of work and grade of materials which are intended and expected with clearness and conciseness. A better class of work should not be called for than is required for a particular purpose, nor should it be called for with the idea that something inferior will be obtained which will pass. Just what is desired should be called for in the specifications and demanded by the inspector on the work.

"The attitude of the inspector, or better, the resident engineer, should be one of assistance rather than of criticism."

If the above is accepted as a basis for the guidance of the engineer in his dealings with the contractor, there is no question that much good will result to both sides, and, while we feel that conditions are improving steadily, still there remain many ways in which by a conciliatory attitude the mutual relations of the two parties can be improved.

REFORESTATION AND THE FLOW OF STREAMS.

A number of factors enter into the question of the flow of streams, among which may be named precipitation, rainfall and snowfall; the extent and contour of the drainage area, nature of the ground and condition of the soil; condition of the surface (forested or clear), and the presence of storage reservoirs, either natural or artificial, in the stream. The whole question of river regulation has been given little attention in Canada, although it is one of considerable importance to the economic development of the country. It is generally believed that forest growth on the head waters of a stream tend to afford more uniform flow, for with the ground cleared the water quickly gets to the streams and flows away, with the consequent result of floods at certain times of the year and low water at other times.

While it is believed that the forests have a more or less great effect in equalizing the flow, there has been little accurate data to justify any statement on the subject. A bulletin was issued recently by the University of Wisconsin which deals with the flow of streams and the factors that modify it. This bulletin, while dealing primarily with Wisconsin conditions, is of considerable interest to Canadians.

Professor Mead, who had charge of the work of preparing the bulletin, draws the following conclusions, which are applicable more particularly to our conditions. He states that if forests have any effect on stream flow that can be assigned a practical value, such effects must be manifest by an actual change in the conditions of flow when deforestation occurs, but that in general the cutting of timber in Wisconsin has had no material effect, either favorable or adverse, on the high water, mean water, or low water flow of the stream, or on the regularity of such flow; that if any effects on stream flow have resulted from deforestation, they have been entirely counteracted and obscured by the drainage of marshes, the clearing of farm lands, the second growth of timber and brush, or other similar occurrences, and that in so far as all evidence examined is concerned, there is nothing to show that the planting of forests in Wisconsin would in any way add to or take away from the quantity or regularity of stream flow or decrease of flood heights.

These results, as authoritative data, show that in general little benefit can be expected from reforestation for the regulation of our streams. The construction of storage reservoirs appears to be the logical step for any system having for its aim the equalization of the flow of our streams. A good deal of emphasis has been heretofore placed upon the theoretical advantages to be gained from reforestation, and the studies of Professor Mead will undoubtedly do much to dispel false assumptions and to direct investigation of the subject along the right lines.

CONCRETE BLOCKS IN NEW YORK.

The following specifications were recently adopted for concrete block in Greater New York:

Hollow concrete building blocks may be used for buildings not more than three stories nor more than 36 ft. in height, under the following conditions:

No hollow concrete blocks shall be used unless made of the following composition: One part Portland cement, and not more than five parts of clean, coarse, sharp sand and gravel, or a mixture of at least one part of Portland cement and not more than five parts of crushed trap rock or other suitable aggregate approved by the superintendent of buildings. The aggregate shall be of such fineness as to pass through a one-half inch ring and be free from dirt or other injurious matter, and Portland cement shall be a true Portland and be up to the standard requirements set by this bureau.

All concrete blocks shall be cast true and square, and be of uniform shape and thickness when laid in courses. No such blocks shall be used until complete and satisfactory tests have been made by the manufacturer under the direction of the superintendent of buildings, and until an approval for the use of such blocks has been obtained.

No blocks shall be approved that do not at the age of 28 days develop a compressive strength of at least 1,500 lbs. per sq. in. of net section.

In no cases shall the hollow spaces of the concrete block exceed 33⅓ per cent. of the cross-section of the block. The thickness of walls or webs of such blocks shall not be less than one-fourth of the height of the blocks but in no case less than 1½ inches.

The thickness of walls for any buildings where hollow concrete blocks are used shall not be less than is required by the building code for brick walls. All such walls shall be laid in Portland cement mortar. All outside walls below grade must be filled in solid. No walls composed of hollow concrete blocks shall be loaded in excess of 100 lbs. per sq. in. of the gross section of the wall—that is, no deduction being made for hollow spaces in figuring the area.

Where beams or girders rest on such walls, suitable templates of iron, steel, or stone shall be provided under their ends, or the blocks under them shall be solid. Concrete lintels spanning an opening over 3 ft. 6 in. wide shall be reinforced by steel bars.

Every block must have stamped thereon the name of the manufacturer or the manufacturer's mark.

All walls of hollow concrete blocks, and beams used in same, must be anchored in accordance with Sections 41 and 60 of the building code.

EFFECTIVE STRESS IN BELTS.

In a recent issue of Zeits. des Vereines deutscher Ingenieure appears an account of tests on the limits of effective stress in belts of various materials. An abstract of the article appears in the April Journal of the American Society of Mechanical Engineers. Such tests require a large expenditure of time because overloading of a belt can be discovered only from the appearance of a permanent elongation, and an identical elongation is also found in a new belt which has not yet reached its state of resistance. Since, however, several hours are required for a belt to reach that state, there is always a danger in short tests with new belts of taking phenomena of the state of resistance for those of overload.

Tests of Link Belts.—The tests were made on two link belts of equal width, but unequal thickness, made up of links pressed out of specially prepared fibre, and provided with leather rims. The tests have shown that at a speed of 15 m (say 50 ft.) per sec., the total stress on the tight side of the belt must not exceed 30 kg per cm (166 ft. per in.) of width of belt, but at higher speeds may go as high as 35 kg per cm (193 lb. per in.) of width of belt. Link belts have been introduced because they combined the strength of double with the flexibility of single belts, and gave strong belts which could be used on pulleys of small diameter. These tests have shown that for speeds up to 20 m (65 ft.) per sec. link belts are far superior not only to single, but even to double, leather belts, but at higher speeds the centrifugal tension in the heavy link belt decreases the allowable useful load very materially, and at speeds over 30 m (98 ft.) per sec. link belts cannot be economically used at all.

Tests of Leather Belts.—For speeds up to 15 m (50 ft.) per sec. the total stress in the tight side of the belt did not exceed 23 kg per cm (say 126 lb. per in.) of the width of the belt, while for speed of 30 m (98 ft.) per sec. the total useful tension rose to 26 kg per cm (143 lb. per in) of width of belt.

Americans often assert that belts which are turned out with the hair side to the pulley last longer than when turned with the flesh side to the pulley, as is usual in Germany. Tests made by the author have shown that in belts turned with the hair side to the pulley: (a) the tension ratio, or ratio between the tension on the tight side and that on the loose side hardly exceeds 2, while in belts running with the flesh side to the pulley it can exceed 3; (b) the highest allowable tension is more than 3 kg per cm (12.6 lb. per in.) less than in the case of belts with the flesh side toward the pulley; the speed cannot be made more than 30 m (98 ft.) per sec., against 50 m (164 ft.) with belts with the flesh side toward the pulley. This shows that it is in every respect disadvantageous to let the belt run with the hair side toward the pulley. A belt running in that way probably wears out sooner because, as was pointed out by C. O. Gehrkens, such curvature reverses the way in which the hide grew on the animal.

Tests of High-Speed Belting.—A double cemented leather belt, 45 mm (1.8 in.) wide, stood very well a total tension on the tight side of 67.1 kg per cm (370 lb. per in.), at 60 m (196 ft.) per sec., and broke only when the tension rose to 95.9 kg per cm (say 530 lb. per in.). The allowable useful stress kn can be deduced from the formula

$$kn = (kT - kf) \times \tfrac{3}{4}$$

where kT is the total stress on the tight side, and kf the centrifugal tension.

Tests on Belt Fastenings.—In the tests with woven belts it was found that, as the speed of the belt transmission increased, the allowable useful stress diminished owing to the influence of the belt fastening, which at speeds from 25 to 30 m (81 to 98 ft.) per sec. caused such vibration and uncertainty of run that it proved to be impossible to exceed the speed of 30 m (98 ft.) per sec. The influence of the fastening is due to the following causes: (a) through the centre of gravity of the fastening describing on the pulley a semi-circle, an additional centrifugal tension is developed equal to

$$k'f = \frac{G}{bl} \cdot \frac{v^2}{g}$$

this additional centrifugal tension is thus a function of $\frac{G}{bl}$, or weight of unit area of the fastening, and that indicates the advisability of arranging the fastening in such a way that its weight be distributed over as large an area of the belt as possible; (b) the rotation of the fastening in coming on and off the pulley produces in it a moment of torsion which in its turn produces in the belt an additional centrifugal tension. This tension becomes negligible if the fastening is made of flexible steel bands, softer steel bands lasting longer than hard ones.

A REINFORCED CONCRETE INFILTRATION WELL AND PUMPING PLANT.*

By Frederick N. Hatch, Jun. Am. Soc. C.E.

In this paper will be given a brief description of the design, equipment, and construction of a pumping station recently constructed for the Chesapeake and Ohio Railway at Silver Grove, Ky., as a part of the terminal improvements carried out by the company with which the writer is connected.

It was estimated that the ultimate quantity of water which would be required to supply the terminal would not exceed 1,000,000 gal. per 24 hours, and that the demand would be at a fairly uniform rate throughout that period. As the terminal is near the bank of the Ohio River, water was to be obtained from that stream and delivered to two 100,000-gal. tanks on towers 45 ft. high.

The Ohio River at this point is subject to an extreme variation of about 69 ft. between low and high stages, and it was necessary to design a plant which would operate satisfactorily at any stage. It was also desirable that the plant should be as nearly automatic in its operation as possible, as it would have to be about 700 ft. from the nearest shop building.

Test borings, made at several points on the river bank, showed that the top soil is underlaid by sand and gravel, and that the river bed is in the same formation. With this in mind, it was decided to sink a well on the bank and provide openings in it so that it would receive water by infiltration from the river through the intervening sand and gravel. It was expected that water obtained in this way would not contain much suspended earthly matter, though the Ohio is a turbid stream during high-water stages.

The sounding taken at the point at which the well was finally located showed the different strata to be as follows, the elevation given being that of the top of each stratum:

* Paper presented May 1st, 1912, to American Society of Civil Engineers.

	Elevation.
Extreme high water in the river	407.3
Surface of ground, loam and sand	376.0
Loam and clay	361.0
Gravel, with some sand	354.0
Sand, with some gravel	343.0
Extreme low water in the river	338.1
Fine white sand	330.0
Bed-rock	291.0

The bottom floor was fixed at Elevation 328.0, or 10 ft. lower than extreme low water, and the motor floor is above the highest stage of water.

The pumping requirements and conditions are as follows:

Minimum capacity	700 gal. per min.
Maximum static head	127 ft.
Minimum " "	66 ft.
Discharge	through 1,000 ft. of 8-in. cast-iron pipe.

The pumps are to be driven by electric motors taking 3-phase, 60-cycle, 440-volt current; the motors are to be controlled automatically by the water level in the tanks; and all equipment is to be in duplicate.

Constant-speed, centrifugal pumps were selected on account of the great variation of effective head, and the fact that pumps of this type have a low starting torque, which is favorable to automatically-controlled, alternating-current, motor drive. The pumps are 5-in., constant-speed (1,140 rev. per min.), top-suction, vertical, single-stage, centrifugal turbines, manufactured by Henry R. Worthington. At low-water stages each has a capacity of 700 gal. per min. against a total head of 142 ft., and requires 43.5 motor h.p. to operate it; at high water, against a total head of 104 ft., the discharge is 1,150 gal. per min., and the required horsepower is 50.5.

Each pump is driven by a Westinghouse 50-h.p. squirrel-cage type, induction motor, mounted on a cast-iron base on the motor-room floor. Each motor is controlled by a separate automatic starter, the two starters being mounted on one board and connected to the power line so that only one motor can be operated at a time. The solenoid switches of the starters are actuated by single-phase current controlled by a float-switch on one of the tanks. In order to prevent too frequent operation of the pumps, the float-switch is arranged so that it does not close until the water level has fallen to a point 5 ft. below the top of the tanks.

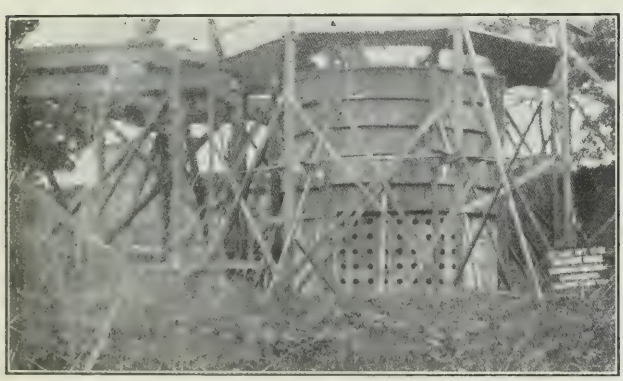

Fig. 1.—Lower Part of Shaft Before Sinking, Showing Openings Through Which Water is Admitted.

The shafts connecting the pumps to the motors are held in alignment by guide-bearings, adjustable in all directions, attached to rigid, built-up beams. The entire weight of the shaft and any possible unbalanced thrust of the pump impeller is carried by a marine-type thrust-bearing, mounted just below each motor. Flexible couplings prevent any of the weight of the main shaft from being transmitted to the motor rotor shaft and its separate thrust-bearing.

The entire shell of the well, including the motor-house and roof, is of reinforced concrete. The shell was designed to be sunk as an open caisson below the ground level.

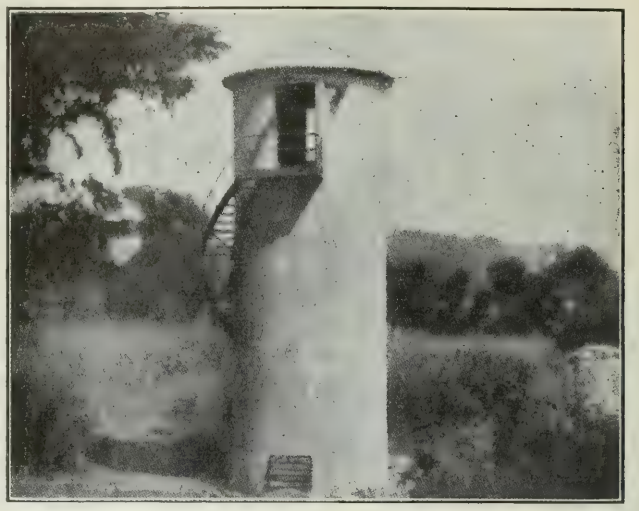

Fig. 2.—Completed Infiltration Well.

Sufficient reinforcement was provided to prevent the walls from pulling apart in case the upper part of the shaft should be held by the forms or the friction of the earth, while the power part was free. Besides providing for the erection stresses, the walls and bottom were reinforced to withstand any possible unbalanced earth or water pressure.

The motor-room floor was designed for a live load of 400 lb. per sq. ft. plus the concentrated loads of the motors, shafts, etc.

Water is admitted to the well through 63 openings formed by pieces of 5-in., wrought-iron pipe extending through the walls of the well below the low-water line. The aggregate area of the openings is 8.75 sq. ft. These openings are shown on Fig. 1, the photograph having been taken just after the sinking of the shaft began. Inside the well these holes are enclosed by a steel-plate chamber designed to withstand the unbalanced hydraulic pressure on the inlet side during high-water periods, with the inside of the shaft dry. A 24-in. sluice-gate, to control the inflow of water, is mounted on the side of this chamber. The gate is operated by a geared stand on the motor-room floor. To insure the proper spacing of the inlet chamber anchor-bolts, and also to provide an even joint surface, a steel angle companion flange was made with the flange of the chamber as a template. This companion flange was built into the concrete wall, and the anchor-bolts, which had enlarged ends tapped inside for 1-in. tap-bolts, were held in place by tap-bolts extending through the forms. A sheet-lead gasket was inserted between the companion flange and the flange of the chamber.

There is an opening, enclosed by a pipe railing, in the motor-room floor to give access to the lower part of the well, and steel ladders extend from bottom to top, inside.

The built-up beams for supporting the shaft guide bearings were designed for rigidity, and were set in pockets left in the walls of the well during construction. As the cover-plate serves as a walkway for inspecting the guide bearings, each beam has a pipe railing along one side of it.

A single I-beam, suspended above the motor-room floor and the hatchway, and extending as a cantilever beyond the entrance platform, serves as a track for a 4,000-lb. trolley provided to handle any of the heavy equipment.

An outside spiral steel stairway gives access to the head-house. The brackets supporting the stairway were built into pockets in the outside of the walls of the shaft.

The estimated weight of the well complete with its equipment is 530 tons, while the gross buoyancy during extreme high water, with no water inside the well, is about 465 tons, leaving a margin of stability of 65 tons, if the friction between the earth and the lower part of the shell is neglected.

Fig. 2 is a view of the completed well as seen from the land side. Fig. 3 shows the general design of the well with the equipment; but minor details have been omitted, and, to avoid confusion, some parts have been shown out of the true section.

Construction.—After leveling off the site, the steel-plate, cutting shoe was set up, and the forms were erected over it. The forms were of ⅞-in. sheathing nailed to waling pieces cut to radius. Those for the outside of the wall were supported by the posts of the working platform, and were held together, in sections, by steel bands arranged so that they could be loosened to allow the wall to slip through them. The inside forms were hung from cantilever brackets on the working platform, and were held in position by removable cross-braces, a construction which permitted the free use of the entire interior during the periods when excavating was being done.

The reinforcing rods were put in position, and a section of concrete about 5 ft. high was carefully placed and allowed to set. The forms were then loosened, and the material was excavated from the inside by a ¾-yd. orange-peel bucket handled by a derrick. As the excavation progressed the wall gradually sank. The operations of placing concrete and excavating were carried on alternately until the foot of the shaft reached its final position. The shell sank very freely through the earth, and it became necessary to provide some means of checking its descent at the proper place. This was accomplished by forming a concrete collar, integral with the wall, just above the ground level, and then taking a part of the load off the cutting shoe by blocking between this collar and the ground surface. The collar was designed to carry a large part of the suspended weight of the well if necessary. By the use of the collar the sinking of the wall was stopped at the proper place, and there was no settlement while the sand was being removed from beneath the cutting shoe.

Before the shaft reached the water level, the intake chamber was bolted in position and the sluice-gate was attached to it. When the excavation reached the water level, a large pulsometer pump was used to remove part of the water and fine sand.

As the flow of water through the open bottom of the shaft was too great to be handled by pumps, a diver was sent down to level off the bottom of the excavation and place the reinforcement for the rough bottom of the well; he also distributed the concrete for this bottom. After allowing the concrete to harden, the well was pumped dry and the finished bottom was put in.

The upper part of the shaft was constructed by raising the forms by stages as the wall was completed, and no conditions unusual to the construction of similar structures were encountered.

After the shaft was completed, the steel, guide-bearing supports were placed, leveled up, and grouted in place. Great care was required in getting the supports and bearings perfectly level and plumb, so that the vertical shafts would run smoothly.

This pumping plant has been in operation for some time, and it has been found, as anticipated, that the water reaching the interior of the well is free from suspended earthly matter, although at times the river has been quite turbid. At no time has there been a shortage of water in the well, even when the pump was running at its rated capacity and the river stage was very low.

The construction of that part of the well below the ground level was accomplished in 18 working days, and the entire part above ground in 6 working days.

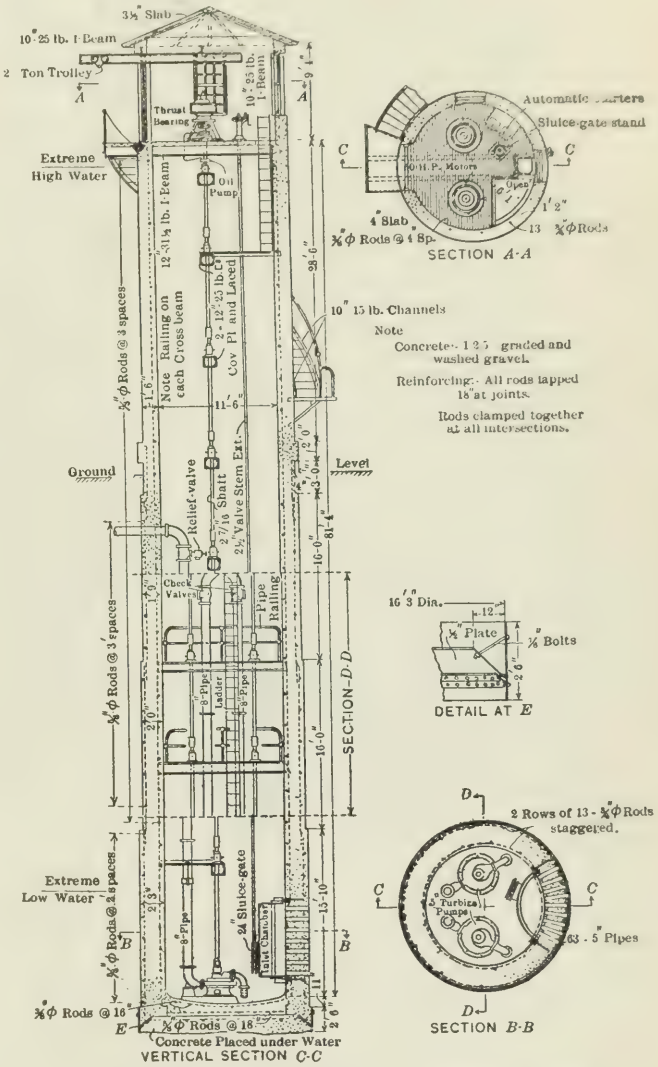

Fig. 3.—Reinforced Concrete Infiltration Well.

As the construction of the well was only a small part of the work done at Silver Grove, and as the entire job has not been closed up, only approximate costs can be given The figures show the actual costs of construction, and do not include engineering, drafting, and other overhead charges.

Grading and excavating	370 cu. yd. at	$1.65
All concrete, including reinforcement, material	280 " " "	3.15
All concrete, including reinforcement, labor	280 " " "	3.85
All forms, material, and labor	at	$2.85 per cu. yd.
All steelwork, fabricated and otherwise, material	28,000 lb. at	$0.052
All steelwork, fabricated and otherwise, labor	28,000 " "	0.022

(Costs of steel include painting.)

All equipment, piping, wiring, etc., in place.....$6,200

This pumping station was designed, constructed, and equipped by Westinghouse, Church, Kerr and Company, of New York.

EMBANKMENTS AND FOUNDATIONS—TORONTO-SUDBURY BRANCH C. P. R.*

By A. C. Oxley, S. Can. Soc. C.E.

The Toronto-Sudbury Branch of the C.P.R. was constructed in the years 1905-1909, and, as the standards were of a very high type, they may contain some points of interest. No curves over four degrees were allowed, and the grades were limited to 3/10 per cent. compensated. These grades were successfully maintained, with the exception of a pusher grade of 8/10 per cent., for some miles near Tottenham, mile 37. This difficulty will eventually be obviated when traffic demands it by the substitution for freight purposes of eight miles of 3/10 per cent. track for the present three miles of 8/10 per cent. Velocity grades were allowed within the limits of 10 and 30 miles per hour for freight trains.

The intention of the company was to insure a thoroughly solid roadbed, rather than to keep initial expenses at a minimum, and, as the greater part of its 225 miles ran through a rock and muskeg country, there was frequently some difficulty in attaining this result. This article, however, will deal only with the district between miles 22 and 182, north from West Toronto, from Bolton to Byng Inlet,

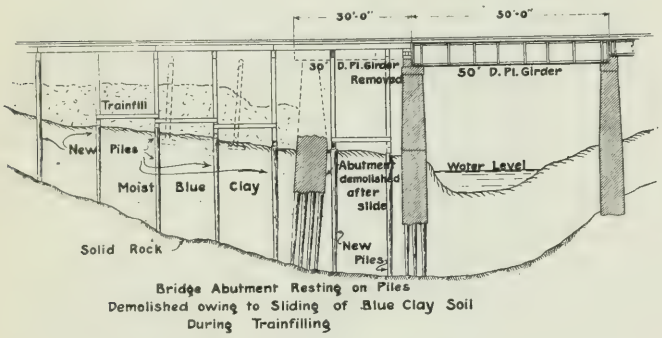

Fig. 1.

as this was the part with which the writer became personally familiar during his four years' experience on the work.

The line may be divided into two sections, viz., the earth district and the rock district, the first running from mile 22 to 92, and the second north from mile 92 to mile 248.

On the south, or earth section, little difficulty was encountered either with foundations or embankments. Eventually all streams and gulleys will be bridged either by steel viaducts, or by concrete arches and embankments, but at the time a number of permanent timber trestles were built, several of them containing an average of 500,000 F.B.M. The bents of these trestles rested on piles driven to an average depth of 20 feet or more, and the only settlement that has occurred has been on the ends of the trestles, where the bents rested on mud sills on the made embankment.

A curious instance of an over-refinement of engineering occurred at the Nottawasaga River trestle. The trestle is about 700 feet long, with a maximum height of 110 ft., and is located on the short tangent between two reverse curves. The trestle itself has an average elevation of 10 or 15 ft. below the general track elevation in the immediate vicinity. This is overcome by the use of 2,000 ft. of velocity grade of 6 or 7/10 per cent., resulting in a high rate of speed for the consolidated locomotive that passes over it. This will easily be remedied, however, when the trestle is replaced by a steel viaduct, either by building the viaduct higher or by slightly reducing the little summits adjacent to it. The curves also may be somewhat lessened by turning the new viaduct in a direction more nearly parallel with the tangents.

In the earth section water openings were either concrete or glazed tile pipes for small drainage areas, with concrete arches for larger ones. The pipes, on the whole, were very satisfactory, except that in a number of instances insufficient allowance had been made for their becoming reduced in area by being partially filled with water-washed sand; it was, therefore, necessary, under these circumstances, to replace 18 or 24-inch pipes with 4 ft. arches. The rule was to "camber" as high as the drop would allow, and the adjustment of the soil under the embankment was usually sufficient to take out quite a large curve, as "shrinkage" seemed to be due not only to the settling of the deposited embankment, but chiefly to the sagging of even firm clay in such a way as to cause a low spot in a pipe laid flat, and the consequent tendency of the pipe to clog. The culverts were the standard 1905 and 1906 types of concrete arches made in 20 ft. sections, to allow settlement. Piles were used in exceptional cases, a row under each side, but the general practice was to divert the stream far enough to secure firm soil.

In the rock country, practically all openings of eight feet or less were built up of the excavated rock and laid without mortar, those over four feet in width being made double, with the top constructed of flat-lintel stones. These proved entirely satisfactory in the great majority of cases, as they were laid on solid rock a little to one side of the original stream.

We will now proceed to deal with the rock section, discussing particular points in the order of their mileage from the south end. At mile 102, near Buckskin, a rock embankment about 10 ft. high crossed a fairly dry muskeg, in which the rock was about 50 or 60 ft. down. No cross-waying was ever permitted, as the intention was to have the rock embankment cut its way through the thin mattress of the dry surface of the muskeg; in this case the rock remained on the surface for about a year, and then gave way during train-filling. Some time was spent in filling it, as its depth allowed the train gravel to move sideways, but eventually bottom was reached after 3,000 Hart car loads of gravel had been placed in it. The only real objection to its sinking, when it did, was that the gravel used was high-grade surface gravel, which had to be hauled about 40 miles, as tracklaying had not then proceeded far enough to reach the more northerly, and thus more convenient, sand pits.

The only midway divisional point was at Muskoka, mile 126 from West Toronto. As this point was in the rock district the grading for it was rather heavy, the finished yard occupying an area, apart from the main passing siding, of about 3,000 x 300 ft., much of which was solid rock that had to be lowered about ten feet. Water was obtained from the nearby Stewart Lake, but, as it is not allowable to pollute the Muskoka waters, the sewers had to drain into the swamp on the other side of the track.

The general mode of procedure through the rock country was to make the rock cut only about a third of the embankment, as this quantity of rock would have sufficient weight to cut its way vertically through the mattress, and as soon as bottom was reached the remainder could be made by train-filling. The efficiency of this method of forcing the sink-holes through is shown by the fact that, train-filling once completed, the percentage of derailments has been at least as low on this new roadbed as on that of sections twenty years old or more. This brings up an important question. If the intention is to have the weight of the rock cut its way through the mattress, and as it is only when

* Paper read before Canadian Society of Civil Engineers.

it has done so and reached solid bottom that the earth filling becomes really effective, would it not be advisable, in some instances, before placing the rock fill, to cut right through the mattress parallel to the centre line, for instance, in the case of a thirty-foot embankment, to cut two longitudinal ditches forty feet apart, and thus allow that whole section to sink vertically without deforming the surface at the side? Almost every case of deformation is caused by the sand or gravel floating sideways, and it does not become solid for some time.

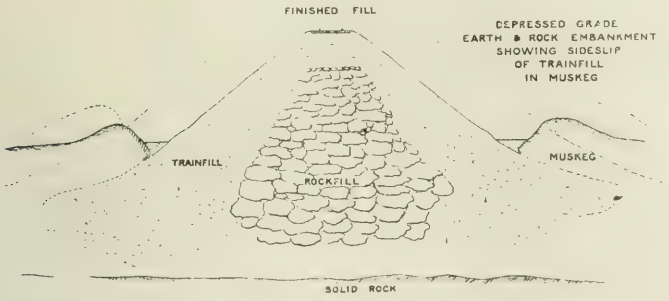

Fig. 2.

Depressed temporary grades of 3 per cent. were allowed. In many cases small hillocks of rock were cut away to allow the temporary grades to descend to the centre of the larger gulleys.

At mile 124, during train-filling, a low rock embankment, while carrying an engine, gave way suddenly, and the engine sank with such force as to shear the nuts in the track for a distance of 1,000 ft. or more. Between miles 112 and 142 a number of embankments were train-filled from temporary trestles, and little trouble was experienced, although in many cases it was found necessary to lower the level of adjacent small lakes in order to give more solid bearing to the toes of the slopes.

At Richmond Lake, mile 101, south from Romford, the lake level was about fifty or sixty feet below the level of the track. A rock embankment rested firmly on the solid rock below, but was not carried up to grade, a trestle being used above water level. The water would probably seep through the rock fill, but, in the event of its not doing so, it would easily flow through the trestle at high water. At mile 76, south from Romford, occurred one of the heaviest train-fills of the line, the depressed grade being no less than twenty-five feet at a maximum below the final grade, and, as it was necessary in filling to cover the toes of a rock embankment up to thirty feet in height, at least a quarter of a million yards of earth must have been used in this one-half mile of fill.

At mile 75.5, south from Romford, a temporary trestle beside a lake had been train-filled, but the water had apparently dissolved the embankment and caused lateral slipping. The lake was small, and the lowering of its level about four feet left the toe dry and firm.

In many instances, where a comparatively dry muskeg was to be crossed, provision was made for thickening the dry supporting mattress by ditching and lowering the level of the water table. This was generally effective, provided there was solid soil in the mattress, but not invariably. At mile 70.5 from Romford, the track crossed a muskeg about two thousand feet long and from twenty to forty feet deep, with an embankment when completed about four feet high. A drainage ditch was dug, leaving the water table only about four feet below the level of the surface soil. The track crept very badly and made "sun kinks," elevations taken during the passage of a train showing track undulations of one or two-tenths. The track was made safe for traffic and prevented from creeping by the substitution of 14-ft. bridge ties; later it was diverted to a side hill of solid rock and made thoroughly solid.

At mile 66:7, south, in order to make secure a muskeg, which for its length gave considerable trouble, a depressed grade was built, with a rock embankment about 10 ft. high, the lowest point of which was a maximum of about 20 ft. below the intended finished grade. In this case, although soundings showed a depth of 50 ft. or more to bed-rock, the weight of the rock embankment was not in itself sufficient to slice through the surface mattress. This was somwhat unfortunate, as it was always found that, although earth alone would eventually reach a firm foundation, yet, owing to its specific gravity being so low, it had a great tendency when placed by train-filling, to move horizontally rather than vertically, causing the mattress to bulge upwards for some distance out from the toes of the slope.

The writer was not present until the completion of the filling of this sink-hole but, although it had a length of only 600 ft. and had to be lifted to a height of 20 ft. above the depressed grade, a fill of 30,000 yards had raised it only 3 ft. Fortunately, by the use of spreaders, the embankment while sinking retained a good surface and alignment, and no difficulty was experienced in running passenger trains over this temporary velocity grade.

The next large fill occurred at the crossing of the Magnetawan River, the valley of which was about 3,000 ft. wide. With the exception of three girder spans this valley was crossed by a timber trestle about 40 ft. high. In this case the length of the trestle helped to reduce the unit cost of filling, as it was possible to fill from temporary grades placed on each side of the trestle, and thus leave the main line open for traffic.

It might now be interesting to mention a few of the bridges, with reference to foundations. On this 160 mile section, with two exceptions, there were no steel bridges larger than plate girders; the exceptions were at the Severn River, where there was a 200 ft. through Pratt truss, and at Parry Sound, where there was a viaduct 1,700 ft. in length. The largest span consisted of two Howe deck trusses of 165 ft. span. In the earth district all concrete was carried below frost line and rested on piles; while in the rock country the piers in almost every case rested directly on the rock itself.

During the construction of the Parry Sound viaduct a simple method was adopted to eliminate delay. The track was paralleled at the points by the C. N. O. Railway, and running rights, or rather haulage rights, were given by that railway over a four-mile section through Parry Sound. In this way it was possible to lay some twenty miles of steel north of the Sound during the construction of the viaduct, at the same time leaving the bridge contractors a mile or more of blind main line for bridge yard purposes. The only difficulty occurred at one of the abutments at the South Nascoutyong River. In this case the abutment was carried to a depth of 10 or 15 ft. below the surface of the ground, and piles were then driven to bed-rock, about 20 ft. further. Back of the abutment was a temporary trestle about 30 ft. high resting on mud sills, the soil being an alluvial clay, which was kept moist by the presence of a stream less than 100 ft. away. No trouble was experienced with the abutment until train-filling had proceeded for some time on the temporary trestle, when the earth filling caused a flow of the clay sub-soil, and, although the bases of the piles remained in their places on bed-rock, the flowing of the clay caused the abutment to tilt forward, necessitating its demolishment. No further attempt was then made to fill the embankment,

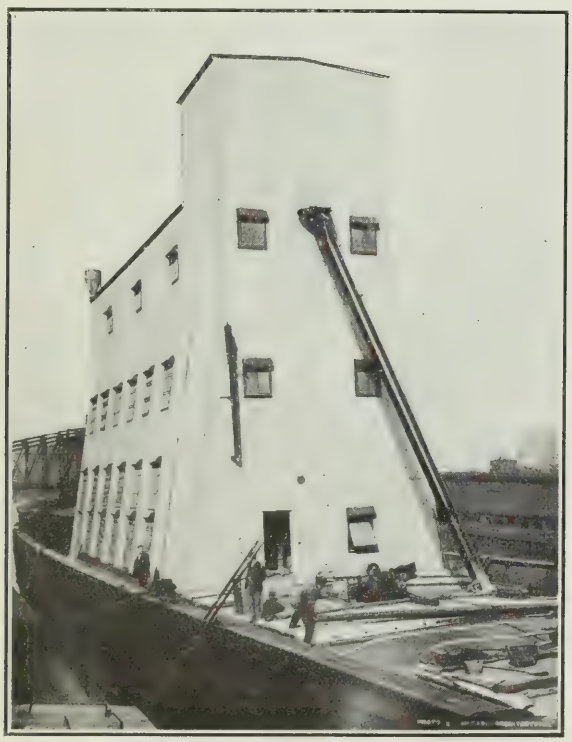
but piles were driven and a trestle constructed, both in place of the temporary trestle, and also between the abutment and the next pier, the new trestle replacing a short girder span.

In this case, even if the pier had been constructed just as it was, had piles for the temporary trestle been driven at once, the clay might possibly have been so firmly anchored that there would have been little, if any, horizontal movement.

ARMOUR FLOATING DRIER PLANT.

The Armour Grain Company has just completed probably the largest grain drier there is in the world at an investment of not far from $200,000. To build the drier they purchased and used the lake steamer "Helena," which has been in the grain-carrying trade on the Great Lakes. The length of the vessel is 310 feet and its beam 34 feet. It has a carrying capacity of about 125,000 bushels of grain. Upon this boat an Ellis drier has been constructed with a drying capacity in the neighborhood of 75,000 bushels in twenty-four hours.

The machinery is so constructed that grain can be put aboard the drier from any elevator, and, after drying, the steamer "Helena," with her own steam, can go to any point and discharge into any vessel, elevator or railroad car with her own machinery. In this manner there is avoided the necessity of unloading at an elevator having a marine leg.



Armour Floating Drier Plant.

In addition to the grain-drier constructed aboard the steamer "Helena," there is considerable storage capacity, which has been constructed with hopper bottom bins with conveyers, which will take the grain from this storage into the drying machinery. After being dried the grain can either be discharged from the steamer "Helena" or put into the storage bins aboard the boat itself. The whole plant has been constructed under plans and patents furnished by the Ellis Drier Company of Chicago.

The equipment aboard the boat is complete in every way, including electric lights, a laboratory furnished with moisture testers and other devices needed in a grain-drying plant.

A brief description of the drier equipment will prove interesting at this point. The driers are arranged in a battery formation, two six-unit machines to a battery. Directly in line with the driers are located the coolers, composed of two six-unit machines. Each battery is 28 ft. 4 in. in height by 10 ft. 2 in. in width. Both driers and coolers are constructed entirely of steel. Connected with each drier are steam coils of a special design for the utilization of exhaust steam. In connection with the coils are two automatic feed pumps and receivers, which take care of all water of condensation and pump it directly back to the boilers. As an extra precaution in case of breakdown these pumps are cross-connected.

Heated air to the driers is delivered by "Sirrocco" fans, each fan capable of delivering 110,400 cubic feet of air per minute. Air to the coolers is delivereed by a fan of the same type. While delivering this tremendous volume of air the fans are practically noiseless. All three fans are driven by an angle compound centre crank type engine, built by the American Engine Company, of Bound Brook, N.J. Steam is furnished by two Scotch marine boilers. This plant has been in operation about five weeks.

STANDARD SEWER SPECIFICATIONS.*

By E. J. Fort and A. J. Provost, Jr., New York City.

No standard specification for sewer construction which has been generally recognized or adopted as such, has up to the present time been produced and the specifications in use by even the largest and most important municipalities, vary widely in many of their most important provisions. Difference in local conditions would, no doubt, warrant special provisions in regard to some of the more important details, but there would seem to be little reason why, in the most important particulars, standard requirements may not be applicable.

Materials of construction of acceptable quality are usually available.

The functions to be performed by the finished structures are substantially the same, and if the structures are designed to be permanent, as economy and expediency would generally require, the standards of excellence in the materials and workmanship employed, may well be uniform.

Specifications for sewers of extraordinary size and special design will generally require addenda supplementing the standard specifications to meet the requirements in each particular case, while for pipe and masonry sewers of ordinary size, standard forms should ordinarily suffice.

It is the opinion of your committee that the complete instrument designed to govern every detail in the execution of contracts for sewer construction, should contain:

First—**A notice to Intending Bidders.**

Such a notice should state clearly:

(a) Time and place at which bids will be received.

(b) Location and extent of the work to be bid for.

(c) Time allowed for the execution of the contract.

(d) **Amount of security required.**

(e) Manner in which the bid shall be presented and its contents.

(f) Engineer's estimate of cost.

(g) General cautions in regard to preparation of bid and execution of work.

(h) Other information for the assistance of the contractor in the preparation of his bid.

*Abstract of a report to the American Society of Municipal Improvements.

Second—**Contract or Agreement Proper.**

The contract form should contain in addition to the language of the agreement, bonds, official signatures and acknowledgements of the same, and official designations of the fund from which the expense is to be met.

(a) A certified copy of the official action granting authority to execute such a contract.

(b) A description of the parties to the contract and the officials or employees under whose supervision it is to be executed.

(c) A statement covering in detail all the work to be done and the prices bid for same.

(d) A definition of the authority and duties of the engineer and assistants in control of the work as the representatives of the city or party of the first part.

(e) A definition of the rights of the contracting authority in determining the time of commencement, supervision of work, methods of precedure, force to be employed, etc.

(f) A definition of the contractors' obligations in executing the work in accordance with specification requirements and the directions of the supervising authority, and in maintaining the same, in the protection of property from damage, the payment for labor and materials, the completion within contract time, manner and time of payment, liquidated damages for delay beyond the contract time, etc.

(g) Method of procedure in modifying the contract.

(h) Clauses relating to liens, claims, damages, guarantees, assignments, etc.

(i) Enumeration of the provisions of laws and ordinances especially applicable to municipal contract work which must be observed.

(j) Other clauses of special or local application.

Third—**Specifications.**

Following a general description of the work embraced in the contract and the limits within which it is to be done, the limits within which the lines may be located, manner and times of fixing grades by the engineer, the manner in which measurements shall be made, etc., the specifications should include:

(A) A description in detail of all labor performed both preliminary and subsequent to the emplacement of the sewer structure, and the manner of its performance.

(a1) Excavation of Trenches.

1. Dimensions for various sizes of sewers and lengths to be opened at one time.
2. Shoring and bracing.
3. Pumping and baling.
4. Foundations, their preparation to receive the sewer.
5. Disposition of excavated material.
6. Provisions for the maintenance of street traffic while work is under way.
7. Removal of pavements and disposition of paving material.
8. Protection and support of other structures.

(a2) Refilling of Trenches.

1. Character of material to be used especially about sewer.
2. Manner of placing, ramming, flooding, etc.
3. Disposition of surplus, deficiency, how met.

(a3) Embankment.

1. Dimensions.
2. Character of materials, how placed and compacted.
3. Provisions for traffic through intersecting streets.

(a4) Replacing of Street Surfaces.

1. Unpaved streets. Surface to be restored; maintenance period.
2. Pavements, curbs and sidewalks out of guarantee; how restored; maintenance period.
3. Pavements, etc., under guarantee; how restored.

(B) A description in detail of all materials to be employed; their quality as shown by standard tests, and their proper manipulation to produce the finished structure.

(b1) Cement and Mortar.

1. Cement, quality, standard tests to be met.
   Cement, how delivered and stored.
   Cement, measurement of volume.
2. Mortar, measurement and proportions of ingredients.
   Method of mixing.
   Character of sand.
   Amount of water.

(b2) Concrete.

1. Size and character of stone or gravel.
2. Size and uniformity of sand grains.
3. Proportions of ingredients to be used in mixture.
4. Methods of mixing, placing and surfacing.
5. Molds and forms.

(b3) Brick Masonry.

1. Quality and size of bricks to be used.
2. Manner in which they are to be laid and protected from injury. (Inverts, arches, haunch walls, manholes and catch basins, spurs and branches.)

(b4) Stone Masonry.

1. Quality and dimensions of stones. Rubble, ashlar and dry masonry, coping stones, basin heads, etc.
2. How laid to produce finished walls and structures.

(b5) Steel and Iron.

1. Rods for reinforcement, quality, dimensions and tests.
2. Structural shapes, quality, dimensions and tests.
3. Expanded metal, wire mesh, etc.
4. How placed in the finished structure.
5. Spikes used in platforms, grillages, cribs, etc., quality, dimensions, etc.
6. Cast iron.
   Quality and tests.
   Conformity to place.

(b6) Sewer Pipe.

Specification for pipe sewers and sewer pipe is to be in accordance with recommendations of Committee C4 of the American Society for Testing Materials, appointed to report upon "Standard Specifications and Tests for Clay and Cement Sewer Pipe." The work of that committee is not yet completed. Its last annual report, June, 1911, is referred to. .

(b7) Pile and Timber Foundations.

1. Bearing Piles.
   a. Kinds and quality of timber.
   b. Dimensions.
   c. How driven.
   d. How measured and paid for.
2. Foundation timber.
   a. Kinds and quality of timber.
   b. Dimensions as shown on plan.
   c. How laid and secured.
3. Sheathing and Bracing Timber.
   Manner of Placing
   a. To remain in the work.
      Kind, quality, dimensions, etc.
   b. To be withdrawn.
      Kind, quality, dimensions, etc.

(b8) Sewer Connections.

1. Manner and time of connecting house drains.
2. Connections intersected to be re-connected.
3. Flow of old sewer—how cared for.
4. Method of making all connections.

(b9) House Connection Drains.

1. Spur pipe to receive house connection drains. Spacing and size. How laid.

2. Standpipes on deep sewers.

3. Cast-iron pipe for house connection drains, where necessary, how laid, quality, etc.

(b10) Manholes.

1. Concrete, brick.
   How built, dimensions, etc.

2. Manhole heads and covers.
   Standard plan.
   Weights, dimensions, etc.
   Quality of iron.
   Inspection.

(b11) Sewer Basins or Inlets.

1. Standard plan.

2. Excavation, dimensions, how made.

3. Heads and gratings or pans.

4. Traps.

5. Culverts, dimensions, how laid and connected to same, etc.

6. Restoration of curb, sidewalk and pavement after construction.

FLOUR MILLING AND MILL ENGINEERING.

At a meeting of the American Society of Mechanical Engineers held in Philadelphia, March 30, 1912, a paper was presented by B. W. Dedrick, instructor of milling and mill engineering, Pennsylvania State College, State College, Pa., on Flour Milling and Mill Engineering. An abstract of the paper is given below:

The ancient builder of mills was called the millwright, and, even up to comparatively modern times, was the only person capable of designing, building, and placing machinery and planning buildings for their accommodation, not only of flour mills, but factories or whatever machinery was employed.

The modern flour mill building does not depart radically from other buildings designed for the reception and operation of heavy machinery, but the height of building and floors is given more consideration. Mill buildings are usually carried up three, four, five or more stories above the basement. It is necessary and better economy to have sufficient height in order to place certain machines one above the other, so as to take advantage of the force of gravity in the handling of stock. In designing mill buildings, the engineer must also take into consideration the great weight to be supported, not only of the heavy and numerous machines required and their driving connectors, spouts ad bins, but of the grain and flour that is kept within the building. Besides, in the modern mill nearly all machines used are rapidly revolving, and if improperly placed or balanced, are particularly hard on a building, causing a perceptible weaving motion or tremor. The floors have to be of proper height to give sufficient pitch or incline to spouts, for if the spout is too flat or of insufficient pitch, the flour or other material will not run down, but choke or clog. The flour mill building, especially on the grinding and bolting floors, should be well lighted by a sufficient number of windows in day time, and electric or other good light at night, for it is necessary frequently to inspect the flour and other stock, and a good steady and bright light is absolutely essential to detect the extremely close shades in the color of flour, and to compare it with the standard samples.

Practically the first step of the wheat in the mill is in the separators, of which there are usually two: the receiving, that rough cleans the grain as it comes into the mill, taking out straws, wheat heads, sticks, oats, seeds and other trash; and the mill separator, that handles the wheat, cleaned almost entirely of foreign matter, making a closer and finer separation of the wheat, taking out any remaining oats, white caps, joints and seeds left over by the receiving separator. The light and imperfect wheat is drawn out by air current. From the separators the thoroughly cleaned wheat goes to the scourer which has a cylinder or series of blades of beaters revolving very rapidly, from 500 to 700 revolutions. These beaters throw the grain against the "case" which may be simply of heavy woven wire, the mesh or openings being small enough to prevent even the smallest berry from passing through, but allowing pieces of bran, chit or seed to be forced through, to settle in the hopper below, or to be drawn into the fan.

The effect of the beaters throwing the wheat against the rough casing at varying angles is to scour off the beards, exteriors dirt and, in case of severe scouring, the outside cuticle or woody covering, all this being forced through the openings of the case, with the beaters acting as blowing fans. In both cases of the separator and scourer, the wheat is subjected to a current of air or suction at the receiving end and again on leaving the machine; this takes out the lighter wheat and remaining dust. On their passage to the fan, the heavier grains are arrested when they get into the tips where the expanding air loses some of its force, and cannot carry them farther, so they fall of their own weight into what is called "the screening tips." In some mills wheat that contains a great deal of cockle seed is passed through a cockle-cylinder which removes seed more perfectly. Mills that use wheat containing a good deal of smut or contaminated by smut, wash the wheat in machines for that purpose, after which it is dried and again scoured and tempered before going to the rolls.

A modern roll called a "double stand" consists of two pairs, one on each side. If each pair handles different material as they do in smaller mills, a partition below the rolls practically makes each a distinct pair.

The rolls are carried on bearings, which are rigid for one roll and movable or free for the other, allowing this roll to be adjusted closer to or further apart from the other roll according to the fineness desired to break or crush the stock passing between the rolls.

The arms of the movable roll are pivoted below on eccentric bearings, one on each side of the roll frame. The tramming or bringing the rolls into level is accomplished by means of turning this eccentric bolt, and then locked by a nut, but the arm is allowed to move or swing freely as in adjusting the rolls or spreading them apart, by the lever, when shutting down or when the roll runs empty. The arm at the top carries a recess which contains a heavy coil spring, which bears against the inner closed end, and against the wheel at the outer end. The rod passing through is the adjusting or lighter, corresponding to that of the millstone. At the outer end is the hand wheel used to compress the spring and thus stiffen or increase the tension. The inner hand wheel is the adjustor. By turning the wheel left or right, or forward on the threaded rod, it permits the rolls to close up; turning it in the opposite direction, spreads the rolls apart. Passing through the centre under the feeder housing is a small shaft to which is attached a lever. There are two pairs of eccentrics on each end, to which are attached the adjusting rods by their yokes. The movement of the lever in one direction throws both the movable rolls from their mates simultaneously at both ends, and vice versa brings them back to position.

Each pair of rolls has a fast and slow roll. In order to grind or crush with effect, there must be more or less of a

rending or tearing action, and for this reason the rolls are given "differentials" in speed, the most common differentials used being 2½ to 1 for break rolls on wheat, to 1½ to 1¼ to 1 on the middling reduction rolls, which are smooth almost without exception, though very finely corrugated, or scratch rolls are sometimes used on the first clean middlings.

There are several types of bolters or sifters. The hexagon or six-sided reel is the oldest type of bolter still used, but its action in bolting is rather harsh. The round reel dresser is gentler in action, and like the hexagon, is slow in running, 30 revolutions being the mean. The centrifugal reel is used only on very soft, flaky material, for its disintegrating effect. The gyrating type of sifter is altogether considered to be the best and most gentle of all. The action of the gyrating sieves is to compel the stock to travel spirally on the surface of the flat sieve and on top of the silk, so as to bring the lighter, fluffier and impure parts on top of the travelling stream and hold them there until they tail off, the purer going through the cloth. Various means or devices are used to keep the meshes of the cloth open.

From there the wheat goes to purifiers. In the old flat grinding process all the flour possible was made at one and the first grinding. This system was very simple, consisting of a rolling screen, a smutter, a pair of burrs, one or two long reels, and a couple of elevators. Some middling or semolinas were made, but of such a character and containing so much fine bran or germs that when these middlings were reground on stone and bolted, it made an inferior flour as compared with the first, or superfine, produced in the grind of the wheat itself. The invention of a successful middlings purifier changed all that. From seeking to grind low, making no middlings, or as little as possible, it now became the object to grind higher, cut the bran as little, and make as much middlings as possible. The miller reduced the feed on the stone by half, bestowed more skill and patience in dressing the burr, giving smoother surfaces and grinding higher and cooler with a millstone; he thus produced middlings that after being purified and then ground separately on stones and bolted, made flour superior to the "first" or "clear" flour produced from the grinding of the wheat itself. This flour produced from the purified middlings was called "New Process" or "Patent" flour.

The different grades of middlings, after being purified, are crushed on the smooth rolls and then sent to the different sections of the sifter and sometimes to reels, as in the last roll reduction. With each reduction and subsequent separation of bolting, there is a certain amount of flour sifted out, and as a natural consequence there is an increased proportion of impurities to be handled on the next reduction and separation, so that the tendency is for the flour to be less white and clear, and partially to counteract this tendency it is necessary to have the cloths finer and finer. After certain reductions the tailings may be of such a nature as not to require further handling, and are sent direct to feed as finished, while those containing any floury parts are again reduced and sifted, the final results being flour, bran and shorts.

The paper contained also a detailed discussion of the capacity of machines and weights, and a description of the model mill to be built at Pennsylvania State College, State College, Pa., to give students the practical part of milling, and for experimental purposes in the way of testing the different kinds of wheat, to ascertain the bread making qualities of the flour; baking and chemical tests of flour and grain, and experimentation with various machines as to efficiency, power absorbed, etc.

BELTING INFORMATION.

The following, along with other valuable information, is taken from a catalogue and handbook published by the Fitz Water Wheel Co., manufacturers of the well-known I-X-L Overshoot Water Wheel, Hanover, Pa.:—

Rule for Calculating Length of Belting before Pulleys are Placed in Position.

Add together the diameter of the two pulleys and multiply the sum by 3.14159. To half of the result thus obtained add twice the distance from centre of one pulley (or shaft) to centre of the other pulley (or shaft).

Example.—Given the distance between centres of pulleys, 28 feet 8 inches; diameter of pulleys, 52 inches and 46 inches. What is length of belt?

52 + 46 = 98 × 3.14159 = 307.87 inches.
307.8 ÷ 2 = 153.98 inches ÷ 12 = 12.83 feet.
Centres 28 8-12 feet × 2 = 57.33 "

Answer 70⅙ feet.

Tightners.—The tightening pulley is applied to the belt to increase its adhesion to the pulley, and, as this is to fall first on the smaller pulley, it is usual to place it on the slack side of the belt near this pulley in order to increase the area of contact as well as adhesion. It also increases the friction of driving in proportion to the thrusting of the belt from the line of its natural curvature.

Correspondence and Discussion Invited

UTILIZATION OF SLAG HEAT.*

It has long been realized that in the operation of blast furnaces the usual practice of tapping the slag into ladles, and removing it in a molten state to the slag-tip, is extremely wasteful of heat. It has the further disadvantage of occupying all the available land in the vicinity of the furnaces and rendering it useless; whilst disposing of the slag in this manner becomes gradually more and more costly as the tips get higher and further away, and the surrounding land becomes more valuable for the housing of workmen, etc. This difficulty has been met to a small extent in some works by the introduction of slag-brick-making machinery, slag wool or silicate cotton plant, and crushing and granulating plant for cement or manure, but in all these processes the enormous quantity of heat contained in the slag is entirely wasted.

Various attempts have been made to utilize the heat of slag for raising steam, but owing to the rapidity with which slag scales over and ceases to part freely with its heat when exposed in trays passing through boiler flues, and the losses in transmission of heat through plates, only a very small portion of the total heat can be actually imparted to

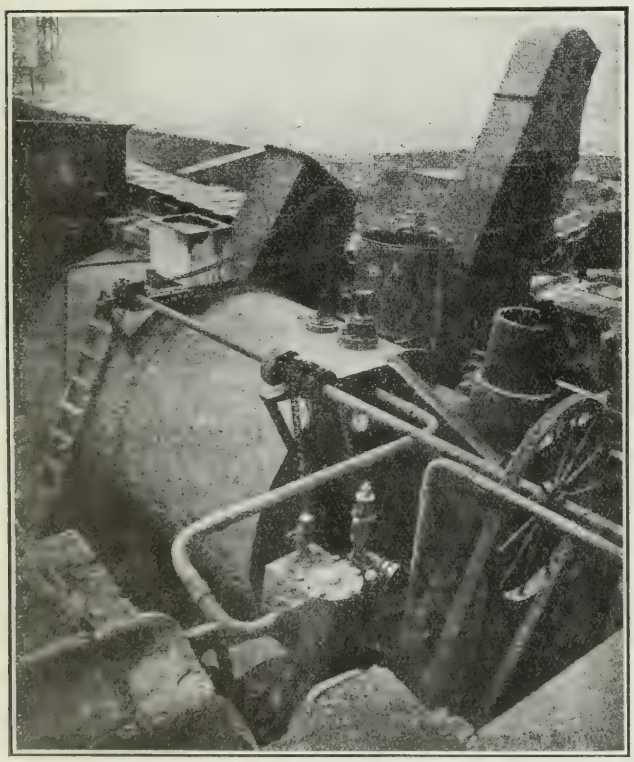

Fig. 1.—Experimental Plant for Utilization of Slag Heat.

the water in an ordinary boiler. In other designs where it has been attempted to take the slag hot or molten into the water, the formation of acids, due to the presence of air, has rendered the steam unfit for use for the generation of power, owing to the destructive effect of the acid on the boiler-plates and machinery; while the admission of air to the boiler makes condensing impracticable.

In the plant described and illustrated below, practically the whole of the heat in the slag is effectively imparted to the water in the boiler, and the exclusion of air from the boiler is a feature which not only prevents the formation of acid, but also allows of the steam generated being economically used in a low-pressure turbine, as the highest degree

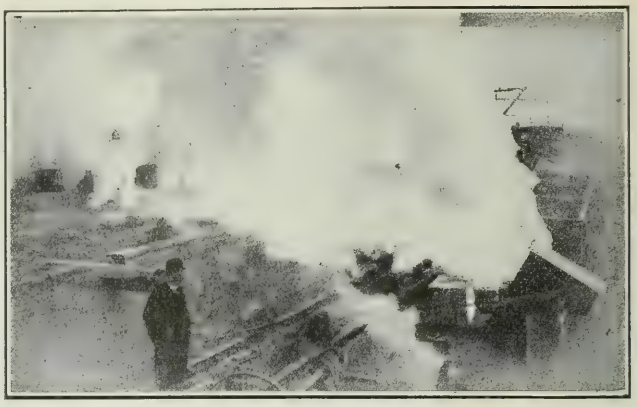

Fig. 2.—Plant in Operation.

of vacuum can be maintained at the condenser. The system is based on the Vautin patent, developed by Messrs. Slag Power, Limited, of 638 Salisbury House, London Wall, E.C. In dealing with slag from copper furnaces, the steam generated was found, on analysis, to be well suited for use in low-pressure steam turbines, and it was decided to ascertain whether the slag from blast furnaces could also be handled under the patent.

Fig. 1 illustrates the temporary experimental plant installed for this purpose at the ironworks of Sir B. Samuelson & Company, Limited, of Middlesbrough, and modified as required, and Fig. 2 shows the same plant at work, blowing steam to atmosphere through a 13-inch gate valve fully open, the pressure in the boiler being about 1 lb. above atmospheric pressure.

Chemical analyses have shown that no trace of sulphuric acid, or, in fact, of any kind, can be detected in the steam when condensed; that the amount of sulphuretted hydrogen is not sufficient to be harmful to the blades of a turbine, if made of sound and suitable metal; that the steam, though almost instantaneously generated, is superheated about 70 deg. Fahr., and that the quantity of steam generated from a furnace producing 1,800 tons of slag per week could safely be relied upon to develop 500 kilowatts of electric current per hour, with an expenditure of 6 h.p. for operating the plant.

The following figures may be taken as fairly representative of the quantities of the principal ingredients in a large number of samples of the granulated slag and condensed steam analyzed from time to time.

Slag.—Silica, 28.5 per cent.; alumina, 19 per cent.; lime, 36.4 per cent;. sulphur, 1.12 per cent.; iron, from 0.7 to 2.5 per cent.

Steam (in grains per gallon).—Chlorine, 0.4; total sulphur, 10; sulphuretted hydrogen, 3; acid, 0.

The corrosion of the shell of the boiler, after alternately working and being exposed to atmospheric influences for several months, is quite normal and uniform, showing no sign of pitting. A quantity of clean mild-steel drillings was placed in a sample of the condensed steam, and at the end of a fortnight the water was drained off and found, on test, to contain no trace of iron.

*Iron and Coal Trades Review.

In the "Vautin" system of working, air is excluded entirely from the boiler by means of a slag trap at the inlet and a head of water at the outlet. The elevator casing is made small in area, and the cold feed water is admitted at this point, to minimize the loss by evaporation, and the elevator push-plates are perforated to allow water to drain back into the boiler. Usually the most convenient arrangement is to install a separate boiler close to each furnace at the end of the slag road, the molten slag being led by a trough into the trap, and as it flows from same it is granulated in the steam space by a flat jet of the hot boiler water, circulated by a small centrifugal pump.

The elevator for removing the granulated slag is a combination of the push-plate and tray types, the trays being above the slag as it is pushed along the bottom of the boiler, to prevent any light material floating again after having been skimmed from the surface of the water. The granulated slag is removed from the end of boiler furthest away from the inlet, where it is taken up to a suitable height for discharging into a small storage hopper or direct into trucks.

About three minutes after slag is admitted, a cold boiler is steaming at full capacity, and the steam is led by a baffle-plate past the incoming slag to take up superheat. The working pressure is 1 to 1½ lbs. per sq. in. above atmospheric pressure (say 16 lbs. absolute), and the traps and elevator casings are designed so that no air is admitted unless the pressure is allowed to drop below 13½ lbs. per sq. in. absolute. The steam from each boiler is piped to the steam main, which supplies a low-pressure condensing steam turbine driving an electric generator.

Each boiler is fitted with two slag traps (one of which is a stand-by), and either of them can be emptied and made air-tight in a few minutes. There is a large body of slag in a molten state under the inlet to the boiler to prevent chilling, but prickers are also provided in case "nosing" is necessary. The traps are fitted with tapping holes and hinged bottoms for removal of the "skull" formed after a stoppage, the bottom doors being counter-balanced so that one man can easily operate them. The plate forming the bridge of the trap is quickly renewable and is a small, simple and cheap casting. The slag inlet to the boiler, which protects the boiler-plate, is also small and cheap, and is reversible before renewal.

The boiler illustrated was cylindrical, 8 ft. in diameter by 12 ft. long, but a flat-bottomed boiler about 6 ft. 6 in. wide and 10 ft. high is preferred. The power required to operate the granulating pump and the elevator is only about 1 per cent. of the power generated.

RAIL OUTPUT IN AMERICA, 1911.

According to statistics collected by the American Iron and Steel Association, and published in their "Bulletin," the production of all kinds of rails in the United States in 1911 amounted to 2,822,790 tons, as against 3,636,031 tons in 1910, a decrease of 813,241 tons, or over 22.3 per cent. Rails rolled from purchased blooms, crop ends, and "seconds," and re-rolled and renewed steel rails are included. Included in the total for 1911 are 205,409 tons of girder and high T steel rails for electric and street railways. The maximum production of all kinds of rails was reached in 1906, when 3,977,887 tons were rolled.

Bessemer Steel Rails.—The production of Bessemer steel rails in 1911 amounted to 1,138,633 tons, as against 1,884,442 tons in 1910, a decrease of 745,809 tons, or over 39.5 per cent. Of the total in 1911, 1,053,420 tons were rolled by makers of domestic ingots and 85,213 tons by companies which did not operate Bessemer converters. Included in the total by makers of ingots are 19,379 tons of re-rolled rails.

Open-Hearth Steel Rails.—The production of open-hearth steel rails in 1911 was 1,676,923 tons, as against 1,751,359 tons in 1910, a decrease of 74,436 tons, or over 4.2 per cent. Almost all the open-hearth rails in 1911 were rolled from basic steel and all were rolled by producers of open-hearth ingots.

Miscellaneous Rails.—A total of 7,234 tons of miscellaneous rails was rolled in 1911, including 234 tons of iron rails, 462 tons of rails rolled from electric steel, and 6,538 tons of re-rolled steel rails which the makers were unable to classify as Bessemer or open-hearth rails. Of the total production of steel rails in 1911, 2,708,795 tons were rolled from ingots made by the makers and 113,761 tons were rolled from purchased ingots or blooms, crop ends, "seconds," or renewed or re-rolled rails.

Weight of Rails.—The following table gives the production of all kinds of rails in 1911, according to the weight of the rails per yard. Girder and high T rails for street and electric railways are included.

Kind of rails.	Under 45 pounds. Tons.	45 pounds and less than 85 Tons.	85 pounds and over Tons.	Total. Tons.
Bessemer rails ...	111,231	606,300	421,102	1,138,633
Open-hearth rails.	100,755	461,387	1,114,781	1,676,923
Miscellaneous	6,772	9	453	7,234
Total in 1911 ..	218,758	1,067,696	1,536,336	2,822,790
Total in 1910 ..	260,709	1,275,339	2,099,983	3,636,031
Total in 1909 ..	255,726	1,024,856	1,743,263	3,023,845
Total in 1908 ..	183,869	687,632	1,049,514	1,921,015
Total in 1907 ..	295,838	1,569,985	1,767,831	3,633,654

OIL-FIRED OPEN-HEARTH FURNACE.*

E. Richarme.

The principal dimensions of the oil-fired furnace at Tsaritsyne are: Length of hearth, 14 ft.; width at the level of the burners, 6¼ ft.; mean height, 3½ ft.; air flue, 44 by 6 in.; slope, 30 degrees; slope of burners, 14 degrees. The bed is formed of two layers of magnesite bricks (the upper one laid on edge) covered with a layer of granular magnesite mixed with 25 per cent. of slag. The end wall is of magnesite bricks, and the front wall of magnesite brick below, and silica brick above. The injectors through which the petroleum residuum used as fuel is forced into the furnace, are arranged one on each side, and are sloped at a low angle to prevent the direct impact of the jets on the surface of the metal bath. The arch is made of large silica blocks.

The furnace was started working in April, 1907, and in November, after running 1,129 charges, was stopped for cleaning out the slag boxes. The end walls and door arches were repaired at a cost of 756 roubles (about £80), but the arch of the furnace and the chequer-work of the air chambers were still in good condition; in fact, both these portions of the plant lasted out a run of 1,694 charges before part of the arch collapsed. Examination then showed extensive corrosion of the arch, and both ends were corroded at the springings of the arch, the flues being also

* Revue de Metallurgie.

more or less eaten away. In the air chambers the upper layers of silica bricks were discovered to be fused, and about half the cells in the next layer were choked up, the rest of the chamber being in fairly good condition. The total cost of repairing these defective parts of the furnace and air chambers amounted to 2,113 roubles (£220). Up to the time of these repairs the furnace had been run for 591 shifts, or 1,694 charges (each of an average of 264 poods, or 4¼ tons), the net production per 24 hours being 1,432 poods (14 tons). The consumption of charging material included: Hematite pig, 172,651 poods (2,785 tons); scrap, 270,126 poods (4,357 tons); 80 per cent. ferro-manganese, 1,783 poods (29 tons); 50 per cent. ferro-silicon, 1,115 poods (18 tons); or 445,675 poods (7,189 tons) in all. To this must be added: Ore, 10,172 poods (164 tons); flux, 26,177 poods (422 tons); magnesite and dolomite, 4,921 poods (80 tons); and fuel, 57,998 poods (935 tons). The total production amounted to: Ingots, 387,053 poods (6,245 tns); molten steel for castings, 36,212 poods (584 tons); and waste in runners, gates, etc., 5,079 poods (82 tons), a grand total of 428,344 poods (6,911 tons).

Since that time the furnace, which has a capacity of about 4 tons, has been run continuously, with a stoppage for repairs once a year after an average run of 1,700 charges, and a mean cost for repairs of 0.7 copeck per pood (11d. per ton) of output. The consumption of fuel is 130 per cent., and since the heating value of this fuel is 11,200 cal., as compared with 7,300 cal. in the case of coal with 11 per cent. of ash, the foregoing consumption corresponds to one of 200 per cent. of coal.

The jet of oil fuel is directed toward the bath of metal at an angle of 14 degrees to the horizontal; a simultaneous examination of flame and furnace arch through smoked glasses shows that the arch is dark in comparison with the flame, and that there is a dark zone between the two; a circumstance which explains the long working life of the arch and also the large number of charges which can be worked in 24 hours. This arrangement of the flame so as to heat by contact with the charge is contrary to the theoretical recommendations of certain metallurgists, namely, that the heat should be reverberated from the arch of the furnace. As a matter of fact, the flame must be kept as far as possible away from the arch and as close as possible to the materials to be heated, in order that the arch may be protected from corrosion and the heating be effected with rapidity and economy.

The seven 20-ton furnaces worked on the same system at Tsaritsyne also act satisfactorily. The charges have the following composition per 1,000 parts of steel produced: Hematite pig 670; scrap iron 360; steel scrap 20; ferro-manganese (80 per cent.) 4, Krivoi-Rog ore 60; rolling-mill cinder 40. The consumption of petroleum for heating and smelting is 150 parts, corresponding to 230 per cent. of coal containing 11 per cent. of ash. All the materials of the charge are put in cold. These 20-ton furnaces run for 1,094 charges before any extensive repairs are needed. The diurnal output is over 60 tons each; that is to say, three charges per 24 hours, on the average of the year's run, with an occasional output of 80 tons, or four charges, per 24 hours.

REPRINT OF PROPERTIES OF METAL.

On page 606, May 2nd issue of *The Canadian Engineer* was printed a table of "Properties of Metals." As this will probably be of considerable use to draughtsmen and designers, we have reprinted the table on heavy mounted paper. Copies may be obtained free by addressing the Book Department, The Canadian Engineer.

GAS CIRCULATION IN ELECTRICAL REDUCTION FURNACES.*

By Jos. W. Richards.

Mr. J. A. Leffler's splendid report on the working of the Trollhättan furnace in the electrical reduction or iron ores, presented at the annual meeting of the Jernkontoret at Stockholm, Sweden, May 31, 1911, occupying over 200 pages of that Society's transactions, brings out more information as to the electrical reduction of iron ores than has ever before been available. The report has been discussed at length before this Society by Mr. T. D. Robertson (Volume XX, page 375), and also by Mr. Otto Frick, in Metallurgical and Chemical Engineering (December, 1911, page 631). A discussion of the results and of the devices employed brings into prominence the question of circulating the gases in such an electric shaft furnace, a device which has been employed by the Aktiebolaget Elektrometall for the last three years. The writer has some reflections to offer upon this subject, which may be preceded by a short discussion of the reasons for the adoption of this circulation.

Reasons for Circulating the Gases.—In the early working of the Domnarfvet furnace, the weakest point was the overheating of the roof of the crucible. To preserve this roof, Messrs. Groenwall, Lindblad and Stalhane conceived the idea of bringing from the top of the furnace some of the waste gases, and injecting them, comparatively cool, into the space beneath the arched roof of the crucible and charge beneath, so as to cool the under surface of the arch and thus preserve it from destruction. Later, some of this cool gas was also employed to pass through the bronze castings, forming jackets through which the electrodes passed, thus cooling them thoroughly and sending into the furnace the heat absorbed from them, instead of losing said heat in cooling water.

Incidentally to the use of cool waste gases, it was found that when these gases were thus returned into the crucible of the furnace, in amount equal or superior to the volume of gases being generated by the reduction of the ore, this additional volume of gas carried out of the crucible into the shaft of the furnace above a considerable amount of heat, thus prolonging upwards the hot zone of the furnace, and increasing considerably the amount of reduction of the ore by CO gas in the shaft of the furnace. Indeed, without this circulation of gases the amount of gases produced by the reduction alone in the crucible was insufficient to heat the shaft of the furnace to any considerable distance, thus rendering the shaft useless as a place of reduction of the ore by ascending gases. The circulation was then pushed to an extreme, such that two-thirds to three-fourths of all the gases passing out at the top of the furnace was returned to the crucible, and thus virtually the same gas passed two or three times through the charge; the effect of this increased circulation was a pronounced economy and advantage, viz., increased heating of the shaft by the carrying upwards into it of surplus heat from the crucible, that is, a better distribution of the crucible heat upwards into the shaft of the furnace, and finally a better ratio of CO_2 to CO in the furnace shaft gases, showing that much reduction of ore has been accomplished by CO gas in the upper part of the furnace, and thus the ultimate goal of better utilization of carbon in the furnace was attained.

The writer is convinced, however, that these advantages are offset by serious disadvantages. The most obvious dis-

*Presented at the recent meeting of the Am. Electro-Chem. Soc.

advantage is that the moisture of the charges and the CO_2 of the flux and the CO_2 gas naturally produced in the furnace are returned in large part to the crucible, and there act upon the unconsumed carbon, by the reactions.

$$CO_2 + C = 2CO$$
$$H_2O + C = H_2 + CO$$

This very materially cools the smelting zone of the furnace, its most vital working part. The constructors and operators of these furnaces have recently introduced dust-catchers to intercept fine dust carried out at the top of the furnace by the gases, and also scrubbers, where the circulating gas is cooled, washed, and made to deposit this excess of water before passing into the crucible of the furnace. This device certainly removes the dust and most of the water of the gases, but cannot remove the CO_2 which it is the aim of the circulating process to increase to as high a percentage as possible and thus economize the carbon of the furnace. It stands to reason, therefore, that the better the circulating system works in facilitating reduction in the furnace, that is, in producing more CO_2 in the gases, the more prejudicial will be the introducing of the gases into the crucible of the furnace produced by the chemical reduction of this CO_2 to CO. Besides, the circulating system is cumbersome and expensive, and soon reaches the maximum of useful effect; in the writer's opinion it is an imperfect solution of the difficulties of the furnace. Considering merely the reduction of the ore by CO gas in the shaft of the furnace, it is a question of temperature and time, and to a lesser extent of the amount of CO gas passing. The reduction in the crucible undoubtedly produces CO gas, which, rising upwards slowly through the charge, will have the very best opportunity of producing the maximum amount of CO_2 if it slowly filters upwards through the shaft and there has ore at a low red heat to act upon. If it were possible to keep the column of ore in the shaft of the furnace at a low red heat it is certain that the CO gas would perform the maximum amount of reduction possible, and pass out one-half or two-thirds converted into CO_2, thus consuming the theoretical minimum amount of carbon for reduction in the furnace. The critical point of this analysis is that the ore in the shaft and furnace cannot be maintained at a red heat by the ascending of the gas naturally produced by reduction of the ore; it is insufficient in amount. It follows that the reduction is facilitated either by maintaining the ore red hot by other means, or by circulating the gases two or three times through the ore, thus keeping the materials in the shaft at the reducing temperature. The latter scheme has been the only one adopted, and has been effective, but the extent of its advantages is largely self-limiting, as has been already explained. It is quite evident that when the amount of gas passing through the furnace is increased two or three times, its velocity is increased two or three times, and therefore it is in contact with the ore only one-half to one-third as long. Theoretically this would mean that there would be no increased reduction by CO, except because of the higher temperature produced in the shaft by the increased volume of circulating gas increasing the velocity of the reduction reaction. The consideration of these circumstances leads to the following proposition.

Modified Working.—The writer thinks that the circulation of the gases should be entirely dispensed with, thus simplifying very greatly the operation of the furnace and regularity of its running. If this were done, means should be provided to preserve the arch of the crucible other than by injection of cool gas beneath it. I believe that the present experience of furnace men in preserving arches, ports and bridges of open-hearth furnaces by means of water-cooled plates embedded in the brick-work can be made to conserve the form of the arch of the crucible satisfactorily, thus dispensing with the necessity of introducing cool gas for this purpose. Then, having gotten away from the circulation of the gas, and the furnace again started in its original path, we can reduce the ore in the crucible by carbon and allow only the CO gas there produced to filter slowly through the charge in the shaft of the furnace.

In order that the ore in the shaft of the furnace may be reduced by gas it will be necessary to adopt other means of keeping the charge in the shaft of the furnace at a temperature above, say, 400° Centigrade. This can be done by means of auxiliary electric energy, and also conceivably by jacketing the shaft and burning the waste furnace gas around it.

I therefore suggest that the material in the shaft of the furnace be heated by the waste gases of the furnace burnt in flues around it, or by electric current passed through it from surface electrodes embedded in the walls of the shaft, at a point near the middle of the shaft, sufficient current being passed through the charge to heat it by its own resistance to a red heat. This will give the up-rising CO gas the maximum opportunity of reducing Fe_2O_3 and attaining equilibrium. In this way I believe that the following reaction can be attained,

$$5Fe_2O_3 + 9C = 6CO_2 + 3CO + 10Fe$$

representing the maximum formation of CO_2 by reduction in a slow current of CO. The above reaction requires only 200 parts of carbon per 1,000 or iron reduced, which is much better than can possibly be attained by the present circulating system.

As above given, the reaction is based upon dispensing with the CO_2 of the limestone; that is, the limestone should be calcined outside of the furnace (which could also be done by waste gas of the furnace itself). This saves carbon by avoiding the evolution of CO_2 from carbonates in the lower part of the furnace, below the zone of reduction by CO gas, but where CO_2 is reduced to CO by solid carbon.

Conclusions.—(1) The arch of the crucible of the furnace should be protected by water-cooled plates, as is common in open-hearth furnaces.

(2) The artificial circulation of the gas in the furnace should be dispensed with.

(3) The limestone flux should be calcined before putting into the furnace.

(4) The shaft of the furnace should be provided with auxiliary heating to maintain its contents at or above 400° Centigrade, to permit of reduction of Fe_2O_3 by the slow current of CO gas.

(5) Under these conditions an amount of carbon equal to one-fifth of the weight of iron produced should be sufficient, producing gas containing two volumes of CO_2 to one of CO.

(6) Eliminating the expense of circulating and purifying the gas, and reducing the amount of fuel required for reduction, would both simplify and cheapen the operation of the furnace.

CORRECTION.

In the April 25th issue of *The Canadian Engineer*, on page 510, an article by Mr. Ed. S. Bryant on "Foresting" was credited to the Boston Society of Civil Engineers. This article was read before the New England Waterworks' Association.

A NEW HYDRAULIC TURBINE.

A description of the hydraulic turbines of the Société anonyme des Ateliers de Construction de Th. Bell et Cie de Kriens (Lucerne, Switzerland), is given in L'Industria. An abstract of the article appears in the April Journal of the American Society of Mechanical Engineers. The turbine is of the Francis type. The regulator is shown in Fig. 1. The oil under pressure is driven from the reservoir B by a pump, driven by the pulley S, to the valve gear V, which communicates with the cylinder chambers C_1 and C_2 by the ducts K_1 and K_2, and with the reservoir B by the duct K_3. The valve gear is regulated by the spring governor R in such a way that the pressure acting on one side of the piston

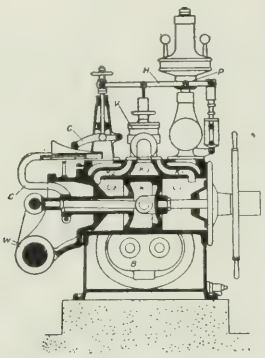

Fig. 1.—Oil Regulator in the Bell Water Turbine.

K varies according to the conditions of work of the turbine, and produces displacements of the piston which are transmitted to the governor spindle. To decrease the stroke of the piston, and to prevent excessive opening and closing of the turbine, the gear rod G is provided to bring the valve into its middle position, so that when the number of revolutions of the turbine is constant, the pump works as if there were no pressure, and it had only to make the oil circulate, thus making the consumption of power very slight.

PERSONALS.

Mr. Murray D. Kennedy has been appointed manager of the Beacon Mines at Elk Lake, Ont.

Mr. Robert Potter, B.Sc., of Fernie, B.C., has been appointed to the position of city engineer of Regina, Sask.

Mr. L. A. Thornton has been appointed to the office of a city commissioner for the municipality of Regina, Sask.

Mr. Arthur B. Lee has received the appointment of secretary-treasurer of the Woodstock Water and Light Commission.

Mr. F. M. Radford, of Sidney, has been appointed assistant to the Commissioner of the Geodetic Surveys of Canada.

Mr. E. F. Bradley, of the Canadian General Electric Company, has been appointed sales-manager of the Canada Wire & Cable Co., Ltd.

Mr. Edward Henry Keating, consulting engineer, and a former city engineer of Toronto, has been elected to the Council of Institution of Civil Engineers of Great Britain.

Mr. Mellis Ferguson, of Stratford, has been appointed city engineer of Guelph, at a salary of $2,000 a year. Mr. Ferguson has been town engineer of Stratford for the past few years.

Mr. H. A. Brazier has been appointed to the position of assistant city engineer for the municipality of London, Ont. Mr. Brazier has been for some time employed in the engineering department of the city of Toronto.

Mr. Carl I. Printz has opened offices in Toronto as a Consulting, designing and inspection engineer. His office address will be 127 Delaware Avenue, He will take over the Ontario business of Messrs. Escher, Wyss & Company.

Mr. R. L. Werry has been appointed secretary-treasurer of the Montreal Builder's Exchange. Up to the present Mr. Werry has been engaged in newspaper work and has had especial opportunities of keeping in touch with interests that will be found of value in his new position.

Mr. R. H. Parsons has been appointed superintendent of the municipal power plant at Edmonton, Alta. Mr. Parsons recently completed a hurried trip across the Atlantic in order that the position should not remain unoccupied long, owing to the resignation of Mr. Huffman.

Mr. Geo. C. MacLennan, S.P.S., '10, has been appointed resident engineer for Messrs. Mitchell & Mitchell, consulting engineers, Toronto, on power development at Minnedosa, Man. Mr. MacLennan has just completed his post-graduate course at the University of Toronto.

Mr. H. T. Routley, O.L.S., D.L.S., of the firm of Routley, Summers & Malcolmson, Haileybury, Ont., was recently elected to the presidency at the Board of Trade at that town. Mr. Routley is engineer for the township of Coleman, which is the richest township in the Dominion.

OBITUARIES.

The list of men, prominent in the public life of Canada, who have been recently called by the hand of death has been added to by the sudden death of **James Pitt Mabee,** late chief commissioner of the Board of Railway Commissioners for the Dominion of Canada.

His death resulted from an attack of appendicitis, and occurred in St. Michael's Hospital, Toronto, on Monday, May 6th, last.

The late Judge Mabee was born in 1859 at Port Rowan in Norfolk county, Ont. He was educated at the Port Rowan High School, and, graduating at the age of eighteen, went into the study of law. He was called to the Bar when but twenty-three years of age, and for five years practised in Listowel. From Listowel the young man moved to Stratford, where he practised for eighteen years. It was from here he began to assume the duties which doubtless hastened his end, and Chairman Mabee proved himself to be capable of the big work before him. To be chairman of a body that has jurisdiction over some twenty-five thousand miles of railway reaching over half a continent was a work which had no parallel in any other country. In this capacity he had to exercise all the powers of analysis that made him a big lawyer and a strong judge; all the patience and tenacity that make a master mind in dealing with evidence. And Chairman Mabee became the biggest unelected public man in Canada.

The deceased leaves a son, Lionel, with the National Trust Company, Toronto, and a daughter, Mabel, at home. Mr. O. H. Mabee, of the Manufacturers' Life Insurance Company, is a brother of the deceased.

The Canadian Pacific Railway have recently lost a valued and trusted official in the person of **Mr. James Oborne.** His death occurred in Vancouver, B.C., on Tuesday, April 30th, from erysipelas. Mr. Oborne was for some time superintendent of this railway at Toronto, but had been recently appointed General Superintendent of the Pacific Division. He was born in Montreal fifty-five years ago and entered the offices of the mechanical superintendent of the Grand Trunk Railway when about fourteen years

old. In 1883 he joined the staff of the Canadian Pacific Railway as chief mechanical clerk. In 1886 Mr. Thomas G. Shaughnessy, then general manager, appointed James Oborne his chief clerk. He held his position for sixteen months. In September, 1887, he was made car accountant, and in 1890 superintendent of car service. In 1892 Mr. Oborne was appointed general fuel agent. Four years later he was made assistant to the vice-president, and his tenure of office continued for three years. Following this office, Mr. Oborne got his first appointment as a division superintendent. He was sent to Winnipeg to supervise the affairs of the division, which then extended from Port Arthur to Laggan, B.C. In 1901 he was transferred to the superintendency of the Atlantic division, with headquarters at St. John, N.B. After two years he was appointed general superintendent of the eastern division, with headquarters at Montreal. Then, in December, 1906, Mr. Oborne was appointed general superintendent of the Ontario division, with headquarters in this city. He held this position until two months ago, when he exchanged the Ontario superintendency for that of the Pacific Coast.

COMING MEETINGS.

AMERICAN RAILWAY ASSOCIATION.—May 15th. Semi-Annual meetlng at New York City. Sec'y, W. F. Allen, 75 Church St., New York.

INTERNATIONAL RAILWAY FUEL ASSOCIATION.—May 22nd-25th. Annual Convention at Chicago, Ill. Secy., D. B. Sebastian, La Salle St. station, Chicago.

FOURTH NATIONAL CONFERENCE ON CITY PLANNING.—May 27th-29th. Meeting, Public Library, Boston, Mass. Sec'y, Flavel Shurtleff, 19 Congress Street, Boston, Mass.

AMERICAN WATER WORKS ASSOCIATION.—June 3rd-8th. Annual Convention at Louisville, Ky. Secy., J. M. Diven, 271 River St., Troy, N.Y.

CANADIAN ELECTRICAL ASSOCIATION.—June 19th-21st. Annual meeting at Ottawa, Ont. Sec'y, T. S. Young, 220 King St. West, Toronto, Ont.

SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION.—June 26th-28th. Annual meeting at Boston, Mass. Sec'y, H. H. Norris, Cornell University, Ithica, N.Y.

ONTARIO MUNICIPAL ASSOCIATION.—Annual convention will be held in the City Hall, Toronto, on June 18th and 19th, 1912. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ont.

CANADIAN PUBLIC HEALTH ASSOCIATION.—Second Annual Meeting to be held in Toronto, Sept. 16, 17 and 18.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE: Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, S. J. Chapleau, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving; Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, C. E. Cartwright; Secretary, W. Alan, Kennedy; Headquarters: McGill University College, Vancouver.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1290.

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydonejack; Meets every first and third Friday of each month, October to April, in University of Manitoba, Winnipeg.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION.—President, Chas. Hopewell, Mayor, Ottawa; Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm. Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, W. Sanford Evans, Mayor of Winnipeg; Hon. Secretary-Treasurer, W. D. Lighthall, K.C., Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, Mayor Mitchell, Calgary.; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALTIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, N. W. Ryerson Niagara Falls; Secretary, T. S. Young, Canadian Electrical News, Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewit, General Manager Consumers' Gas Company, Toronto; J. Keillor, Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President, J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary. H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, D. McDonald, Manager, Montreal Street Railway; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto, President G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, Killaly Gamble, 703 Temple Building, Toronto.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, J. E. Ganier, No. 5. Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, F. S. Baker, F.R.I.B.A., Toronto, Ont.; Hon. Secretary, Alcide Chausse, No. 5. Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman; Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, J. P. McRae; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Wm Pierce, Calgary; Secretary-Treasurer, John T. Hall, Brandon, Man.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, 115 Phœnix Block, Winnipeg, Man. Second Monday, except June, July and August, at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc.
Printed forms for the purpose will be furnished upon application.

PLANS AND SPECIFICATIONS ON FILE.

The following Plans (P.) and Specifications (S.) are on file for reference only unless otherwise noted at the office of The Canadian Engineer, 62 Church Street, Toronto:—

Bids close		Noted in issue of
5-10	One diesel oil engine, Vernon, B.C. ....(S.)	4-25
5-15	Reinforced arch bridge, Guelph, Ont...(P. & S.)	5-2
5-29	—Water works, sewerage and electric light systems, Melfort, Sask. ....(P. & S.)	5-2

(Melfort plans and specifications are also on file at The Canadian Engineer Offices, 820 Union Bank Building, Winnipeg, and B33, Board of Trade Building, Montreal).

TENDERS PENDING.

In Addition to Those in this Issue.

Further information may be had from the issues of The Canadian Engineer referred to.

TENDERS.

Aylmer, Ont.—Tenders for the several trades in connection with the erection of a Carnegie Free Library at Aylmer, will be received up to May 15th, 1912. Plans, etc., at the office of the architect, W. A. Mahoney, Telephone Building, Guelph, or at the Molsons Bank, Aylmer. D. N. McGregor, Secretary, Aylmer Library Board.

Edmonds, B.C.—Tenders for the construction of a concrete covered reservoir on the Royal Oak Road, in D. L. 158, will be received up to Monday, May 20th, 1912, at the office of W. Griffiths, Comptroller, Edmonds. Particulars may be obtained at the office of the engineers, Cleveland & Cameron, 506 Winch Bldg., Vancouver.

Lunenburg, N.S.—Tenders will be received by Geo. H. Love, Town Clerk, Lunenburg, up to June 1st, 1912, for the construction of a system of sewerage for the town, in accordance with the terms of a report, plans, and specifications furnished to the town by Snow & Barbour, Civil Engineers, and now on file at the Town Office.

Minnedosa, Man.—Tenders for the construction of the spillway, intake, penstocks and power-house foundations of the Minnedosa Power Company, will be received up to May 10th, 1912, at the office of H. F. Maulson, Secretary of the Minnedosa Power Company, Minnedosa, Man. Plans and specifications may be seen at the office of W. Sanford Evans & Company, Grain Exchange Building, Winnipeg, and at the office of F. G. Taylor, barrister, Portage la Prairie, and at the offices of the company at Minnedosa.

Montreal, Que.—Tenders will be received up to noon of Monday, May 20th, 1912, for the demolition of old buildings and the erection of the Montreal City Hall Annex, in Gosford, Champ de Mars and St. Louis Streets. Plans, etc., may be seen at the office of Messrs. Marchand & Haskell, architects, No. 164 St. James St., city. L. N. Senecal, secretary, Board of Commissioners' Office, City Hall, Montreal.

Moose Jaw, Sask.—Tenders will be received until May 15th, for all the works required and necessary in connection with the erection and completion of a brick and stone church building for St. Andrew's congregation at Moose Jaw, Sask. Plans, etc., at the office of T. J. McCammon, Secretary Board of Managers, 57 River Street West, Moose Jaw, or to J. H. G. Russell, architect, Winnipeg.

Ottawa, Ont.—The Department of Public Works will receive tenders up to 4 p.m., on Thursday, May 23, 1912, for the construction of a wharf at Upper Maugerville, Sunbury County, N.B. Plans and specifications with J. K. Scammell, Esq., District Engineer, St. John, N.B.; the Postmaster at Upper Maugerville, Sunbury County, N.B.; and the Department of Public Works, Ottawa.

Ottawa, Ont.—Tenders will be received until May 13th, 1912, for dredging required at Maquapit Lake, N.B. Full particulars at the office of R. C. Desrochers, Secretary, Department of Public Works, Ottawa.

Ottawa, Ont.—Tenders for the construction of a breakwater at Trout Cove, Digby County, N.S., will be received by the Secretary, Department of Public Works, Ottawa, until May 23rd, 1912. Plans, specifications, etc., can be seen at

Barrett Specification Roofs

A CONCRETE CITY

Covered with Barrett Specification Roofs

IN the illustration below the Turner Construction Company, of New York, has brought together in a scale drawing an accurate representation of most of the important modern concrete buildings which they have erected during the past nine years, at an approximate cost of $12,000,000.

It is an imposing display of best types of modern construction—"*a concrete city*" indeed—scientifically designed for maximum service at minimum cost and minimum maintenance.

In the use of concrete, the designers of these buildings planned for economy—the real economy that results from adequate strength and no repairs.

Barrett Specification Roofs are a *real economy*, and it is significant that 95 per cent. of the entire roof area is covered with this type of roofing. The figures are as follows:

Barrett Specification type of Roofs	1,490,523 sq. feet
Plastic Roofings	14,714 sq. feet
Slate Roofings	21,640 sq. feet
Tile Roofings	5,619 sq. feet
Ready Roofings	38,381 sq. feet
Copper Roofings	6,355 sq. feet
All other kinds	7,448 sq. feet

It is important to remember that while all these buildings were constructed by the Turner Construction Company, the specifications were drawn by a large number of architects and engineers. That the great majority of these specified a Barrett Specification type of roof, emphasizes the fact that whenever this roof is practicable the best modern engineering practice will have no other kind.

These roofs were selected for one reason only, namely, that they would give *better* service at *lower cost*, than any other roof covering.

Barrett Specification Roofs require no painting or similar attention—in other words, there are no maintenance costs. They will last upwards of 20 years without any care.

That the above statement is conservative may be realized from the fact that roofs of this type have lasted, without attention, for thirty-five years, and are still in serviceable condition.

The superior economy of Barrett Specification Roofs justifies their adoption not only on big first-class concrete buildings, but on every flat roofed building from a tenement to a skyscraper—from a small mill to a modern manufacturing plant costing millions—but be sure it's a real Barrett Specification Roof—and the only way to be sure is to incorporate The Barrett Specification in full in your plans.

Copy of The Barrett Specification with diagrams free on request. Address our nearest office.

The Paterson Manufacturing Co., Limited

Montreal Toronto Winnipeg Vancouver St. John, N.B. Halifax, N.S.

this department and at the offices of C. E. W. Dodwell, Esq., District Engineer, Halifax, N.S.; E. T. P. Shewen, Esq., District Engineer, St. John, N.B.; and on application to the Postmasters at Yarmouth, N.S., and at Centreville, (Trout Cove), N.S.

Ottawa, Ont.—The time for receiving tenders for widening the Lower Entrance Channel-way, Sault Ste. Marie Canal, advertised to be in on Friday, May 10th, 1912, is extended to 16 o'clock on Monday, May 20th. L. K. Jones, Secretary, Department of Railways and Canals, Ottawa.

Ottawa, Ont.—Tenders will be received by P. E. Ryan, secretary, the Commissioners of the Transcontinental Railway, Ottawa, up to noon of May 31st, 1912, for 200-ton mechanical coaling plants with sand houses and track approaches; also, 1,000-ton coaling station with the inclined trestle approach. Plans and specifications may be seen at the office of Mr. W. J. Press, Mechanical Engineer, Ottawa. (See advt. in Canadian Engineer).

Ottawa, Ont.—Tenders will be received up to noon of May 31st, 1912, for the erection of station and other buildings required along the line of the Transcontinental Railway. Plans and specifications may be seen at the office of Mr. Gordon Grant, Chief Engineer, Ottawa. (See advt. in Canadian Engineer).

Ottawa, Ont.—R. C. Desrochers, Secretary, Department of Public Works, Ottawa, will receive tenders until May 13th, 1912, for dredging required at the following places in the Province of Ontario,—Goderich, Napanee, Picton, Telegraph and Nigger Islands. (See advt. in Canadian Engineer).

Ottawa, Ont.—Tenders will be received at the Department of Public Works, Ottawa, until Wednesday, May 15th, 1912, for the hull repairs and renewals on the C.G.S. "Tyrian." Specifications, etc., may be obtained at the office of the Department, and at the office of C. E. W. Dodwell, Esq., District Engineer, Halifax, N.S.

Ottawa, Ont.—Separate sealed tenders will be received at the office of L. K. Jones, Secretary, Department of Railways and Canals, until May 16th, 1912, for the construction (1) of a brick and stone passenger station at Chatham, N.B., and (2) of a standard (wooden) passenger station and dwelling at Nelson, N.B. Plans, etc., at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa; at the office of the Chief Engineers of the Intercolonial Railway, Moncton, N.B., and also at the station master's offices at Chatham and Nelson for the respective buildings at those places.

Ottawa, Ont.—The Department of Public Works, Ottawa, will receive tenders until Monday, May 20th, 1912, for dredging required at Sault Ste. Marie, Ont. Specifications, etc., at the office of the Department of Public Works.

Province of Saskatchewan.—Tenders for the erection of the following bridges in this province will be called for in a few days from the offices of the Board of Highway Commissioners:—

North-west of Asquith, over Eagle Creek, span 100 feet.
South of Estevan, over Souris River, span 100 ft.
East of Davidson, over Arm River, span 100 ft.
West of Battleford, over Battle River, span 250 feet.
North of Melfort, over Melfort Creek, span 60 ft.
South of Maple Creek, over Maple Creek, span 60 ft.
South of Drinkwater, over Moose Jaw Creek, span 150 ft.
North of Veregin, over Assiniboine River, span 125 ft.
West of Gorlitz, over Whitesand River, span 80 ft.
West of Lumsden, over Wascana Creek, span 80 ft.
West of Sturgis, over Assiniboine River, span 80 ft.
South of Webb, over Swift Current Creek, span 120 ft.

Sault Ste. Marie, Ont.—Tenders for supplying and laying about 21,000 lineal feet of tile sewer pipe with appurtenances, will be received until May 27th, 1912. C. J. Pim, City Clerk; W. W. Van Every, City Engineer. (See advt. in Canadian Engineer).

Sault Ste. Marie, Ont.—Tenders will be received until May 27th, 1912, for the construction of about 169,000 square feet of cement concrete sidewalks and about 21,000 lineal feet of concrete curbing. C. J. Pim, City Clerk; W. W. Van Every, City Engineer. (See advt. in Canadian Engineer).

Toronto, Ont.—Tenders will be received up to noon of May 17th, 1912, for sewer work on Walpole St., McKinley St., Tyrrell St., Davenport Rd., and Oxford St., plans and specifications of which may be seen at City Engineer's office, City Hall. Mayor Geary, Chairman, Board of Control, Toronto.

Toronto, Ont.—Tenders will be received at the office of Frank Barber, Civil Engineer, 57 Adelaide St. E., Toronto, at which place plans and specifications may be seen, for the construction of concrete abutments for a steel bridge 40 ft. clear span, and also for a reinforced concrete truss bridge, 60 ft. clear span and abutments. (See advt. in Canadian Engineer).

Vancouver, B.C.—Tenders for the grading and bridging of the first 10 miles of the Comox extension of the E. & N. Railway, from McBride Junction to Courtenay, will be received, addressed to H. J. Cambie, Chief Engineer, Vancouver, up to May 15th, 1912. Plans, etc., can be seen at the office of R. A. Bainbridge, Divisional Engineer of the E. & N. Railway, Store Street, Victoria. R. Marpole, Vice-President.

Vancouver, B.C.—Tenders will be received up to noon of May 31st, 1912, for the grading, bridging, etc., of the following sections of the Howe Sound & Northern Railway: (a) From end of present constructed line to mile 12.0. (b) From mile 12 to mile 24.1. (c) Branch from mile 2.3 of main line along east branch of Squamish River, 2.7 miles. Plans and specifications may be seen at the office of the Engineers, Messrs. Cleveland & Cameron, 506 Winch Building, Vancouver. Howe Sound & Northern Railway Company, 506 Carter-Cotton Building, Vancouver.

Victoria, B.C.—Tenders for the erection and completion of a four-room school building to be erected on the corner of Cecilia Road and Oliver Avenue, will be received at the office of the Board of School Trustees on or before Wednesday, May 15th, 1912. Drawings, and specifications may be seen at the office of C. Elwood Watkins, architect, Victoria.

Winnipeg, Man.—Tenders will be received by the Chairman, Board of Control, up to noon, May 16th, 1912, for the whole or any portion of the work of repairing the Salter Street overhead bridge. Specifications, etc., at the office of the City Engineer, 233 James Avenue. M. Peterson, secretary, Board of Control Office, Winnipeg.

Winnipeg, Man.—Tenders will be received addressed to H. N. Ruttan, Consulting Engineer, Fort Garry Court, Winnipeg, until May 15th, 1912, for the construction of four miles of pipe sewer in Tuxedo Park, Municipality of Assiniboia.

N. H. Ruttan will also receive tenders until May 15th, 1912. for: 1,400 feet eight-inch, 3,600 ft. nine-inch, and 14,000 ft. of twelve-inch sewer pipe for Tuxedo Park Sewer System. Specifications may be seen at the Consulting Engineer's office.

CONTRACTS AWARDED.

Berlin, Ont.—The municipal councillors have accepted the tender of Messrs. Escher Wyss and Company, for the supply of two turbine pumps with a capacity of 500,000 gallons per day. The Canadian Westinghouse Company will supply the 75 horse-power induction motors for the operation of the above.

Calgary, Alta.—Harold Harvie, Calgary representative of the Canadian Mineral Rubber Company, received word from H. Rowstron, manager of the company, that they have just been awarded a contract for 100,000 yards of asphaltic concrete by the city of Vancouver.

Edmonton, Alta.—Messrs. W. Manders & Co., of Winnipeg, have been awarded the contract for 4½ miles of paving, 20 ft. wide, to cost $160,000.

Grandview, Ont.—Messrs. Schultz Bros., of Brantford, Ont., have secured the contract for the erection of a schoolhouse at Grandview, to cost $33,900.

Hamilton, Ont.—The city council have awarded the following contracts:—That of J. W. Danforth and Company, of Buffalo, for laying the waterworks conduit from the beach pump house to the filtering basins, and the laying of the intake pipe in the lake, for the bulk sum of $61,500. That of Drummond, McCall Company, for one 36-inch gate valve, $500, and four 30-inch at $290 each, for the beach pump house. The Canadian Foundry Company two valves, $725. The Darling Pump Manufacturing Company, two valves, $347. The Coffin Valve Company, for four swing valves, $950.50.

Hamilton, Ont.—Contract has been awarded to the Canada Wire & Iron Goods Co., 182 King William Street, Hamilton for heavy screens for the reformatory at Guelph, Ontario.

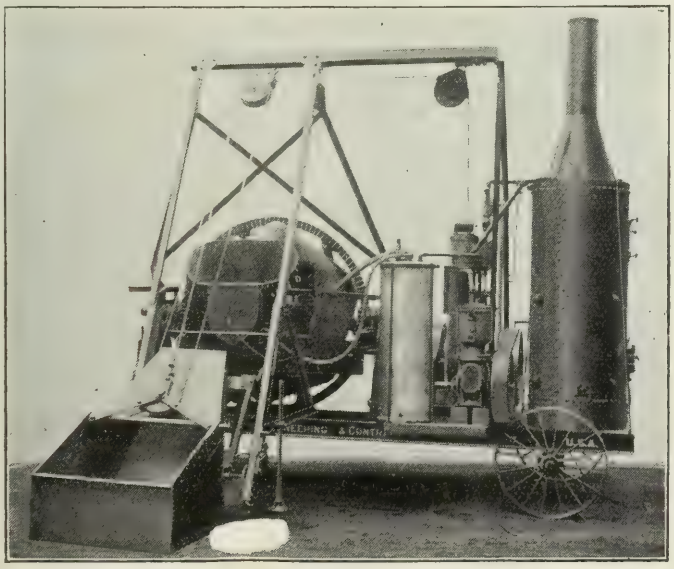
An Austin Improved Cube Mixer



The cube principle of mixing produces the most perfect concrete that can be mixed.

mixes by means of the shape of the drum, which is such as repeatedly to fold the batch as a unit right and left and forward on itself, and squeeze it as a unit into different shapes. **The cube principle is unit incorporation and contact under pressure.** A mixer with inside disintegrators mixes by means of shelves or paddles, which repeatedly break up and toss about the batch in small portions. **The inside disintegrator principle is piecemeal, separation and readjustment.** A study of the two principles of action shows why the cube mixer remains after thirty years the leading concrete mixer on the market.

The Austin Heating Attachment added to the Improved Cube Mixer is a Two-in-One Proposition which means plant economy. It does not interfere in the slightest degree with the Cube Principle of Mixing. It simply makes hot the materials being mixed. No more men are needed than for ordinary concrete mixing. There is no shifting of dampers, no feeding of the fire, no extra manipulation whatever to reduce the speed and mixing accuracy of the machine.

Send for "Special Circular No. 11" describing Cube Mixers with Heating Attachment.

MUNICIPAL ENGINEERING & CONTRACTING CO.

Main Office—Railway Exchange, Chicago, Ill. New York Office:—30 Church St.

CANADIAN EQUIPMENT & SUPPLY CO. Calgary and Vancouver—Agents for Western Canada.

LECKY & COLLIS, Napanee, Ontario, Agents for Eastern Canada.

(AGENTS WANTED IN OPEN TERRITORY.)

High River, Alta.—Contracts for the different branches of the work and the furnishing of materials for the installation of a system of waterworks and sewerage, estimated to cost $125,000, have been awarded as follows:

Contract A—All labor and certain materials necessary for laying water mains and sewers. Tenders: J. A. Broley and Co., Fernie, $27,755.60; Geo. W. Kemper, Minot, N.D., $42,951.25. Awarded to Broley and Co.

Contract C—Furnishing all materials for and erecting steel water tower, capacity 160,000 gallons. Tenders: William Hamilton Co., Peterboro, $8,060; John Inglis Co., Toronto, $8,150; Canadian Fairbanks-Morse Co., $8,436; Canada Foundry Co., $8,990; Chicago Bridge and Iron Works, $8,300. Awarded to John Inglis Co., Toronto.

Contract D—Furnishing cast iron water pipe, 422 tons, and special castings, 10 tons. Tenders: Stewart and Lloyds, Scotland Steel pipe, $17,166; Canada Foundry Co., $19,992.40; Gartshore, Thompson Co. of Hamilton, $20,725.60; Canadian Iron Works, Philadelphia, $25,638.40; Stavely Coal and Iron Co., England, $21,232.26; Canada Iron Corporation, Fort William, $21,006. Awarded to Canada Foundry Co.

Contract E—Furnishing fire hydrants, sprinkling cranes, gate valves and valve boxes. Tenders: Florence Iron Co., $3,706.25; Drummond and McCall, Montreal, $4,552.15; Roe Stevens and Co., $4,228.58; McAvity and Sons, Winnipeg, $3,469.35; Calgary Iron Works, $4,068.55; Canada Foundry Co., $4,384.70; Kerr Engine Co., Walkerville, $4,518.70. Awarded to McAvity and Sons, subject to approval of their style of hydrant by the engineers.

Contract O—All labor necessary for laying main sewer outfall. Tenders: J. A. Broley and Co., $2,940; Geo. W. Kemper, $3,780. Awarded to Broley and Co.

Contract S—Furnishing and delivering sewer pipe connections. Tenders: Red Wing Sewer Pipe Co., glaze tile, $7,092.90; Alberta Sewer Pipe Co., cement pipe, $5,956.50; American Sewer Pipe Co., glazed tile, $6,984.90. Awarded to American Sewer Pipe Co.

Contract W—Furnishing wooden stave pipe, 4,200 feet, and special castings. Tenders: Canadian Pipe Co., Vancouver, $2,309.50; Pacific Coast Pipe Co., Vancouver, $2,187.00. Awarded to Pacific Coast Pipe Co.

Kerrisdale, Point Grey, B.C.—The contract for the laying of sewers to serve the Kerrisdale and Magee districts in connection with the general sewerage scheme has been awarded to George H. Webster, and is estimated to cost in the neighborhood of $153,000. The outfall is down the Kaye Road into the Fraser River.

Penticton, B.C.—Messrs. G. A. Carlson and Company, railway contractors of Spokane, Wash., have secured the contract for 35 miles of road on the Kettle Valley line west of Penticton. Their contract will begin above Trout Creek and run to Osprey Lake, half-way to Princeton.

St. Catharines, Ont.—The Lincoln Construction Company have been awarded the contract for the laying of a duplicate water main under the Welland Canal at a cost of $1,495. The work includes piling and bank protection and according to the wording of the contract must be completed by May 22nd next.

Vancouver, B.C.—Messrs. H. L. Stevens and Company, of this city, have the contract for the erection of the new Molsons Bank of Canada, the building to be of brick and concrete block, 25 by 122 feet. Estimated cost, $80,500.

Victoria, B.C.—The Sydney Brick & Tile Company have secured the contract for the supply of 1,300,000 brick for sewer construction. Their prices were the lowest. Other bidders were Baker Brick & Tile Company, and Victoria Brick & Tile Company, each of which put in tenders of $15 per thousand, and that of Messrs Evans, Coleman & Evans at figures ranging from $14 to $17 per thousand.

Victoria, B.C.—The Seagrave Company, of Brantford, have received the contract calling for the supply of motor apparatus for the Fire Department. This order includes one combination hose and chemical apparatus, one double sixty gallon gas chemical wagon and one chassis for each of the fire engines and city service trucks now at fire headquarters. The total cost for this work is $29,075.

Westmount, Que.—The contracts for sewers on Western Avenue, Mountain Avenue and the Boulevard have been awarded to Messrs. R. G. Smith & Co. Estimated cost, $25,596.

Windsor, Ont.—Waterworks extension: Contractor, Messrs. W. J. Dupuis & Co., Detroit, Mich., and John Inglis and Company, Toronto; cost, $32,400.

Winnipeg, Man.—Preliminary contracts have been let for the construction of the big dry dock and shipbuilding plant at Prince Rupert. Contracts for the building of the piers, landing stage, building platform and launching ways have been given to the British-American Construction Company and representatives of that firm are now at the G.T.P. terminus making arrangements for commencing the work.

RAILWAYS—STEAM AND ELECTRIC.

County of Lanark, Ont.—Messrs. Larkin & Sangster, St. Catharines, are making preparations to begin work on the nine hundred foot tunnel on the new C.P.R. line near Glantay, in this county. The tunnel, which begins beyond Christy Lake, will take a year to construct, gangs working night and day on shifts of ten hours each. The contractors are putting in an air compressor plant that will work ten drills at one time.

Halifax, N.S.—The receipts for the week ending April 30th, 1912, of the Halifax Electric Tramway Company amounted to $5,211.43, an increase of $177.32 over the same period in 1911.

Montreal, P.Q.—Grand Trunk Railway traffic earnings for the period ending April 30th totalled $1,318,817, as compared with $1,125,144 for the last similar period, an increase of $193,673.

Montreal East, P.Q.—The municipality of Montreal East has established a line of autobuses to operate between this municipality and Place d'Armes, in Montreal, a distance of about eight miles. The first machine in operation, which started last week, is of the Berliot type, of twenty-four horsepower, and capable of seating comfortably twenty-eight passengers. The tariff has not been definitely fixed yet, but the rate will probably be ten cents.

Montreal, P.Q.—The new city by-law governing the operation of autobus lines within the city limits has been drafted and will be introduced in council within the next few days. One of the features of the new by-law is that any company operating a motor service must provide a seat for each passenger carried. The capacity of each autobus will be established by officials of the city and this limit must not be exceeded by the company operating the line.

Northern Canada.—A report states that the Government steamer Minto will convey an expedition to the Hudson Bay for the purpose of reporting on the respective merits of Port Nelson and Fort Churchill as the terminus of the Hudson Bay Railway.

Northern Ontario.—A report from Northern Ontario states that twelve miles of the right-of-way of the T. & N. O. Railway has been cleared, and over three hundred men are at work on the construction. Ballasting has commenced on the uncompleted portion of the Porcupine branch, and the depot at Timmins is now being erected. Chairman Englehart is hopeful that work on the new line will be sufficiently advanced to open for traffic by December 1. The outlook for the season's business is bright. A number of settlers are going into the country at points from Liskeard to Cochrane.

Province of British Columbia.—During a sitting of the Dominion Railway Board an edict was issued that provides that all locomotives operating in this province after December, 1914, must consume oil for steam generation. This followed an active movement on the part of the provincial authorities to prevent forest and grass fires during the dry season.

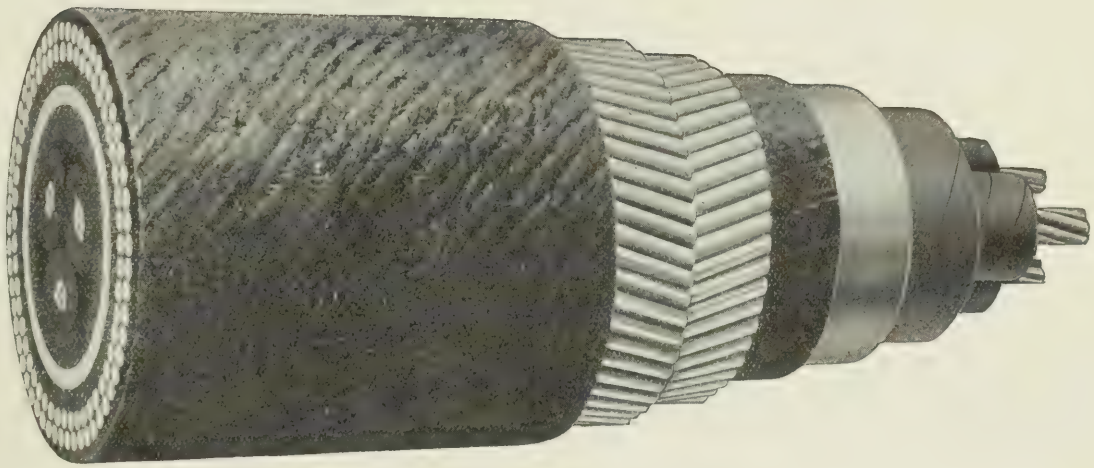
Quebec, P.Q.—It is reported that the Transcontinental Railway, after leaving the Quebec bridge, will descend by the river side for some distance, and will then enter the height of land somewhere about Wolfe's Cove. The location of the exit is not yet settled apparently, but the indications are that it will come out of the hill on a curve about half a mile outside of the city. The estimated cost of the tunnel is from $800,000 to $1,000,000, but if, as is expected, the excavation is seamy and it is necessary to line the tunnel, it may be much more.

St. Thomas, Ont.—Representatives of St. Thomas, Aylmer, Yarmouth and Malahide have practically agreed to guarantee the bonds of the London & Lake Erie Railroad for an extension of the line from St. Thomas to Aylmer.

The Cable across the St. Lawrence River

FROM

Pt. Aux Tremble to King Edward Park.



The longest paper insulated Sub-marine Power Cable on the Continent (supplied and installed by The Canadian British Insulated Co., Ltd., for the King Edward Park Company,) No. 6 B. & S. Gauge, 3 conductor, paper insulated, lead covered double wire armoured and juted.

1½ miles long—13,200 volts

We are prepared to undertake contracts for the Supply and Installation complete of Power Cables under a Five Year guarantee.

WE WANT YOUR ENQUIRIES

Canadian British Insulated Co., Limited

HEAD OFFICE - MONTREAL

Toronto, Ont.—The municipal engineer has recommended that the Board of Control purchase three busses for use between Rosedale and the business centre. The cost of these would be $10,000 each.

Western Canada.—A report that has enjoyed extensive circulation in the West states that large interests are engaged in the matter of electric railway amalgamation and that should the plans mature the principal cities in the Canadian Prairie West will be linked together by electric lines operating under hydro-electric power. It is reported that the management of the Alberta Interurban Railway and the Manitoba Rural Railways Companies are interested in the matter.

LIGHT, HEAT AND POWER.

Hazelton, B.C.—The municipal council are giving serious attention to the latent powers of the falls on the Skena River near this town. It is claimed that 25,000 horse-power could be generated without any serious engineering work being involved, and that should this be accomplished, a large manufacturing district would spring up in the vicinity of this municipality.

Montreal, P.Q.—A report prepared for the municipal Board of Control shows that the cost of civic lighting will cost about $250,000. The estimate is made up as follows: Street lighting, $217,345; special lighting, $1,752; lighting parks and squares in summer, $2,178; lighting municipal buildings, $17,130; relocating lamps, $2,000; salaries of staff, $7,000. Realizing how large the sum is the controllers have studied the subject of municipal electric power. In another year's time the corporation will have completed the enlargement of the aqueduct. As this waterway is to be about three times its present width and nearly three times its present depth the result is that the water supply of the city will be much more than necessary for many years to come. Knowing this the chief engineer has prepared statements showing that it will be possible, with this extra supply of water, to develop power to do most of the street lighting. Not only is it the intention of the city to practically take care of all its street lighting, but the public buildings owned by the corporation will be cared for as well.

Saskatoon, Sask.—The municipal electrical department has shown a surplus despite the fact that reductions of 25 per cent. in power rates and 22 per cent. in lighting rate were introduced in the method of current sales. After allowing for the interest on debentures to the extent of almost $6,000, a depreciation of over $3,000 and a sinking fund of $2,328, a net profit of $2,451 is shown in a statement for the first quarter of the year which has just been made public. Saskatoon is the only city in Western Canada where electrical meters are free to the consumer.

Victoria, B.C.—The municipal council are making arrangements for the installation of a large electric sign to carry the words "Welcome to Victoria, the Gateway of the Pacific." It is to be placed on an eminence and is to be of such size that it will be visable for many miles at sea; thus serving the double purpose of a beacon light and a municipal advertisement.

GARBAGE, SEWAGE AND WATER.

Brandon, Man.—The ratepayers recently voted in favor of authorizing the issue of debentures amounting to $100,000 to be used for waterworks improvement. R. E. Speakman, City Engineer.

District of Muskoka, Ont.—With a view of preventing the pollution of lakes and streams the Provincial Board of Health is issuing dodgers warning the residents of that district against putting any garbage, animal or vegetable matter in the lakes and streams. A fine of $100 is imposed for a violation of this law.

Moose Jaw, Sask.—The ratepayers voted in favor of spending the sum of $60,000 on a new high pressure system in connection with the municipal water works system.

Port Arthur and Fort William, Ont.—The municipal council are having the waterworks system inspected by Mr. T. Aird Murray, of Toronto. It is probable that extensive changes will be made in the near future in this branch of the civic administration.

Sarnia, Ont.—Recent experiments conducted by City Engineer McLean to obtain information regarding the quality of water resulting from soakage through 30 feet of sand into test wells, resulted favorably. He plans to install a turbo-generator of 500-k.w., at the present water works, and from this operate pumps attached to about twenty additional wells.

BUILDINGS AND INDUSTRIAL WORKS.

Brandon, Man.—The ratepayers recently voted in favor of spending the sum of $33,000 to erect a new fire hall. R. E. Speakman, City Engineer.

Calgary, Alta.—Plans for the expenditure of $975,000 on new schools and school sites, $800,000 of it for the erection of schools, and $175,000 for the purchase of new sites to be held for future contingencies, were drawn up at a special meeting of the Calgary school board recently. Subject to the approval of the ratepayers, debentures are to be issued for $75,000 for 40 years at 4½ per cent.

Calgary, Alta.—Mr. G. D. Venine is preparing to erect an office and store building of brick and fireproof materials to cost $20,000.

Edmonton, Alta.—Plans have been prepared for the erection of a new Anglican Church to cost about $100,000. The new building, as planned, will be 150 feet long by 75 feet wide. The ground floor, raised five feet above grade and approached by three flights of steps from a wide vestibule will comprise the nave and side aisles, seating about 900, chancel with choir accommodation of 65, two transepts and large sanctuary and sacristy. Messrs. Barnes and Gibbs are the designers.

Fredericton, N.B.—The University Senate have announced their intention of erecting a substantial new grand stand at the atheletic grounds. It is to be constructed as soon as possible.

Hamilton, Ont.—Mr. H. H. New is preparing plans for the erection of a new children's hospital to cost $32,000.

Lethbridge, Alta.—The Free Masons of this city have made arrangements for the erection of a new hall to cost about $40,000.

Montreal, P.Q.—Plans have been prepared for a city hall annex and have been approved by the municipal council. The new structure will have a fine appearance and will do away with much congestion at the City Hall. In it will be situated the Recorder's Court, police headquarters, and health department. The annex will be four stories in height with granite foundations and a superstructure of sandstone. Tenders will be called at once for the erection of the building.

Moose Jaw, Sask.—The Saskatchewan Bridge and Iron Company have awarded the contract for the erection of their new machine shed on Fairford Street west to the Western Building Company. The new shed will be of iron-clad and steel construction 50 by 150 feet. The cost will be about $125,000.

Montreal, P.Q.—Mr. J. W. Birchenough will erect a $60,000 building on the corner of Bleury Street and Alexander Street.

Nelson, B.C.—Mr. E. Ross Mackenzie is interested in a project to erect a new opera house of brick, four stories in height to cost about $65,000. There will be seating capacity for about 900 persons.

Ottawa, Ont.—The Federal Government are considering the erection of dry-docks at the following points in Canada: St. John, N.B.; Quebec, P.Q.; Montreal, P.Q.; Toronto, Ont.; Sydney, N.S., and Prince Rupert, B.C. The docks at Collingwood, Ont., and Halifax, N.S., are to be extended.

Pincher Creek, Alta.—Plans that have been prepared for the erection of a new town hall for this municipality show a handsome building of brick, two storeys in height, with a large central tower above the main doorway.

Princeton, B.C.—Mr. Peter Swanson is having plans prepared for a hotel to cost $50,000.

Quebec, P.Q.—A report states that the Federal Government are considering the matter of reconstructing a portion of the breakwater at this point. This work will cost, according to the estimate, about $500,000.

Regina, Sask.—Plans have been prepared by Mr. F. N. Darrach for a new church building to be erected for the congregation of Westminster Presbyterian Church. They show a building with an arch at the entrance which will be support-

THE TRIPLEX BLOCK

A Triplex Block hung from a temporary rigging and used for laying pipe.

What is the Life of a Triplex Block?

WE don't know. Triplex Blocks built by the Yale and Towne Co. at the very beginning—twenty-five years ago—are still in actual use. The Triplex Block of to-day possesses greater lasting powers. With its steel parts—its chain superior to any other—its non-wearing gear movement—and the guarantee of a rigorous test before shipment under a fifty per cent. overload. It will outlast the man who buys it, no matter how young he may be.

ed by four pillars set about halfway up the flight of steps, the doors being set well in from the pillars. The gable over the arch is high, and has a large window. The Sunday school adjoins the church. The cost of the work will be about $70,000.

Saskatoon, Sask.—A new company taking the name of the Concrete and Supply Company, has been formed with Mr. C. D. Fisher as president. The new company will manufacture cement, brick, Roman stone, and other ornamental stone. The plant is to be erected on the corner of Avenue L and 17th Street.

Saskatoon, Sask.—A report states that a Winnipeg firm contemplates erecting a seven-story building to be used for apartments and stores.

Saskatoon, Sask.—Dr. J. H. C. Willoughby and Mr. A. J. E. Sumner are preparing to erect a four story departmental store which is to be occupied upon completion by F R. McMillan & Co.

Sydney, C.B., N.S.—The firm of Mackay and Maxwell are having plans prepared for the erection of a new automobile garage to cost about $10,000. A recharging tank with appliances for recharging the new prestolight and searchlight tanks will be installed. An air pump attachment for tire pumping will be introduced also.

St. John, N.B.—Negotiations are under way for the transfer of limestone properties and the erection of a cement plant. The municipal council have agreed to sell the property for $26,200, on condition that the purchasers erect the plant and a report states that the deal only awaits ratification by the council.

St. Catharines, Ont.—A report states that the management of the Warren Axe and Tool Company, of Warren, Pa., U.S.A., propose the erection of a plant in this city. The ratepayers will vote on the question of the usual subsidy on May 9th.

St. Catharines, Ont.—A report from this city states that the management of the Reo Motor Car Company are contemplating the erection of a new factory in the vicinity of Berryman Avenue. About 80,000 additional square feet of floor space are required by the company as soon as possible.

Toronto, Ont.—The Toronto and Niagara Power Company intend to build a structural steel plant at the northeast corner of Shaw and Dupont Streets. The plant will cost $40,000.

Toronto, Ont.—The National Iron Works will commence work on an addition to their concrete dock.

Vancouver, B.C.—A report states that the management of the Canadian Home Investment Company have recently purchased a site in this city and contemplate the erection of a ten-story building to cost $1,000,000.

Vancouver, B.C.—The Northwest Commercial Travellers' Association have made preliminary arrangements for the erection of an office building in this city. The cost is estimated at $160,000.

Victoria, B.C.—Plans are being prepared by Thomas Hooper, Royal Bank Building, for a Women's Home to cost $19,000.

Windsor, Ont.—The National Auto Body Company, has been organized with a capital of $150,000. The company will manufacture auto bodies of wood, steel and aluminum, and will also build, trim and paint both open and closed bodies. A site covering three acres has already been purchased in the factory district and tenders calling for the construction of a number one plant have been advertised.

BRIDGES, ROADS AND PAVEMENTS.

County of Haltan, Ont.—The members of the county council are about to spend the sum of $[illegible]00,000 on road improvements covering over one hundred miles.

North Vancouver, B.C.—The estimated cost of constructing a bridge across the Second Narrows has been increased from $120,000 to $150,000.

Township of Morris, Ont.—The councillors of this township have found it necessary to issue debentures for the sum of $23,000, in order to replace the bridges which were swept away by the recent flood.

South Porcupine, Ont.—A large trestle bridge (200 foot) was destroyed by fire recently. It was on the line of the T & N.O. Railway seven miles south of Dane.

Toronto, Ont.—The civic engineering department has recommended the construction of an asphalt pavement on Bloor Street to cost $51,813. This will be from Bathurst St. to Dufferin St. The Works Committee are considering the question of widening the pavement on Spadina Avenue from 52 feet to 91 feet, at a cost of $35,231. This is from Queen St. to Baldwin.

FIRES.

Stratford, Ont.—The factory of Messrs. Totton Co.'s Willow Cheese manufacturers, was damaged by fire.

Treherne, Man.—Damage to the extent of $70,000 was caused by fire to the business section of this town. Among the damaged buildings the name of J. Adair & Son's implement warehouse appears.

Victoria, B.C.—The plant of the Canadian Puget Sound Lumber Mills was recently badly damaged by fire. This plant is at Rock Bay on Victoria Harbor.

CURRENT NEWS.

Brantford, Ont.—The ratepayers will vote on a by-law calling for the expenditure of $13,000 for improvements to the dyke system.

Collingwood, Ont.—The Collingwood Shipbuilding Company will construct a large freight ship for the Chicago and St. Lawrence Navigation Company of Toronto. It is to be ready for the opening of navigation in 1913 and will be the largest freighter operating on the lakes having a cargo capacity of 12,0000 tons. The dimensions are: Length over all, 550 feet; width between perpendiculars, 58 feet; moulded depth, 31 feet. The vessel will be built on the arch web system of framing, and will be fitted with side tanks and water bottom for her entire length. There will be 32 hatches with steel telescoping covers. The propelling machinery will be a vertical triple expansion engine, the cylinders being 24 in., 40 in., and 66 in. in diameter, with a 42-inch stroke. The steam will be supplied by three cylindrical boilers, each 13 feet in diameter, with a working pressure of 85 lbs., and they will be fitted with Howden's system of forced draught. The ship and machinery throughout will be built to the highest classification of the Great Lakes register. The vessel will cost complete about $375,000. Mr. W. D. Matthews is the president of the Chicago and St. Lawrence Navigation Company.

Hamilton, Ont.—The municipal council are seriously considering the question of purchasing auto trucks for hauling on civic works. The secretary of the Board of Control has been requested to secure prices and operation costs. Mr. A. F. MacCallum is the city engineer.

Nelson, B.C.—The management of the Nelson Gas & Coke Company have made overtures to the municipal council for the sale of their plant. They ask $75,000 for the business.

Ottawa, Ont.—The Civil Service Commissioners have announced that applications will be received for the position of architectural draughtsman in the chief architect's division, (Initial salary $1,300 per annum), and two draughtsmen in the same department with a salary of $800. Applications must be filed in the office of the Civil Service Commission, not later than the 20th day of May next.

Quebec, P.Q.—The Harbor Board of this municipality have arranged a plan of improvement which will cost about $1,000,000. A car ferry and a large grain elevator are on the list of improvements.

PERSONALS.

Mr. Arthur J. Demster, of Toronto, has been awarded the Science Research Scholarship by the senate of the University of Toronto.

Mr. Richard W. Allen, of the well-known firm of W. H. Allen, Sons & Co., Ltd., Bedford, England, was a visitor to Toronto this week.

Mr. L. K. Jones has been appointed to the position of Assistant Deputy-Minister of the Department of Railways and Canals for the Federal Government.

THE RED RIVER BRIDGE FOR THE NATIONAL TRANSCONTINENTAL RAILWAY

By D. C. TENNANT, B A., Sc *

PART 2.

The Strauss Bascule span of the National Transcontinental Bridge over the Red River is of the so-called Heel Trunnion type, the Main Trunnion being placed at the heel of the moving leaf. Plate No. 3 shows an elevation of the whole span and Plate No. 4 indicates in a general way the stresses and material of the more important parts.

Relative to the D.L. pier reactions in this type of bridge, it should be noted that since the moving leaf is at all times perfectly balanced, there is no D.L. reaction at the front end, and the weight of the entire structure is, therefore, carried by the two tower piers. Disregarding for the sake of simplicity the weight of the counterweight link and the operating strut, the reactions are due to:

1. The weight of the tower.
2. The weight of the moving leaf.
3. The weight of the counterweight including trusses and bracing.

Fig. 6.—General View of Bascule.

(1) The reactions due to the weight of the tower are vertical and constant.

(2 and 3) The moving leaf and the counterweight are supported on the tower as on a carriage; they do not rest directly on the pier, and if the tower is properly designed, it takes care of all the horizontal forces, the horizontal component of the main trunnion reaction neutralizing the horizontal component of the counterweight trunnion reaction through the tower.

It follows that the pier reactions due to the weight of the moving leaf and the counterweight are vertical. Furthermore, they are constant during the opening and closing of the bridge. Owing to the fact that the four pins, main trunnion, counterweight trunnion and first and second link pins are located in the corners of a parrallelogram, the angular movements of the moving leaf and the counterweight are the same, and as the weight of the moving leaf is as much smaller than that of the counterweight as the lever arm of the latter is smaller than that of the former, it follows that the centre of gravity of the system as a whole is not disturbed during the operation of the bridge, and, therefore, the pier reactions cannot vary. This proved, it can be seen that the D.L. reaction on the main trunnion pier (disregarding the reaction due to the weight of the tower) is equal to the weight of the moving leaf and the D.L. reaction on the counterweight trunnion pier equal to the weight of the counterweight. If, namely, the bridge is open to such an angle (about 90 degrees) that the centre of gravity of the moving leaf falls directly over the main trunnion, then at the same time the centre of gravity of the counterweight falls directly below the counterweight trunnion; the trunnion reactions have no horizontal components and it becomes evident that of the two piers the one carires the moving leaf and the other the counterweight.

In considering the reaction on the main trunnion, we note that the moving leaf is subject to three outside forces only, viz.:—

*Chief draughtsman with the Dominion Bridge Company, Montreal. Mr. Tennant is an honor graduate of the Faculty of Applied Science and Engineering University of Toronto.

NOTE.—The first part of this article was published in *The Canadian Engineer* of April 18th.

1. The weight of the moving leaf, which is a vertical force passing through the centre of gravity of the moving leaf.

2. The link stress (link pin reaction) which passes through the second link pin and which coincides in direction with the counterweight link. Since this pin is connected at both ends and would not be in equilibrium under any other condition.

3. The main trunnion reaction.

Since the bridge is balanced this third force must pass through the point of intersection of the two others. When the bridge is closed this point of intersection falls near the centre of the span and somewhat below the bottom chord and the D.L. main trunnion reaction is, therefore a force which passes through the trunnion and is directed towards the point of intersection, while the moving leaf butts against the trunnion in a direction that is inclined slightly upwards and towards the tower. It follows that according to the design the base (or body) of the main trunnion bearing, which is rivetted to the heel of the bascule truss, will always bear against the trunnion, which is keyed to the tower truss, and that the cap on this bearing might, therefore, be omitted if it were not for practical reasons (lubrication, etc.). This also is shown by analyzing the stress in the truss members. The D.L. stresses in the four members intersecting at the hip point (2nd link pin), including the end post, are all tension. Of the two members intersecting at the main trunnion, the D.L. stress in the end post is tension, as stated, while the D.L. stress in the bottom chord member is compression and the resultant of these two forces is a force inclined slightly upward and acting away from the moving leaf against the tower, which again produces a reaction from the tower, as described above.

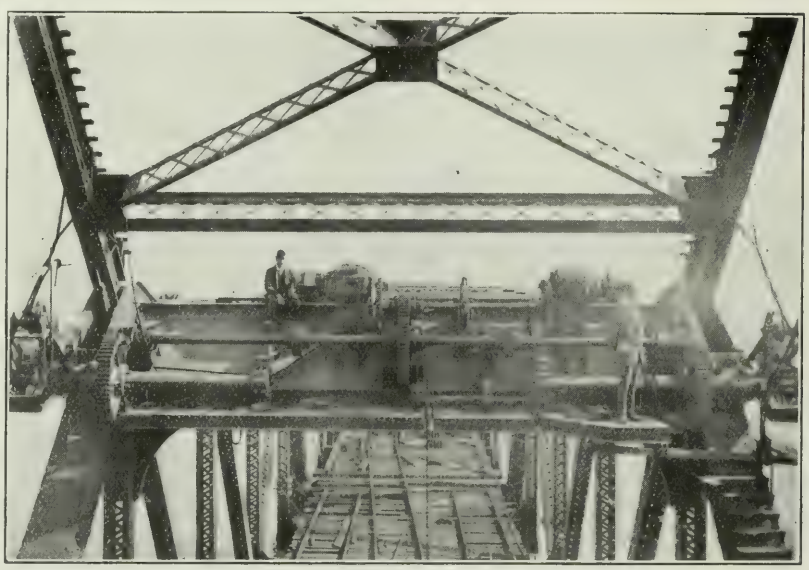

Fig. 2.—Portal and Machinery of Moving Leaf, as Seen from Counterweight Tower.

The L.L. reaction on the trunnions and the L.L. stresses in the truss members are in no way different from those in an ordinary truss. The thrust of a train (breaking load) coming from the trunnion end of the bridge, however, will tend to push the moving leaf away from the trunnion (that is, produce bearing on the cap of the trunnion box and tension in the cap bolts), but in all cases so far investigated, this force has not been sufficient to overcome the D.L. going in the opposite direction, and it could in any event be properly cared for by making the cap sufficiently strong.

In designing the bascule span, the regular Dominion Government stress of 16,000 pounds per square inch for tension was used, but compression stresses were not allowed to exceed 13,000 pounds per square inch, and stresses, either tension or compression with the bridge moving were kept down to 13,000 pounds per square inch.

The moving leaf spans a clear waterway of about 110 feet, and in general outline it resembles the four 150-ft. fixed spans between the east abutment and pier No. 4. The trusses are 32 ft. 8 in. deep centre to centre of chords and are made up of five panels, the one next the main trunnion being 30 ft. 10 in. and the other four 24 ft. 8 in. each, making a length centre to centre of 129 ft. 6 in. The cuts in the floor of the bridge are made at the front end of the bascule and at a point a few feet east of the main trunnion, so that the floor of the moving leaf will in both cases lift from the fixed floor when the bridge is opened. The end floor beam at the trunnion end is set 6 ft. 2 in. east of the trunnion, making a span for the stringers in the end panel of 24 ft. 8 in., or the same as in the other four panels of the moving leaf. The front end of the moving leaf is received when the bridge is closed on two cast steel pedestals securely anchored to pier No. 4. These pedestals have tapered cast steel guides fastened on top of them so that the span descending to its horizontal position is brought into perfect alignment with the rest of the bridge. There is no dead load reaction at this end of the moving leaf so the span is latched to the pedestal to keep it in position. There is a latch on each side attached to the ends of the trusses and operated by an electric motor fastened to the bottom chord. The latches can also be worked by hand.

The moving leaf and the counterweight are supported on a triangular tower spanning between piers No. 5 and No. 6, a distance of 40 feet, which is the horizontal distance between the main trunnion and the counterweight trunnion. The vertical position of the concrete counterweight is governed by the height of 22 ft. 6 in. clear beneath it, necessary for trains when the bridge is closed. The horizontal distance from the counterweight trunnion to the centre of gravity of the counterweight, is governed by the necessity of its swinging clear of the top of the rails when the bridge is open. As the two link pins and the two trunnions form the four corners of a parallelogram the angular motion of the counterweight will be equal to the angular motion of the moving leaf, or 80 deg. 30 min. when the bridge is fully open. The line joining the main trunnion with the centre of gravity of the moving leaf will point slightly upward, therefore the line joining the counterweight trunnion with the centre of gravity of the counterweight must point slightly downward and the weight of the counterweight is greater than that of the moving leaf in proportion as its leverage is less.

As will be seen by referring to Plate No. 3, the trusses of the moving leaf and of the counterweight frame itself are set with their centres 31 ft. 3 in. apart centre to centre transversely. These bear against the main trunnion and counterweight trunnion pins which are at right angles to the centre line of the tracks and span, a distance of 5 ft. 0 in. transversely, their outer ends being supported on the trusses of the main tower, which consequently are spaced 36 ft. 3 in. apart centre to centre. The inner ends of the main trunnions are supported on auxiliary shoes 26 ft. 3 in. apart resting on pier No. 4, and the horizontal component

of the thrust on these shoes is resisted by a girder with horizontal web 9 ft. deep extending from the back of the shoes to the first panel point in the counterweight tower. The inner ends of the counterweight trunnions are supported on auxiliary posts 26 ft. 3 in. centre to centre, carried on a cross truss 7 ft. 9 in. deep centre to centre of chords spanning between the main vertical posts of the counterweight tower. The horizontal component of the thrust on these auxiliary posts is resisted by an inclined truss spanning between the inclined top chords of the tower. The tower is divided into three panels, two of 12 ft. 6 in. and one of 15 ft. 0 in, the long one being next the counterweight trunnion. The vertical distance centre to centre of trunnions and consequently the height of the tower centre to centre is 40 ft. 3½ in. The stringers and floor beams of the floor are similar to those of the moving leaf, but the floor beams are longer owing to the greater width centre to centre of trusses. On account of the great width and short span, together with the presence of the horizontal stiffening girder, no bottom laterals were deemed necessary. The main verticals are stayed against vibration and wind action by a system of wing bracing anchored to the concrete pier 7 ft. 2 in. from the C.L. of the trusses with four 3½-in. anchors running 15 ft. into the masonry. The base of this wing brace rests on a grillage of five 24-in. I's at 100 lbs., 13 ft. long, continuous under the brace and the main post, and this grillage, the anchors for the wing brace and also four 1¾-in. anchors 6 feet long for the main post were set while the masonry was being built, the grillage being embedded in the concrete, flush on top. The main trunnion shoes of the tower trusses and the auxiliary shoes rest on longitudinal shallow girders 15 inches deep, built up of plates and angles with stiffeners, these in turn resting on two grillages, one under each trunnion composed of six 18-in. I's at 65 lbs., 10 feet long, running transversely. Each shoe is anchored with four 1¾-in. bolts running 11 ft. 0 in. into the masonry and the built girders, grillages and anchors were all set in place while the concrete was being built, the tops of the girders being flush with the top of the pier.

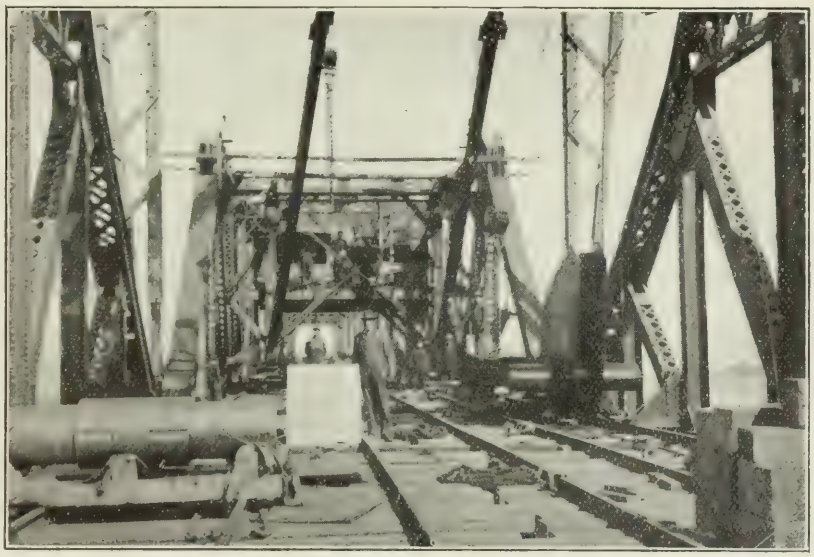

Fig. 3.—Looking from Counterweight Tower Towards Moving Leaf. Showing Erection Traveller About to Raise Counterweight Trunnions to Place.

The counterweight frame is of the dimensions and material noted on Plate No. 4. The joints at the counterweight trunnion and the first link pin were well reinforced with plates to take the bearing of the pins and the main gusset plates were extended beyond the sides of the main members, the outer edges being reinforced by stiffener angles curved to conform to the outline of the plate. (See Plate No. 3.) This was also done on the main trunnion shoes and on the moving leaf at the second link pin. The weight and position of the concrete in the counterweight was finally carefully calculated from the shipping weights of the various members composing the counterweight frame and the moving leaf. The concrete is composed of one part cement, three parts sand, and five parts gravel, and was found by trial to weigh 141 lbs. per cubic foot when dry. Four large pockets were left which, after the concrete was dry, could be either totally or partially filled with concrete adjusting blocks weighing from 350 to 700 pounds each. As finally calculated, the total weight of concrete necessary was 1,756,000 pounds, so the dimensions were arranged to provide for 1,656,000 pounds and the pockets, if filled, would give 200,000 pounds extra. Thus the bridge would balance with the pockets about half full. Tests on the bridge since completion prove the assumptions to have been substantially correct.

The main trunnions are turned pins 16½ inches dia. They are supported on built shoes and are keyed to cast steel collars which are fastened to the shoes with turned bolts. The thrust from the moving leaf is applied through a cast steel box, bolted between the gusset plates of the moving leaf which in turn are stiffened up with radial diaphragms. The steel box has a cap fastened on with six 2¾-in. studs, and is fitted with a phosphor bronze bushing to take the wear. Lubrication takes place through the counterbore of the trunnion, which is connected with the surface of the pin by these canals, and there are no grease cups in the cap.

The counterweight trunnion is a 22-inch turned pin, keyed to the counterweight frame. It is reduced to 18½ inches at the ends where it runs in cast steel boxes resting on the top of the tower. These boxes also have cast steel caps and compression grease cups in the caps.

The stress in the counterweight link will vary from zero when the centres of gravity of the moving leaf and the counterweight are respectively directly above and directly below the trunnions to a maximum when the bridge is closed. The link pins, both first and second, are 8 inches dia. Inside the gusset plates of the trusses the pins are surrounded by cast steel collars 19 inches dia., bolted to the gussets. The link bears on these collars. The ends of the link are fitted with cast steel bearing collars and bronze bushings lubricated from compression grease cups.

The bridge is operated by an operating strut pin connected to the top chord of the tower at one of the intermediate panel points. This strut has bolted to its under side a cast rack which engages a pinion on the moving leaf near the hip joint, the pinion being held in mesh with the rack, by means of a carriage with rollers bearing against the top and bottom flanges of the operating strut. This pinion is driven by means of two 40 h.p. electric motors and a series of gears that are very clearly shown on Photo No. 4. The portal at this end of the moving leaf consists of two girders, one with a vertical web and one with web inclined at the same slope as the post, as shown on Plate 4. From the bottom of these two girders a platform is cantilevered out towards the counterweight tower and the

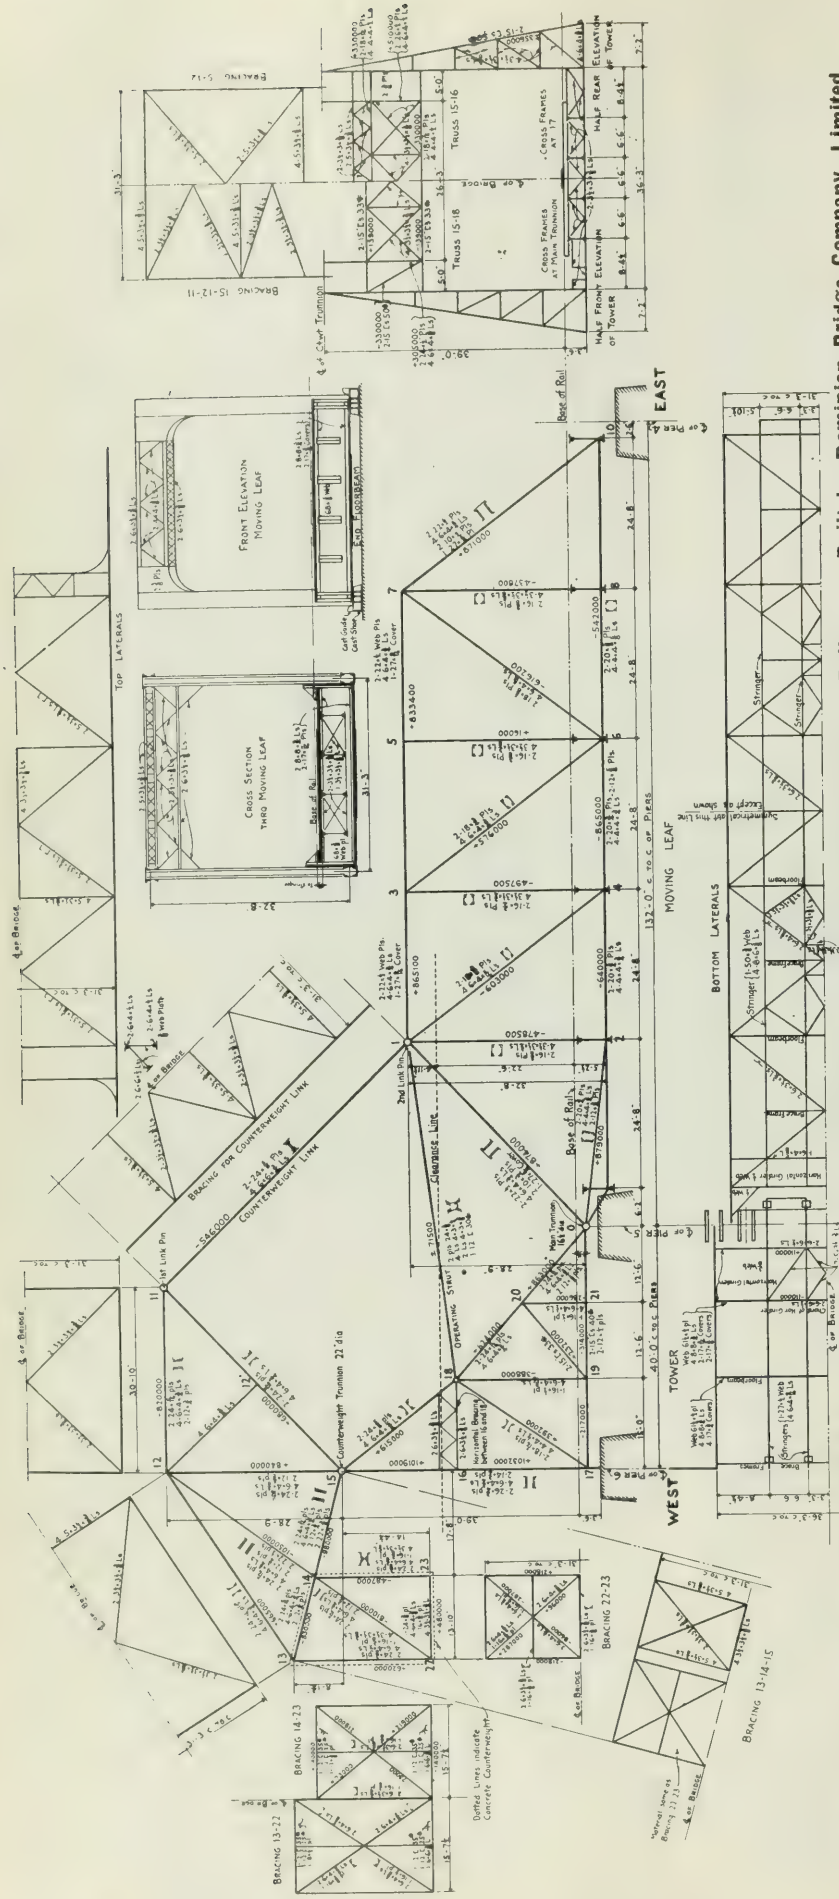

Plate A.—The Strauss Trunnion Bascule Span of the Red River Bridge for the National Transcontinental Railway., Built by Dominion Bridge Company, Limited.

machinery is carried on this platform and the portal. The lubrication of this machinery was arranged so as to be effective at any position of the bridge. The bridge can also be operated by hand from the lower deck by a chain.

The operator's cabin is situated on the south side of the bridge and rests on brackets that cantilever from the outside of the tower truss almost directly over the main trunnion. It is indicated on Plate No. 3, but has two stories instead of only one, as shown on the plate. The upper story was added to accommodate the storage batteries to operate the electric interlocking signals controlling the approaches to the bridge. It contains the switchboards from which are operated the main driving motors of the bridge, the motor for the latches on the toe of the moving leaf, the brakes, etc. An automatic cut out is arranged to prevent the bridge from opening a greater angle than 80 degrees 30 minutes or the fully open position. Automatic signals indicate for the railway and for navigation, when the bridge is open and when shut.

Since the first four heel trunnion bascules were designed, namely, the Red River bridge, the Cape Cod Canal bascule for the New York, New Haven and Hartford Railway, the Illinois River bridge for the Peoria and Pekin Union Railway, and the Ashtabula Harbor bascule for the Lake Shore and Michigan Southern Railway, a change has been made by the Strauss Co. in the design, putting the tower trusses in line with those of the moving leaf and counterweight frame, thus obviating the necessity of long trunnion pins spanning between two shoes and simplifying the details generally. It might be stated here that the Baltimore and Ohio bridge over the Calumet River, which is a 235-foot double track bascule, and the Canadian Pacific bridge over the Sault Ste. Marie Canal, which is a 336-foot single track span, are respectively the longest double track and single track bascules in the world.

Erection was begun from the east end of the four 150-ft. truss spans and continued westward till the bascule, the viaduct, and the spans over Notre Dame Street and Water Street, were completed, the spans at the east over the Canadian Northern and Tachè Avenue being put in last. The erection scheme will be better understood by referring to Plate No. 1 in the issue of *The Canadian Engineer* of April 18. The material was delivered by rail on the Canadian Northern tracks close to the east shore of the Red River. From the cars it was raised to the level of the Transcontinental tracks as required. The fixed truss spans and the bascule were erected on wooden falsework resting on the river bottom. The special erection traveller that was used is shown in Photo No. 5.

It also appears in Photos No. 2 and No. 3 of the issue of April 18. It was desirable to use the same traveller for the truss spans and the viaduct. It therefore had to be made low enough to go under the sway bracing of the truss spans. As the bridge was double track, the traveller was made as wide as the through trusses would permit, and carried a mast and boom on each side capable of being operated independently. Since the viaduct has quite an appreciable curve the wheels of the traveller were specially arranged to take the curve easily. This was accomplished by placing an ordinary car truck of four wheels at each corner of the traveller. The centres of the four trucks formed a base of 27 ft. 6 in. longitudinally by 18 ft. 0 in. transversely, the traveller running on two tracks of standard gauge with a width of 18 ft. 0 in. centre to centre of tracks. The frame of the traveller was made entirely of wood. The two trucks on each side are 27 ft. 6 in. apart, supported longitudinal wooden trusses 6 ft. 0 in. deep. These each had a vertical mast in front 18 ft. 6 in. high of 12 x 12 timber, the top of each mast being stayed to the bottom chord of the wooden truss at a point over the back truck, by two 1⅜-in. square steel tie rods. The booms were of 12 x 12 timber 35 ft. 0 in. long, and were capable of lifting 10 tons each. Across the tops of the wooden trusses were laid 6 x 12 cross ties 19 feet long, and to these was spiked the floor of the traveller. The engines rested on this platform, being placed over the back trucks in an enclosed cabin. Thus, under the centre of the traveller there was a clear head room of about eight feet under the cross ties or the height of the trucks plus the height of the truss. There was also a clear width underneath of about 12 feet between the trucks. In this space a third track of standard gauge was run along the centre of the bridge and on this track the material was brought on hand trucks from the delivery tracks at the east end of the bridge forward to the front side of the traveller within range of the derricks. This traveller erected all the truss spans and approach girders, except the more elevated members of the tower and counterweight which were put up with a gallows frame. The forms for the concrete of the counterweight were supported on heavy woodwork resting on the most easterly girder span of the long viaduct.

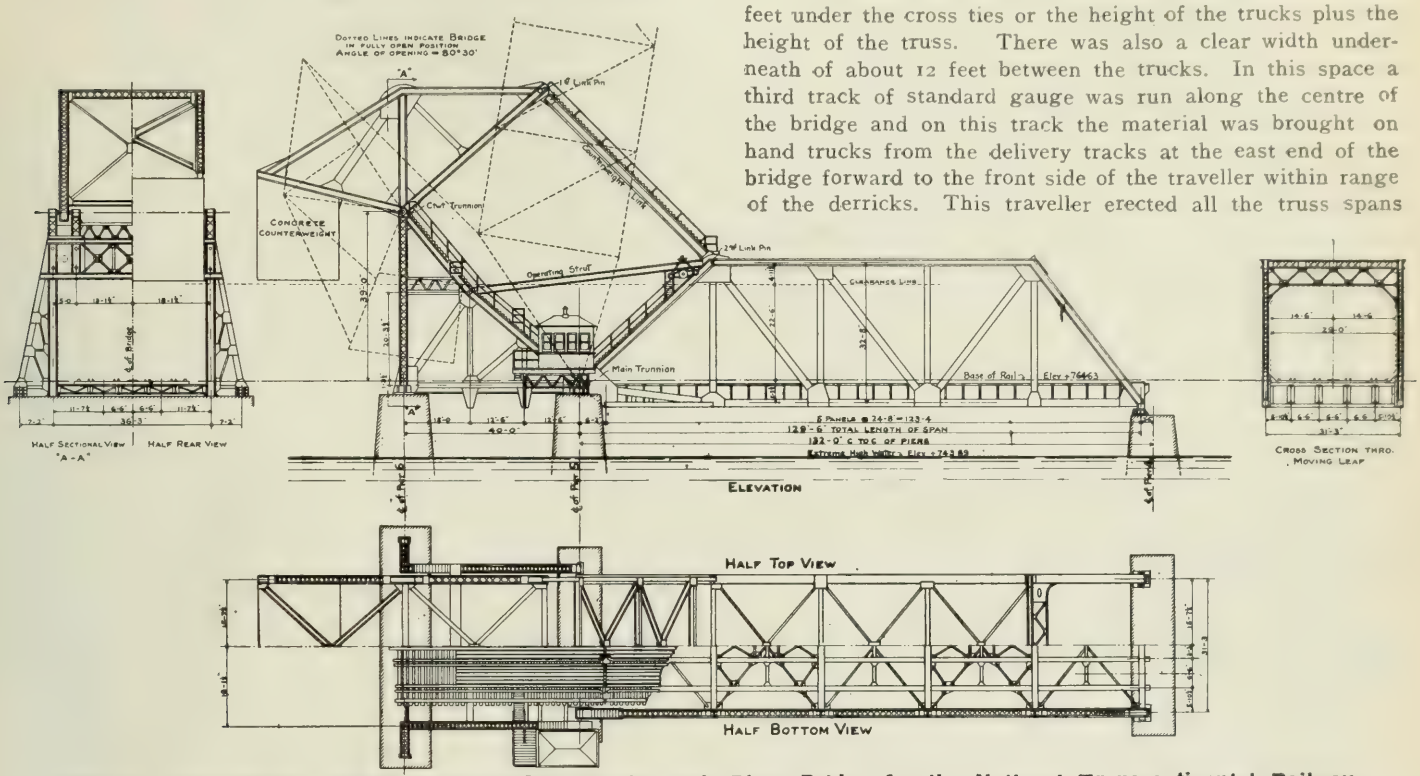

Plate 3.—The Strauss Trunnion Bascule Span of the Red River Bridge for the National Transcontinental Railway. Built by Dominion Bridge Company, Limited.

In conclusion the writer wishes to most heartily thank Mr. Uniacke, the bridge engineer of the Transcontinental Railway, and Mr. Jeppesen, the designing engineer of the Strauss Bascule Bridge Co., for photographs and other information in connection with the bridge; without the co-operation of these gentlemen and also of the Dominion Bridge Co., this paper would not have been possible.

FAREWELL BANQUET IN HONOR OF CITY ENGINEER RUST AT ENGINEERS' CLUB, TORONTO.

Last Friday evening about ninety members of the Engineers' Club of Toronto, representing all phases of the engineering profession, sat down to a complimentary dinner in honor of Mr. C. H. Rust, City Engineer of Toronto, who left this week to assume his new duties as City Engineer of Victoria, B.C.

Mr. Willis Chipman occupied the chair, on the right of whom sat the guest of the evening, Mr. C. H. Rust, and on his left Mayor Geary. Other representatives of the city's life who were present and joined in this testimony to Mr. Rust's worth, character and ability were R. T. Coady, city treasurer; F. S. Spence, vice-chairman of the Harbor Commission; H. L. Drayton, corporation counsel; Alex. C. Lewis, secretary of Toronto Harbor Commission.

Mr. J. G. Sing, resident engineer for Department of Public Works, proposed the toast to the guest of the evening. Mr. Sing referred to the loss not only the engineering profession would suffer by Mr. Rust's removal to the coast, but also the loss to the public life generally. He also spoke of the high character of Mr. Rust's work in Toronto during the past years.

Responding to the toast, Mr. F. S. Spence supplemented Mr. Sing's remarks and paid special tribute to the integrity and uprightness that Mr. Rust had always displayed in his municipal life. Following this Mayor Geary made a few remarks along the same lines to which Mr. Rust responded, and with some feeling referred to the breaking of connections with a city with which he had been so long identified.

At the conclusion of the proceedings Mr. Rust was presented with a bound souvenir menu containing the autographs of all the guests.

SELECTION OF A WATER-WHEEL UNIT.*

By O. B. Coldwell.

(Continued from last week.)

It is interesting to note, from Fig. 7, that where K = 20 with loads varying from 70 to 100 per cent. of full load, the per cent. of full load efficiency varies from 100 to 103 per cent. If therefore, the full load efficiency of this particular runner is 82 per cent., the actual efficiency between 70 per cent. and full load would be somewhere between 82 per cent. and 0.82 × 103 or 84½ per cent.

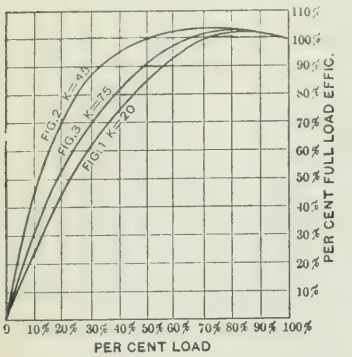

Fig. 7.
Comparative Efficiency Chart.

Let us consider Fig. 8. Here we have plotted the maximum actual efficiency against specific speed. It has been found by experiments which have been made by a number of manufacturing companies

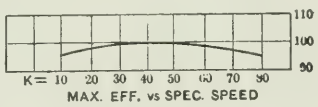

Fig. 8.

from time to time that the specific speed resulting in the highest efficiency is somewhere between K = 40 and K = 50.

A consideration of the factors entering into the design of water wheel runners, and of tests which have been made on various designs, shows that it is not possible to secure as high efficiencies, even though the operating conditions be the most favorable, for specific speeds which are higher or lower than the specific speeds between K = 40 and K = 50. Experiments have also shown that there is a certain best speed for each particular type of runner, which speed gives 100 per cent. power. At all other speeds, either higher or lower, the power is not so great. The variation of power for changes in speed, however, is different in magnitude for different types.

Fig. 9 shows this for two different runners, one where K = 45, the other where K = 75. In this diagram the best speed is shown at the centre ordinate as occuring at 100 per cent. full power, and it will be noted that as the speed is made higher or lower than this best speed, the power drops off for both types of runner. In the case of the runner K = 75, it drops off considerably more than for the type K = 45. For instance, an examination of the charts show that an increase in speed of a Type 2 runner, with K = 45, of 10 per cent. above the best speed, decreases the horse power 4 per cent. while a decrease of 10 per cent. from the best speed decreases the power about 2 per cent. For a runner with K = 75, the horse power is decreased 6 and 4 per cent. respectively.

In Fig. 10 is given a curve showing the relation between variation in head and equivalent variation in speed. This is really a graphical expression of the formula rev. per min. oc $\sqrt{H}$ or the equivalent expression rev. per min. = (a constant) $\sqrt{H}$. It will be noted by examining this chart that for a variation in head of 20 per cent. there is an equivalent speed variation of 10 per cent. For a variation in head of 40 per cent. there is an equivalent speed variation of nearly 20 per cent. This curve will be of use later on in our discussion.

With information such as the foregoing at hand, we should be able to select the best speeds, power, ratings, etc., for use in any given installation.

Number of Units in the Plant.—In order that a plant may work to best advantage on the load it has to carry, it must be designed to accommodate the characteristics of that load. In making this determination, a careful study should be made of the load curve and the load factor. There are also a number of other matters of importance entering into this particular subject; for instance, the question of whether or not the plant being designed is to operate alone or in parallel with other plants, whether there is to be a spare unit provided, etc. It is not intended to enter into any lengthy discussion of this subject at this time. Unless the purchaser has reliable information for arriving at a decision on the number of units to be used in the plant, it it advisable for him to secure the assistance of an engineer familiar with such subjects.

Size of Generators.—The generator should have a rated output approximately the same as the most economical capacity of the water wheel. It is assumed that an effort will be made to operate the generator as near as possible to its rating. It must be remembered that the most economical point of the wheel varies for different specific speeds. Even though the rev. per min. may not be determined and the specific speed not yet calculated, it can be at once found out from the curve that the maximum horse power of the wheel divided by the kw. rating of the generator should vary from 1.5 to 1.9. This is obtained by dividing the maximum horse power by the horse power at the most economical point and then again by 0.746 to reduce kw. rating. It may thus be said that the maximum horse power of the wheel divided by the kw. rating of the generator will vary from 1.5 to 1.9, depending upon the type of runner to be used. Manufacturers could, therefore, make up a tabulation of the value of this coefficient for their different types of runners. In the first approximation the value of this coefficient might be taken as 1.75, about the average value, and the kw. rating of the generator determined. Later on this could be corrected. The matter of overload should be kept in mind when this point is being worked out.

Standard Speed of Generators.—The electric manufacturing companies can supply tables of speeds for standard generators. Generators with frequencies of 25 and 60 cycles are the most common in use. It is not necessary to give such a table in this paper as it would be altogether too large if it covered all of the standards in use by the electric manufacturing companies. In such a table furnished the writer recently there are to be found for some of the more common sizes of generators met with in modern plants as many as 5 or 6 speeds standardized for each size. For instance, one company has made and is prepared to make a 175-kw. generator of water wheel type for 150, 180, 300, 514, and 600 rev. per min, and for full load voltages of 600 2,300 and 11,000-volts. Several speeds would be considered by the designer before making a choice, and the reasons governing the choice will now be considered.

What Speed of Unit is Based Upon.—The following elements enter into the selection of the speed of the unit: (a) head, (b) characteristic efficiency, (c) runner balancing, (d) speed regulation, (e) variation in head, (f) durability of design. We will discuss these points in order.

(a) Head.—The head is a most important factor in the selection of the speed. Low heads and attendant low

* A paper presented at the Pacific Coast Meeting of the American Institute of Electrical Engineers, Portland, Ore., April 16-20, 1912.

velocities permit of a design of bucket to handle large quantities of water. In such a runner, thin warped buckets of ample size and large openings can be used. These buckets are, relatively speaking, structurally weak. High heads and consequent high velocities make necessary a simple design of bucket, thicker material, and, therefore, relatively small quantities of water. Strength, therefore, must be carefully considered in determining the diameter and speed of a runner. In general it may be said that for proper strength and design, the following specific speeds may be used for any head below the maximum head given.

Specific Speed. K rev. per min.	Maximum Head. feet.	meters.
68 to 75	50	15
50 to 68	100	30
35 to 50	200	61
25 to 35	400	122
10 to 25	600	183

This tabulation is not by any means fixed and is merely given as a guide. If the specific speed figures out for any given head as greater than the values given above, two runners should be used. If two runners are used, the specific speed must again be figured out with a horse power one-half of that used before. If head were the only determining factor, the specific speed could be chosen from the above table and the rev. per min. calculated from the formula.

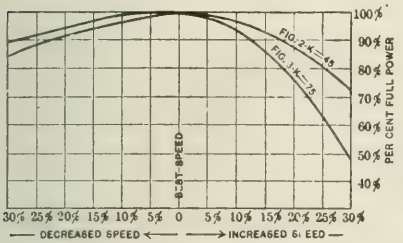

Fig. 9.—Effect on Power of Change of Speed, Based on Constant Head.

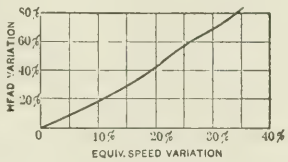

Fig. 10.
(See Fig. 9.)

(b) Characteristic Efficiency.—It has already been shown that different values of K result in a different efficiency characteristic. From our formula it is noted that specific speed varies with rev. per min., hence for any given horse power and head the rev. per min. fixes the specific speed, and the efficiency which is obtained from a runner with this specific speed both for full load and for partial loads. The particular speed characteristic desired, therefore, has much to do with selection of the speed of the runner.

(c) Balancing.—A single runner can be designed so as to balance thrust. This is sometimes desirable. With a single runner we have a lower specific speed and, therefore, consequent large diameter of runner. This should be considered by the designer and used where possible. The question of thrust does not enter into consideration with a pair of runners, as these are placed on a shaft as right and left-hand runners and the thrust of one runner is neutralized by that of the other. It is often found, however, that when a pair of runners is used, other conditions of the design must suffer and perhaps to the disadvantage of the installation. In making a proper selection of speed, therefore, the question of balancing is of importance.

(d) Speed Regulation.—Speed regulation is oftentimes the most important item in fixing the speed. The lower the speed the larger are the diameters and weights of the rotating element and, therefore, the greater flywheel effect of the unit. When the load on the unit is changed the speed varies directly with the flywheel effect. It is therefore often desirable to use a lower speed, fixing this speed by the degree of regulation desired. Extra flywheel effect can be obtained by the use of a flywheel, but this is generally undesirable and if possible should not be considered on account of the danger due to high pressures on bearings, etc.

(e) Variation in Head.—This is a common condition in low head plants. In hydroelectric plants the speed must be kept constant, even though the head does vary. In the case of pulp grinding mills, speed variation is not of so great importance.

We have already shown in Figs. 8 and 9 that different speeds have different characteristics of power and efficiency when the runners operate under heads other than the heads they were designed for, and lower speed than that given in some manufacturers' standard table of speed may oftentimes be used to advantage and might mean a considerable increase in the output of the plant. At the same time the initial cost may be greater and in such cases a proper balance between cost and benefits must be found.

To get a full conception of the effect of variable speed let us take an example:

Example.—A certain water plant has installed in it a water wheel runner of type No. 3, K = 75, which is designed to deliver 1,000 h.p. maximum at 200 rev. per min. when operating at 40-ft. (12 m.) head. This particular plant is so located, however, that the head varies due to floods, and at times the operating head drops down from 40 to 24 ft. (7 m.) The plant is a hydroelectric plant, and the generators driven by the water wheels require a constant speed of 200 rev. per min. in order to operate properly on the electric system connected to them. Let us investigate what will happen under these conditions. One of our fundamental formulas states that the horse power varies as $H^{3/2}$. Therefore, at 24-ft. (7-m.) head our 1,000-h.p. wheel will give $\frac{1{,}000}{\left(\frac{40}{24}\right)^{3/2}} = 465$ h.p. This calculation, however, is based on the assumption that we allow the wheel to run at the proper speed for 24-ft. (7-m.) head, which speed would be in accordance with the formula: rev. per min. oc $H^{1/2}$. Thus, $\frac{200}{\left(\frac{40}{24}\right)^{1/2}} = 155$ rev. per min.

Now, as a matter of fact, we do not want to allow this change in speed for the reason stated above, and as this is the case, we must sacrifice some of our power. If, therefore, we decrease the head from 40 to 24 ft. (12 m. to 7 m.) which is a drop in head of 16 ft. (5 m.) or a change of 40 per cent. in head, we will have, in accordance with the chart in Fig. 10, a corresponding speed variation of approximately 20 per cent

Referring now to Fig. 9 we note that for an increase of 20 per cent. in speed, there is a corresponding decrease in power for a Type 3 runner of 25 per cent. We would sacrifice, therefore, when operating at these changed conditions, 25 per cent. of the power which the runner operating at its best speed for this head possesses, that is, 25 per cent. of 465 h.p. or 115 h.p. We would have left, therefore, when operating the wheel under these changed conditions as brought about by flood, the difference between 465 h.p. and 115 h.p., or 350 h.p. If a runner of type No. 2 K= 45, should be installed in this plant instead of a runner of Type No. 3, it is readily seen from Fig. 9 that when operating under the changed conditions brought about by the flood, the loss in power, instead of being 25 per cent., would be but 12 per cent., which is a loss of 57.5 h.p. The power,

therefore, of a type No. 2 wheel, if installed in this plant, and operating under the altered conditions, would be 465 h.p. minus 57.5 h.p., or 407.5 h.p.

(f) Durability.—In high head installations particularly, pitting of the runner blades takes place, due to shock of water against the buckets, or high velocity, and the operation of the unit much of the time at other than the most economical point. This being the case, it is quite important to consider durability when making the selection of the proper speed of runners. Let us again consider the formula $v = 52\sqrt{H}\sqrt{\frac{\sin (A+B)}{\sin B \cos A}}$. If we select a value of B = 90 degrees the trigonometrical expression under the radical sign becomes unity, changing the formula into $v = 52\sqrt{H}$ which is the formula for discharge from a simple nozzle. It is found when a value of B = 90 degrees is selected that the pitting is reduced to a minimum. From the above deduction this would be expected.

In the foregoing discussion we have considered a large number of items which enter into the subject of water wheel design and have indicated the desirability of getting some good engineering advice when selecting a unit. We have not, by any means, covered all of the points which enter into this interesting subject, nor would it be possible to do so in the time at our disposal. It is not expected that in general the buyer should acquaint himself with all of the various formulas and curves which have been dwelt upon. It has been necessary, however, to review them in a brief manner in order to lead up to the recommendations to the purchaser selecting a water wheel unit.

Ceneral Design of Unit.—The conditions which must be met with in the particular plant where the installation is to be made determine the general make-up of the unit. Water wheels may have but a single runner, may have a pair of runners, or for low heads, four or even six runners to the unit. In some places a vertical design of unit is required, while in others horizontal units best suit the conditions in many instances; it is merely a matter of taste, but in most cases there are features which influence the selection of horizontal or vertical units.

When a pair of wheels is used, it must be determined whether an outward discharge or a bottom centre discharge is the more desirable. Both schemes are used, one involving a single draft tube, the other, two draft tubes.

When low heads are met with, open flumes are possible and a properly arranged open flume may take the place of the closed flume. In high head work it is, of course, necessary to use a closed flume.

The housing enclosing the runners may have various forms. For instance, it can be a scroll case design or a cylindrical design; it can be made out of cast iron, cast steel or steel plate or may even be formed in concrete. The scroll case has high economy on account of the water passages being designed so as to give a proper increase in velocity before the water enters the runners.

There are many other types of flumes, such as the cone shaped type. This type has ordinarily high economy, but has the disadvantage of a bearing which is not readily accessible.

Consideration must be given as to whether the inlet of the unit is to be beneath the floor line or above; the general question of accessibility of the various parts of the unit, the location of the governor, and many other points must be given attention. Racks of ample area must be provided at the intake in order that there may be low velocities through same and little loss of head. The pipe line must have careful consideration and proper velocities must be selected.

In plants with long pipe lines, the speed regulation and the consequent pressure variation is of great importance, as the latter has to do with the strength necessary and, therefore, the design of the pipe line. In some cases, pressure regulators are necessary. Again, surge tanks may be used. The draft tube must have proper attention and the tail-race be such as to give low velocities. If the tail-race is restricted, the total head is affected.

In order that the purchaser and water wheel manufacturer may have at hand when the wheel is being designed data covering all of the points which should enter into the design, it has been thought advisable to give a list of questions which should be filled out as completely as possible by the purchaser and sent to the manufacturing company for use when making his wheel.

Data to be Given to Water Wheel Manufacturer.

1. Number of units.
2. Horse power of water wheels.
3. Kw. of generator.
4. Total head.
5. Open flume or closed flume.
6. If closed flume, what is number of pipes?
7. What kind of pipe?—wooden stave, steel or concrete?
8. Diameter of pipes.
9. Effective head (unless design of all water passages to and from wheel is left to water wheel manufacturer).
10. Head water elevation.
11. Floor elevation.
12. Tail water elevation.
13. Head variable, if so, what is normal operating head?
14. If head is variable, what is the range of variation?
15. How important is power and economy at lowest head?
16. Speed of generator, if already decided.
17. If speed of generator is not decided, name speeds which seem to purchaser most desirable, and ask recommendations.
18. Flywheel effect of generator.
19. What speed regulation is desired for different load changes?
20. Will units run in parallel with other plants? If so, give general characteristics of such plants.
21. If running in parallel with other plants, can these plants be used to regulate the system?
22. What is the character of load factor?
23. What is the nature of water (silty or clear)?
24. What date shipment of material is desired?
25. Advise if it is expected that manufacturer shall furnish governor.
26. Give sketches of power plant site.
27. Give information as to what is to be expected in the way of guarantees.
28. Give any other information which you think would influence the design of the wheel.

It will not be attempted here to outline the specifications which should be made out to cover the purchase of the water wheel unit, but a list of data which should be supplied by the water wheel company is offered.

Data to be Supplied to Purchaser by Water Wheel Manufacturer.

1. A check of the calculation on effective head.
2. Horse power guarantee at normal head.
3. Guarantee at other heads, if head is variable.
4. Speed guarantee, including runaway speed.
5. Recommendation for best speed if same has not been determined.
6. Speed regulation guarantees.

7. Efficiency guarantees at full load, ¾ load and ½ load.

8. Point of greatest efficiency of wheel and value of same in per cent.

9. Efficiency guarantees for available head conditions.

10. If water wheel manufacturer furnishes governor, give information as to the type, make, power required to operate same, also what variation in speed will not be exceeded before the governor will begin to readjust gates to meet a change of load, either gradual or sudden.

In what time will governor completely open or close gates?

Within how many seconds will the speed of the unit be restored to normal?

11. Complete drawings showing machinery proposed.

12. Complete description of machinery proposed.

13. Guarantee of durability.

14. Guarantee of shipment.

Conclusion.—In submitting for your consideration the foregoing, I have endeavored to impress upon you the importance of giving careful attention to a number of principles which enter into the selection of a water wheel unit. It is quite possible that the ideas of the writer on a number of points which have entered into this discussion may not altogether agree with those entertained by others. He has, however, laid stress upon points which in practice he has found of value in selecting water wheels. It is hoped that the subject matter will form the basis of a beneficial discussion of this most interesting subject.

VISIT OF BRITISH CAPITALISTS.

A recent report from Ottawa states that arrangements have been completed for the visit to Canada of from 50 to 60 British capitalists, business men and manufacturers, representing, all told, something like two hundred millions. Conferences have taken place between Hon. George Foster and Mr. Leonard Palmer, of London, the originator of the trip. The party will include representatives of the London Chamber of Commence, several British Boards of Trade, Vickers, Limited, Birmingham Small Arms Co., Commill, Laird and Co., and other big British industries.

They will sail from Liverpool on the "Empress of Britain" on May 31st, and will arrive on June 6th at Quebec, where they will be officially welcomed to the Dominion. After a brief stay in the ancient capital they will proceed to the Maritime Provinces, where a week will be spent in inspecting the resources of that portion of the country. Arriving at Montreal about June 15th, they will afterwards proceed to Ottawa, where the visitors will be given an official welcome by the Dominion Government. They will subsequently visit Toronto and the chief points in Ontario, including Niagara and the Cobalt camp. Then, proceeding west, the party will make an extensive tour of the western provinces and of British Columbia. The visitors will again be in Montreal about July 19, and will sail for Liverpool, where they are due to arrive about July 27, after a tour of 42 days in Canada. The various Boards of Trade as well as the civic authorities throughout the Dominion have already taken steps towards giving the visitors a welcome.

The Quebec Harbor Commission has decided on building an elevator of one million bushels' capacity, of concrete and steel structure, with links that can be extended and developed so as to store two million bushels of grain, together with the construction of two piers on the Louise Embankment.

OIL-BURNING LOCOMOTIVES.*

By R. Godfrey Aston, of Rincón Antonio, Oax., Mexico.

The object of this paper is to give an account of liquid-fuel burning in the locomotives of the Tehuantepec National Railway, showing some of its advantages over coal, and giving a general description of facilities for handling and storing this fuel-oil, the methods of burning it, and a few results gained, which are taken from the monthly performance of locomotives. The author does not intend to deal fully with costs, &c., as it is too large a subject for so short a paper, but will confine himself to a more practical point of view.

The Tehuantepec Railway is a trans-continental line of standard gauge (4 ft. 8½ in.), 304 km. (189 miles) long, running across the Mexican Isthmus of Tehuantepec from the port of Puerto Mexico (Coatzacoalcos) on the Atlantic, to the port of Salina Cruz on the Pacific, with grades varying from level to 2.15 per cent., and abounding in curves up to 11 deg. 28 sec., or 100.10 metres radius, and where the speed of trains is limited to 24 km. (15 miles) per hour.

Storage Facilities.—All fuel-oil for the company is received at the terminal of Puerto Mexico, where the main storage tanks are situated; these comprise three cylindrical steel tanks, each composed of six tiers of steel plates riveted together and a light steel roof, with three manholes, and a ventilator in the middle, through which gases arising from the oil can escape. Two of these tanks are 95ft. in diameter and 37 ft. 6 in. deep, each with a capacity of 46,996 barrels of 42 U.S. gallons (35 British gallons).† The third tank is 92 ft. in diameter and 29 ft. 9 in. deep, and has a capacity of 35,138 U.S. barrels.

These tanks are all enclosed in separate earthen embankments and are connected together by an 8-in. pipe-line, which enters the tanks 1 ft. 6 in. from the bottom, this space being required for water, &c., settling out of the oil, and which can be drawn off through a 3-in. valve at the bottom of the tank. The pipe-line runs down to the wharf, where it is fitted with an 8-in. check-valve, and it is from there that vessels delivering cargoes of oil can pump straight into any tank, the two largest tanks being about 2 km. (1¼ miles) from the wharf. At convenient places in the pipe-line near to the round-house are stand-columns for filling engine-tanks, tank-cars, &c., and near the round-house is also a supply-tank of 28,000 U.S. gallons capacity, erected upon a structural steel frame, also used for giving oil to engines, &c.

The terminal of Salina Cruz is laid out in the same manner, except that there are only two storage-tanks, 95 ft. diameter and 37 ft. 6 in. deep, of 46,996 barrels capacity. The capacity of all these storage-tanks has been calculated out in U.S. barrels of 42 gallons for every 6 in. of depth, allowance being made for all internal stays, supports, &c. The fuel-oil is shipped from Puerto Mexico to the other fuel-stations in specially constructed double-truck steel-frame tank-cars of 6,600 U.S. gallons capacity, the gallons per inch of depth of these cars being known, so that the exact amount contained in each car can be credited to the station to which it is shipped.

Fuel-Oil.—The fuel-oil used by this company is purchased from the Texas Company, of Port Arthur, Texas, at

* Paper read before the Institution of Mechanical Engineers.

† 1 U.S. gallon = 231 cub. in. 1 British gallon = 277.27 cub. in. U.S. gallon = 5/6 British Imperial gallon. The value of the Mexican dollar is assumed throughout this paper to be 2s.

about 97½ cents gold per barrel of 42 U.S. gallons, delivered at Puerto Mexico and pumped into the railway company's tanks by the delivering vessel. This fuel-oil is generally delivered in tank steamers, sometimes towing barges, which come right up alongside the railway company's wharf; the coupling between the vessel and the company's land-pipe line is made with a flexible rubber or steel hose, which is supplied by the vessel.

This fuel-oil is quite thin and flows readily through pipes of any diameter; it is sometimes nearly black in color, and sometimes a dark brown with a green fluorescence. The railway company stipulates in its contracts with the Texas Company that the flash-point (closed) shall not be under 110 deg. Fahr., as a lower flash-point than this is liable to be dangerous, on account of the volatile gases and fumes which arise from the oil at comparatively low temperatures, and the author has seen the oil catch fire from a torch which was some 10 ft. or 12 ft. away from it. Some oils may be used in the crude state as fuel, while others have to be passed through the refinery; after the lighter oils, &c., have been taken off, the by-product or residuum is used in a satisfactory manner as fuel, and as such has been, and is, used in Mexico. Fuel-oil contains no power of spontaneous combustion, and, unlike coal, does not deteriorate if stored in tanks or reservoirs.

The specific gravity of this oil varies from 0.790 to about 0.942, and its weight per U.S. gallon from 6.4 lb. to 7.75 lb. The British thermal units vary from 17,000 to 20,000, the average being from 19,500 to 19,800, and between this and the best steam coal there is a very great difference. The analysis of two samples of the oil as used by this company for fuel is as follows:—

	No. 1.	No. 2.
Specific gravity at 60 deg. Fahr.	0.931	0.881
Baume Gravity at 60 deg. Fahr.	20.5 deg.	29 deg.
Flash-point (closed)	130 deg. F.	135 deg. F.
Flash-point (open)	160 "	160 "
Fire test	220 deg. Fahr.	224 deg. Fahr.
Setting point	3 "	20 "
Viscosity at 100 deg. F.	200 seconds (Redwood)	78 seconds (Redwood)
Sulphur	0.77 per cent.	0.26 per cent.
Calorific value	10,688 calories	11,000 calories
Color	Dark brown	Dark brown
Water and dirt	1 per cent.	0.25 per cent.

The standard temperature for the measurement of fuel-oil is 60 deg. Fahr., and expansion is allowed for at the rate of 1 per cent. for every 20 deg. Fahr. increase in temperature above 60 deg. Fahr., and contraction at the same rate for decrease in temperature below 60 deg. Fahr.

Locomotives.—The locomotives in use on this road are of the Baldwin consolidation type, the main dimensions of which are:—

Cylinders	20 in. by 26 in.
Wheel (drivers)	53 in. diameter on tread
Fire-box	Length inside, 108in.; width inside, 33½ in.
Flues	239 of 2 in. outside diameter
Grate area	24.94 sq. ft.
Heating surface	Fire-box, 147 sq. ft.; flues, 1,700 sq. ft. Total, 1,847 sq. ft.
Boiler pressure	170 lb. per sq. in.

The oil-tank is fitted into the coal-space of the tender, and its contents calculated for every ½ in. of depth. Most oil-tanks have a capacity of 2,000 gallons, and the oil is fed from the tank to the burner or atomizer through suitable connections and flexible brass ball-joints.

Fire-Box Arrangement.—The company's practice, after trying various types of burners and atomizers, is to use what is called a "front-end burner," that is, the burner-mouth points towards the back of the fire-box or fire-box door-plate; the burner is placed, in a 9-ft. fire-box, 4 ft. 2 in. from the flue-sheet, the flame playing against a brick wall built up to the level of the fire-box door opening. Between this brick wall and the fire-box back-plate is a 4 in. air-space extending the whole width of the fire-box and right up to the top of the brick wall. Brick walls are built up on each side of the fire-box from the height of the brick wall at the back, gradually sloping downwards; the floor of the grate or ash-pan is laid all over with fire-brick. No brick arch or baffle-plate is used.

As mentioned in the preceding paragraph, the burner is placed 4 ft. 2 in. from the flue-sheet, and midway between the sides of the fire-box, so that both in front and behind the burner or atomizer there is a flat bricked-over area of fire-grate; and as the burner is placed parallel to the lower grate, there is a 4-in. space between the front and back grates, this 4-in. space being left open to admit air, extending from one side of the fire-box to the other.

Brickwork.—This should be of the very best material and workmanship, as it is subject to a much greater heat than from a coal fire; if this is not done, the walls will not stand, and engine failures will occur; moreover, the failure of only one brick will perhaps necessitate new brickwork throughout, thus needlessly running up expenses. There is no reason why the brickwork should not stand from four to six months, and perhaps longer, if due care be taken from the start.

A good brick should contain about 80 to 85 per cent. of silica and from 20 to 15 per cent. of alumina, and should be as free as possible from alkalis, which cause fluxing. A good brick becomes surface-glazed though remaining rough and porous; it should be perfectly dry when built up in a fire-box, otherwise the heat will cause it to crack; if possible, the fire-bricks should be fired at a temperature as high as that to which they will be exposed when in use.

Burner or Atomizer.—There are many and various kinds of hydro-carbon burners, and after a trial of various types, including the Baldwin and "Best" burners, this company is using with considerable success a burner which is made in their own shops, and which is really an inverted "Best" burner. It is a simple device, which allows the oil to fall from an orifice 3 in. wide by 9/16 in. deep over the top of a flat steam-jet 3 in. wide and 1/32 in. deep, the steam picking up the oil and sending it into the fire-box in the form of a spray; the underneath jet of steam delivers the spray of oil at an angle so that it strikes the brick wall in the middle, instead of shooting out from the burner parallel with the bottom of the ash-pan. This burner may be called an outside atomizer, and although it is in general use, it has its drawbacks; but it has been found to be more efficient than any other they have used.

The most essential points about a burner or atomizer are:—

1. Its atomizing capacity. All fuel-oil is heavy, and will burn in the form of a vapor or spray only when mixed with air. The object should be to fill the fire-box with a soft and voluminous flame, and not to impinge it in any one place.

2. Its facility for keeping clean and free from clogging.

3. Its adjustability in giving the right direction to the flame or spray, and regulating the proper proportion of oil and the agent, either steam or air, used for atomizing.

A burner which will vaporize or atomize the oil at the point of expansion of the agent used for that purpose, and

which is easily handled, and which will atomize the greatest amount of fuel with the least possible energy, is the highest and most efficient that can be designed. On this railway steam is used as the atomizing agent, because, after various experiments, it was found to be superior to air. The steam to a very great extent heats the oil as it flows into the burner before delivery in the form of a vapor spray. The flame from the burner should not be too long, or it will pass into the flues and become extinguished. Gases which are only partly consumed will re-light in the smoke-box.

Lighting up an Oil-Burning Engine.—In each round-house of this company is a stationary boiler, always in steam, used for the washout and other pumps, as well as for lighting up dead engines. From this boiler is laid a 2-in. steam-line to points between each engine road or stall. From there a connection can be made to a locomotive through a three-way cock or T-piece in the steam-pipe leading from the steam-stand on top of the fire-box to the burner; by use of this steam the burner can be started and kept going until the boiler has generated enough steam to keep the burner going itself. A piece of oily waste is lighted and thrown into the fire-box just in front of the burner from which the spray ignites. Connections can be made to any other engine all ready in steam should the stationary boiler not be available for any reason.

Firing and Cleaning Flues on Road.—With an oil-burning engine there is always a fire of equal intensity and one which never gets dirty, so that good steaming is practically ensured. It is a popular idea that it is a very easy matter to fire an oil-burning engine, but this is not the case, as both skill and care are required, so that the author thinks it best to lay down a few of the most important rules:—

1. See that the oil-tank is full, and if heaters are used, that they are in operation, and that the temperature of the oil is as it should be.

2. See that the sand-box on the foot-plate is full, and that the scoop is in its place.

3. Before starting the fire see if the temperature of the fire-box is below igniting point, which is a dull red, and if so, open dampers (if used), start the blower, and open the atomizer-valve fairly hard; then put a piece of saturated oily waste on the bottom of the grate after setting it alight, close the dampers (if used) and fire-box door, and turn on the oil very light. When the oil has ignited, reduce the blower and atomizer to a light feed, also the oil until the chimney is quite clear of smoke.

4. See that the fire is burning brightly, and that there is no oil on the bottom of the pan, also that the brickwork is in good condition, and that no bricks or any other obstructions are on the bottom of the grate or pan so as to obstruct the flame or jet on its way from the burner to the brick wall.

5. As regards cleaning flues on road, it is best to sand frequently if the engine is being worked hard—say every 15 km. or 20 km. (9 or 12½ miles); but if the engine is being worked light, every 50 km. or 60 km. (31 or 37 miles) will be sufficient.

6. Having attained a fair rate of speed, fill the scoop with about a quart of sand, close dampers (if used), and put reverse-lever near full stroke, then open regulator wide, insert the end of the scoop in the round hole in the fire-box door, and allow the sand to be drawn out of the scoop through the fire-box and flues and out of the chimney; sanding is best done when the engine is working hard up a grade.

7. Black smoke shows incomplete combustion, and should never be allowed to be emitted from the chimney, as it only fills up the flues with carbon, besides being a non-conductor of heat, and it is also a great waste of fuel. If a bluish-colored smoke or fumes are seen coming from the chimney, it is a sign that the burner is cut down too fine.

8. When putting out the fire the oil-valve should always be closed first, then the atomizer-valve (in their case steam), then the blower. The oil-valve is always the last to be turned on and the first to be turned off.

9. Never go near an open tank with a lighted lamp or torch, as at any time an explosion may occur, especially if the oil used has a low flash-point.

Round-House or Shed Work.—An oil-burning engine has a great many advantages over a coal-burner, but this is specially noticed in the round-house or shed when squaring up an engine after a day's run; there are no fires to be raked out, no flues or smoke-box to be cleaned (the smoke-box door of an oil-burning engine need be opened only once every three or four months for cleaning purposes); there is no coal to be sacked, weighed, or otherwise handled, and oil-burning engines do not carry fire-rakes, prickers, flue-brushes, shovels, or picks, so that all these things, besides other minor details, represent a great saving in engine equipment.

Among other advantages are the rapidity with which steam can be raised, and the facility with which the boiler can be forced when greater calls are made; the author has in a special case of necessity raised steam in a dead engine to a pressure of 130 lb. per sq. in. in 50 minutes from cold water, without any serious effects on the boiler, whereas in in a coal-burner from 2 to 3½ hours is needed to raise steam if no jet from a live engine is used.

Another very great advantage is in switching, or shunting, or standing pilot, when engines frequently have to stand in steam for hours at a time. The burner can then be cut down or extinguished, thus effecting a great saving in fuel, as an engine will always retain a sufficient amount of steam to start the burner or atomizer again; and any danger of the fire-box or crown-sheet being injured through the water getting too low is entirely obviated. The heat lost while standing is the same whether coal-fired or oil-fired.

Effects of Oil-Burning on Fire-Box, Flues, &c.—Oil-burning is no more injurious to a fire-box or flues, &c., if ordinary care be used, than coal-burning; in fact, from the author's experience, it is not so hard on a fire-box as coal-burning, for it is quite noticeable in the fire-boxes of coal-burning engines that stay-heads, plate-edges, flue-ends, and crown bolt-heads show signs of wear, corrosion, or burning, but in their oldest oil-burning engine not any of these signs are noticeable, everything being clean and in good condition.

This company uses steel boxes with wrought-iron tubes and copper ferrules. A set of tubes will last, and remain perfectly tight, from 2½ to 3½ years, when they may have to be taken out to be re-ended; some of the engines are working to-day with tubes over four years old, many of which are as tight as they were on the day they were put in. Some of the wrought-iron tubes are being replaced by mild steel, because, after the holes in the tube-sheet get worn, tubes of steel stand the expanding better; but at present those that are in service have not been in use long enough for one to form an opinion of them as compared with wrought iron.

Some people are of the opinion that more than 2 per cent. of sulphur in fuel-oil is injurious to the fire-box, but as the amount of sulphur in the Texas oil the company has been using is below 0.75 per cent., no ill-effects have been noticed; but as there are coals which show as high as 3.5 per cent. of sulphur, the author does not see why sulphur should be more injurious in oil than in coal.

Engine Performance.—Although the engine tonnage has practically doubled since 1908, the author gives the following statistics for each month from January, 1907, to August, 1911:—

(1) Cost of fuel-oil per barrel of 42 gallons (Mexican currency);

(2) Cost per kilometre for fuel (Mexican currency); and

(3) Kilometres run per barrel of oil;

but it must be understood that since about the middle of 1909 all engines are loaded down to their capacity, single trains averaging 750 to 800 tons behind the draw-bar. As the road-bed is by no means level, helper engines are used over certain sections where the grades are long and heavy, so that this will explain the decrease in kilometres run per barrel of oil between 1908, 1909, 1910, 1911, as the tonnage per engine has been increased to the maximum.

Oil-Fuel. Monthly Averages.

During.	Cost of Oil per Barrel.		Cost for Fuel.		Distance Run per Barrel.	
	Dollars (Mexican).	Shillings.	Cents per Km.	Pence per Mile.	Km.	Miles.
1907	2.585	5.17	28.476	10.99	9.546	5.928
1908	2.357	5.91	27.151	10.48	11.04	6.855
1909	2.502	5.01	25.19	9.73	9.999	6.209
1910	2.356	4.71	25.02	9.66	9.41	5.843
1911 (8 months).	1.990	3.98	22.23	8.58	8.89	5.520

The cost of fuel-oil per barrel of 42 U.S. gallons (231 cub. in.) as charged out every month is made up of the following items, and also depends upon whether there is any shortage or overage when the inventory is taken at midnight on the last day of each month; this accounts for the variation in prices:—

1. Price of oil per barrel f.o.b. in ships' tanks at delivering port (Puerto Mexico).

2. Commission to purchasing agents in United States.

3. Consular invoices.

4. Inspection fees for inspecting cargo in ships' tanks at shipping point.

5. Stamps.

Items 2, 3, and 4 only refer to oil purchased out of Mexico.

Based on tests which have been made, the company reckons 3½ barrels, or 147 U.S. gallons, of oil as being equal to 1 ton of coal or 1,000 kg., or 2,204 lb. or 3½ barrels of oil equal one unit of fuel.

The author is unable at this time to give any reliable data of fuel consumption on a tonnage basis, as no records are kept of the company's freight hauled over the road, although it is considerable; but the average loaded passenger and freight cars hauled 1 kilometre per unit of fuel from January 1 to December 31, 1910, was 330.89, and from January 1 to June 30, 1911, 333.60. The average loading weight of freight-cars is approximately 30 tons.

In August this year (1911) the company received the first cargo of a native or Mexican fuel-oil, under a contract with the Campania Mexicana de Petroleo, El Aguila, S.A., at a price of 1.75 dols. (Mexican) (3s. 6d.) per barrel of 42 U.S. gallons delivered into railway company's tanks at Puerto Mexico. This oil, which is used in its crude state as fuel, is jet black in color, thick, and has a heavy asphalt base, and although the company has not used it sufficiently long to be able to compare it with the Texas oil, it may be of interest to state a few of the difficulties met with when first they began to use it.

As this oil is thicker than Texas oil, heaters have to be used in the engine-tanks, but it has been found that if this oil is heated up to about 150 deg. Fahr. (which can be done with Texas oil), great difficulty is experienced in getting the burner spray to light, and the oil settled very thickly at the bottom of the tank; it would not run through the pipes to the burner, and could only be burned effectively by mixing a fresh supply of oil with it. In order to burn this Mexican native oil successfully, it requires to be only just warmed. When using this, a large piece of carbon or coke-like substance is formed in the fire-box, and grows up from the bottom of the pan or grate directly under the burner-mouth. This may vary from 6 in. by 4 in. by 4 in. to 12 in. by 10 in. by 8 in. in size, growing up in such a manner as almost to smother the burner-mouth. The analysis of this substance is as follows:—

	Per cent.
Ash	1.25
Sulphur	7.89
Carbon	90.86
Asphalt	nil

It shows to a certain extent, that there is incomplete combustion, which can be remedied by admitting more air; but this cannot very well be done without affecting the steaming qualities of the engines. However, by raising the burner slightly, these lumps of carbon have decreased in size, and it is hoped eventually to adjust things in such a manner as to prevent their forming at all.

The analysis of two cargoes of this Mexican crude fuel-oil is as follows:—

	No. 1.	No. 2.
Specific gravity at 60 deg. Fahr.	0.944	0.942
Baume gravity at 60 deg. Fahr.	18.4 deg.	18.8 deg.
Flash-point (closed)	78 deg. Fahr.	102 deg. Fahr.
Flash-point (open)	104 "	120 "
Fire test	165 "	180 "
Viscosity at 100 deg. Fahr.	1080 seconds (Redwood)	920 seconds (Redwood)
Sulphur	3.44 per cent.	3.35 per cent.
Calorific value	10,971 calories	10,610 calories
Color	Black	Black
Water	Nil	0.5 per cent.
Asphalt	—	37 "
Carbon (coke)	—	12 "

It may be explained that the 37 per cent. asphalt is obtained by distilling off the distillates from the crude until only 37 per cent. residue is left, which consists of asphalt. The 12 per cent. coke is obtained by distilling this 37 per cent. down to 12 per cent. residue (on the crude); so that if they get 37 per cent. asphalt, they do not get the 12 per cent. coke; and if they get the 12 per cent. coke, they do not get the 37 per cent. asphalt.

The author regrets that at this time he is unable to go deeper into this subject, but he hopes that what little information he has been able to give with regard to oil-fuel burning in the Tehuantepec locomotives will be of interest to others working in the same direction.

The Port Colborne and St. Lawrence Navigation Co., Limited, has purchased the SS. "Algonquin" and "Cataract" as the nucleus for a new lake line of wheat and flour carriers. The former will take flour, for which her capacity is 2,700 tons, from the Maple Leaf milling plant at Port Colborne to Montreal. The "Cataract" will be used, for a time at least, in Montreal as a barge. We understand more boats will be built or purchased. This enterprise is looked upon as the carrying out of Mr. Hedley Shaw's intimation at the time of the opening of the big mill at Port Colborne that the Maple Leaf Flour Milling Co. might do well to establish its own line of boats, owing to the discrimination in rates made by the railways against shipments of flour compared with wheat. The management of the navigation company is largely identical with that of the milling company, Hedley Shaw being president, John Carrick secretary, and Cawthra Mulock, W. D. Robertson, C. W. Band and E. H. Laschinger being directors.

CHICAGO CANAL WATER DIVERSION.

The Great Lakes, which constitute the mose extensive navigable inland waterway in the world, have already had their levels permanently lowered to an extent which has resulted in serious loss to navigation and other interests. These changes in levels have occurred because waters which under natural conditions, would have reached the sea by way of the St. Lawrence River, have, instead, been diverted through an artificially constructed channel at Chicago, and, thereby, made to reach the sea by way of the Mississippi valley.

This loss in levels is a matter of national concern both in the Dominion of Canada and in the United States. As it is one of momentous importance to citizens of both countries, an intelligent understanding should be had of the facts relating to the whole matter. The Department of Marine and Fisheries of Canada has sent out a brochure entitled "Papers Relating to the Application of the Sanitary District of Chicago for Permission to Divert 10,000 cu. ft. per sec." A short abstract of the pamphlet is given here.

The need for conserving the integrity of the levels of the Great Lakes has long been appreciated and, in 1909, was made the subject of treaty between Great Britain and the United States. This treaty, known as the Boundary Waters Treaty, provides that no diversion from the boundary waters between Canada and the United States shall be made without the express authority of the governments of both countries, and corresponding provision is also made in the treaty respecting the diversion of other waters which materially affect the levels or flow of boundary waters. The present diversion of water through the Mississippi Valley, is one which materially affects the level and flow of boundary waters and, consequently, has become a subject for international consideration.

The diversion under discussion, had its origin in the sanitary needs of the city of Chicago. Chicago was confronted with the urgent necessity of disposing of her sewage in a manner that would prevent contamination of her water supply.

Two sluggish streams, the North branch and the South branch of the Chicago River flow through the city approximately parallel to the shore of Lake Michigan, to the main Chicago River which—since the diversion—flows westward from Lake Michigan. For many years, the sewage of the city was discharged into these streams, and, at least as early as 1860, the offensive condition of the South branch attracted official attention. The first complaints arose, not on account of contamination of the water supply, but on account of the offensive odor. In 1862, high water in the river, and lowering of the lake level by wind, resulted in arousing complaints respecting the foul smell and taste of the water supply.

In 1871, the situation was partly relieved by cutting down the summit level of the Illinois and Michigan canal—connecting the Chicago and Desplaines Rivers—and drawing the water for the canal from Lake Michigan. Later, it was found necessary to install pumping machinery, at Bridgeport, to maintain a current westward through the South branch and the Illinois and Michigan Canal. In 1874-80, another pumping plant was constructed to pump water from the lake, through the Fullerton Avenue conduit, into the upper waters of the North branch.

In 1880, after twenty-five years of struggling to get rid of her sewage and prevent contamination of her water supply Chicago was still looking for some means of purifying the river from its filth, and preventing a repetition of the great epidemics of 1848 and 1854, which had led to the construction of the first system of sewers.

To meet these conditions, Chicago, in 1889, decided to adopt an extensive sewage scheme employing what is known as the dilution method. This method was selected because it was believed that, if sufficient water could be readily and cheaply obtained, this method would be an economical one for Chicago. The dilution method consists essentially of diluting sewage effluent with sufficient water to render it inoffensive. In the case of the Sanitary District of Chicago, this proportion has been established by a State law which fixes it at one cubic foot of water per second for each 300 of population. On this basis, a population of 3,000,000 would require 10,000 cubic feet per second—an enormous amount of water and comparable to the mean quantity passing over the American fall at Niagara. Lake Michigan—an integral part of the Great Lakes system—and practically a unit with Lake Huron and Georgian Bay—afforded a possible source of supply and was tapped by Chicago.

A corporation, known as the Sanitary District of Chicago, was formed under a special Act of the State of Illinois, and empowered to undertake the construction and operation of the works necessary for the new projects. The enabling Act, entitled "An Act to create sanitary districts and to remove obstructions in the Desplaines and Illinois Rivers," was passed May 29, 1889, and came in force July 1st of the same year. The Sanitary District comprises an area of 358 square miles.

One of the first works to be constructed was a large artificial channel, known as the Chicago Drainage Canal, extending from Robey Street in Chicago, to Lockport, Ill., a distance of 32 miles. By means of this channel, water from Lake Michigan flows westward through the Chicago River—whose flow has been reversed—to the canal, and is discharged into the Desplaines River at Lockport. The canal was designed to carry 10,000 cubic feet of water per second, but was constructed to carry 14,000 c.f.s.

The canal was opened on January 17, 1900. Water from Lake Michigan then flowed through Chicago by way of the Sanitary canal into the Mississippi. As a high-water cycle in the Great Lakes followed the diversion, the injurious effects were not, at first, apparent. In 1909, a low-water cycle commenced and, in 1911, the level was only a few inches above the level of 1895—which, with the exception of 1819, is the lowest water ever recorded. The knowledge that a part of the loss then experienced, was due to the diversion at Chicago, effectually aroused navigation and the allied interests who were thus injuriously affected by the selfishness of Chicago.

The United States Secretary of War is vested with jurisdiction over, and discretionary powers appertaining to, the navigable waters of the United States. As the new flowage of water through the Chicago River affected navigation at the port of Chicago, it became necessary for the Sanitary District to apply to him for permission to divert the waters it proposed to use. The secretary authorized the diversion of a certain quantity of water and, after subsequent modifications, a permit was issued, fixing the amount authorized for diversion at 4,167 cubic feet per second. The Sanitary District, however, did not confine its use of water to the quantity authorized by the Secretary of War. A special board of engineers, under the chairmanship of Brig. Gen. W. H. Bixby, chief of engineers, was appointed to report upon the effect upon navigation of diversion at Chicago. The special board reported that the Sanitary District was diverting some 7,000 cubic feet of water per second, thus exceeding the authorized amount by 3,000 c.f.s.

It was proposed, in connection with the Chicago drainage canal, to construct a navigable waterway from Chicago,

by way of the Mississippi Valley, to the Gulf of Mexico. General Bixby has reported that 1,000 cubic feet of water per second would be ample for purposes of navigation.

A large amount of power can be developed from waters diverted by the drainage canal, and along the course of the proposed navigation route. The development, and sale, of this power would create a large revenue, and, in connection with this project, the Sanitary District and other interested parties, have entertained the hope, and expressed the expectation, that profits derived from the sale of hydro-electric energy, developed by means of waters diverted through the canal, would meet the whole expenditure on the Lakes-to-the-Gulf Deep Waterway.

It will be recognized, therefore, that this development of cheap power, coupled with the method of sewage disposal, has been a very strong incentive for Chicago interests to obtain all the water possible.

On the 5th February, 1912, the Sanitary District requested permission from the Secretary of War "to withdraw from Lake Michigan through the Chicago and Calumet Rivers—not to exceed 10,000 cubic feet of water per second". The Government of Canada was notified that the Hon. Henry L. Stimson, U.S. Secretary of War, would hold a hearing at which those interested might make statements relating to the effect which the proposed increased diversion of water at Chicago would have upon their respective interests. In accordance with this notification, the Hon. J. D. Hazen, Minister of Marine and Fisheries, Canada, appointed a special committee to prepare a case on behalf of the Dominion of Canada. This committee, consisting of Messrs. Daniel Mullin, K.C., A. St. Laurent, W. J. Stewart, V. W. Forneret and John Kennedy, was appointed by Order in Council dated March 27th, 1912. The report and recommendations of this special committee are embodied in the brief and counter-brief which have been submitted to the U.S. Secretary of War on behalf of Canada.

At the first hearing, held at Washington on February 28, 1912, representations for, and against, the application were made by citizens of the United States. A second hearing was held, also at Washington, before the Secretary of War, on March 27, 1912, when protests were made on behalf of the Government of Canada, the Commission of Conservation, the Dominion Marine Association, the Montreal Board of Trade, the Montreal Harbor Commission, the Toronto Harbor Commission and others.

A request was made on behalf of the Government of Canada that the application of the Sanitary District of Chicago to increase its diversion from Lake Michigan be not granted and, that any abstraction of water from Lake Michigan be limited to such quantity as shall not injuriously affect navigation and other interests on the Canadian side of the boundary.

After the hearing of March 27, 1912, the Secretary of War announced that seven days would be allowed the trustees of the Sanitary District to file their brief—the Dominion of Canada to file its counter-brief, not later than April 16th.

The argument for Canada, together with the brief for Canada, and the brief of Mr. J. C. Williams, counsel on behalf of the trustees of the Sanitary District of Chicago, and also the counter-brief for Canada, all as submitted at the respective hearings, are given below in full. The memoranda and statements made by various organizations represented at the hearings, including that of the Commission of Conservation of Canada, are also published herewith.

As a result of carefully weighing all the testimony of the navigation and other interests which have been adversely affected by the lowering of the levels of the Great Lakes, and the testimony adduced before the Secretary of War, and, also, the other available data bearing on the subject, the special committee appointed by the government of Canada unanimously reached the following conclusions:

(1) That there is no imperative necessity for such a large diversion of water from Lake Michigan for sanitary purposes, as is requested in the application.

(2) That the historical facts presented in this brief show conclusively that the sanitary canal can not be considered as the outgrowth and development of a scheme which has received recognition by the United States government, or that of the Dominion of Canada.

(3) That the claim that the Sanitary District is entitled, as a matter of right, to the use of so much of the waters of Lake Michigan as may be necessary for sanitary and domestic purposes, cannot be entertained in so far as it relates to the extraordinary and wasteful use proposed.

(4) It has been shown that very substantial injuries have been made, and are being suffered by navigation interests. Fears for future and more extensive damages, by reason of increased diversion, are exceedingly well founded, and justify the demand that some improved method of sewage disposal, which shall not require the abstraction of any considerable quantity of water from Lake Michigan nor the diversion of other outlets of water which would naturally flow into it, be adopted.

(5) That the Dominion of Canada has the right to a voice in the disposition of the waters of Lake Michigan for sanitary purposes in so far as such diversion injuriously affects navigation, because her citizens are accorded, by treaty, the right of free navigation in that lake, and, in that no diversion can be made without injuriously affecting her harbors, channels and canals.

(6) It having been shown that the sewage of Chicago can be so treated and disposed of by other means than the present dilution methods, by which great quantities of water are withdrawn from Lake Michigan and discharged through the Drainage canal into the Illinois River, it is contended on behalf of Canada, that the abstraction of water from Lake Michigan shall be limited to such quantity as shall not injuriously affect navigation interests on the Canadian side of the boundary, and, that such limitations shall take effect at the end of such time, as, in your judgment, may be reasonably necessary for the Sanitary District to instal, and put into use, the works which may be required for disposing of the sewage by other means than by the dilution method now in use.

(7) That, in view of the fact that the Sanitary District claims that permits hitherto issued deal only with the flow through the lower portion of the Chicago River, and that it has the right to take any amount of water, without permission, through the canal, provided it is supplied through other feeders, it is respectfully requested that all permits be only for such limited quantity of water as shall not injuriously affect navigation on the lakes and the St. Lawrence River, and be so worded as to state the total quantity which the Sanitary District of Chicago may be permitted to withdraw for domestic and sanitary purposes from the drainage basin of Lake Michigan.

We feel confident that the interests of humanity at Chicago, and the levels of the Great Lakes, and of the St. Lawrence River, can best be protected by the installation of a modern system of sewage disposal, rather than by using a method which has been shown to be injurious to the navigation and commerce of both nations, and, further, that the interests of the public generally will, thus, be protected and their welfare promoted.

The Canadian Engineer

ESTABLISHED 1893.

ISSUED WEEKLY in the interests of the CIVIL, MECHANICAL, STRUCTURAL, ELECTRICAL, MARINE AND MINING ENGINEER, THE SURVEYOR, THE MANUFACTURER, AND THE CONTRACTOR.

Managing Director: JAMES J. SALMOND.
Managing Editor: T. H. HOGG, B.A.Sc.
Advertising Manager: A. E. JENNINGS.

Present Terms of Subscription, payable in advance

THE APPOINTMENT OF A HEALTH COMMISSIONER.

"A vacancy will soon exist in the position of chairman of the Board of Health of the city of Boston.

The duties of the chairman and his two associates are various and responsible. They embrace the control of contagious diseases, including bacteriological tests, disinfection, and preventive measures; the inspection of milk, vinegar, provisions, tenements, slaughter houses, stables and occupations and conditions dangerous to health; the medical inspection of the schools, containing more than 100,000 pupils; the management of a smallpox hospital and a quarantine station; the control of convenience stations throughout the city; the compilation and publication of vital statistics, and other miscellaneous duties. The department has over two hundred employees.

The mayor will consider applications from physicians, sanitary engineers, or other persons experienced in this field, who are American citizens."

Attention is called to the last paragraph of the above. Applications for the position of Health Commissioner for the city of Boston are being invited, and the above is clipped from the notice calling for applications. It is nearly time for our Canadian municipalities, when openings in civic positions occur, to include a paragraph similar to the above, with the change of "Canadian" for "American." In many municipal appointments made recently in our Canadian cities foreign engineers have received the positions. We have stated before in these columns our feeling that just as able men can be secured from the ranks of the Canadian engineering profession as elsewhere. Evidently, our neighbors across the line feel likewise concerning their own appointments, and have taken measures to ensure the appointment of citizens of the country. The sooner their example is followed in this matter, the better it will be for both the cities concerned and the engineering profession.

THE CONSULTING ENGINEER AND THE MANUFACTURER.

Of late years a practice has prevailed among contractors and manufacturing establishments of gratuitously preparing plans, furnishing estimates and giving advice on engineering work. This has been the cause of considerable adverse comment on the part of the engineer, for it interferes with his legitimate practice. At the last annual meeting of the American Institute of Consulting Engineers a discussion of this practice arose, and the consensus of opinion was that something should be done to stop it, as it was certainly unfair and detrimental, not only to the engineer, but also to the manufacturer and contractor. A number of interesting points were brought out during the discussion. Mr. C. C. Schneider stated that a few years ago, in tendering on steel work, the prevailing practice of making designs on speculation had it demoralizing influence, which did not seem to be sufficiently appreciated by purchasers of structural work, they being led to believe that the contractor did this work gratuitously. A moment's reflection, however, will show the fallacy of such an assump-

tion. The fact is that the manufacturer has to pay for making designs, not only once, but many times over, as only once in a number of cases is he the successful bidder. This extra expense must be paid by the purchaser. Now, however, it is becoming more and more the practice to let contracts for bridges and other structures on designs prepared by engineers employed by the purchaser.

Nevertheless, it is true that a great deal of work is done by the manufacturer which should logically come to the consulting and constructing engineer. The result is that the actual purchaser of the company's product is compelled to pay the expense of investigating other people's projects which are never carried out. At the present time the reinforced concrete practice is in about the same condition as that of structural steel work some years ago. It will only be by the co-operation of the engineering profession that this condition of affairs can be ameliorated. It was suggested at the meeting mentioned above that the different engineering societies whose members undertake consulting work should adopt a schedule of minimum charges, and that the companies manufacturing apparatus, in furnishing estimates, plans and specifications should regard themselves as consulting engineers, and invariably should exact for the service rendered at least the minimum charge recommended. This would, no doubt, help to kill the practice. It is to be hoped that some concerted movement will be taken with regard to this matter.

SELECTION OF A WATER-WHEEL.

At various times we have referred to the increased precision now obtained by the water-power engineer in the design and installation of water-power development. A number of factors have contributed towards this result. One of the most important of these factors is that more thought is being given to the application of precise methods in selecting the water-wheel unit. By a gradual process of development the water-wheels themselves have been brought to a very high state of efficiency for operation under various conditions of installation. Theory has begun to play a large part in the design of units for special conditions of head and amount of water, until now a highly specialized branch of engineering service has been reached.

With the more general use of electric power and the perfection of high voltage of transmission, many developments of Hydro-Electric power have become possible. These include very low-head plants and very high-head plants, with a wide range in the quantity of water available. Regulation demands are becoming more rigid. Expensive storage dams, with large reservoir sites, compel economy in the use of water.

These factors have aided in forcing the water-wheel manufacturer to furnish wheels for particular cases, and not from stock patterns. In order to furnish a wheel which will give the best results under the required conditions of service the designer must know certain facts. Mr. O. B. Coldwell, in a paper given recently to the American Institute of Electrical Engineers, and published in the last two issues of *The Canadian Engineer*, discusses the features entering into the particular design of water-wheel which will best reach the conditions for which it is intended, and points out the information which should be furnished by the purchaser to the water-wheel designer to enable him to plan the most efficient unit.

EDITORIAL COMMENT.

In this issue of *The Canadian Engineer* will be found the second part of the article describing the Red River Bridge for the National Transcontinental Railway. This is a bascule bridge of a new form, known as the "Heel Trunnion," and is a modification of the earlier form of bascule. This is the first description of the "Heel Trunnion" type that has as yet appeared in the technical journals, and will, therefore, be of considerable interest to our readers.

* * * *

Members of the engineering profession resident in Toronto will much regret City Engineer Rust's removal to Victoria, B.C. The integrity and uprightness which has marked his career throughout his municipal life has done much towards setting a proper standard for the engineering profession in Canada. At the same time we feel sure that the work of the Canadian Society of Civil Engineers and its influence in the West will receive an added impetus with the presence of the immediate past-president of the organization in Victoria. We wish Mr. Rust every success in his new sphere of action.

* * * *

We drew attention through our editorial columns recently to the application of the Sanitary District of Chicago for permission to divert an increased amount of water. The Canadian Government have very rightly taken a strong interest in the application, knowing the evil results that will accrue to Canada as the result of the granting of the application. To secure an intelligent understanding of the facts underlying and concerning the application, the Department of Marine and Fisheries has sent out a pamphlet giving the facts as known. An abstract of the pamphlet will be found in this issue.

GENERAL NOTES.

Precipitation was very generally in excess of the average in Canada during April, but in Vancouver Island and the Kamloops District of British Columbia, Saskatchewan and Nova Scotia, the usual amount was not recorded. The excess was pronounced in Alberta, where the fall was almost twice the normal in many localities.

At the close of the month the ground was bare of snow in most places, but in the bush region of Upper Ontario there was a depth of from four to twelve inches, and in the Gaspé Peninsula of Quebec about four inches.

The table shows for fifteen stations, included in the report of the Meteorological Office, Toronto, the total precipitation of these stations for April, 1912:

	Depth in inches.	Departure from the average of twenty years.
Calgary, Alta.	2.00	+1.41
Edmonton, Alta.	1.60	+0.76
Swift Current, Sask.	0.4	—0.35
Winnipeg, Man.	2.20	+0.66
Port Stanley, Ont.	3.50	+0.92
Toronto, Ont.	2.74	+6.34
Parry Sound, Ont.	2.34	+0.20
Ottawa, Ont.	3.14	+1.26
Kingston, Ont.	3.27	+1.28
Montreal, Que.	3.20	+0.88
Quebec, Que.	3.13	+1.10
Chatham, N.B.	3.20	+0.45
Halifax, N.S.	3.90	—0.62
Victoria, B.C.	1.30	—0.50
Kamloops, B.C.	1.30	—0.52

A FLOWING WELL.

The illustration given herewith shows No. 2 borehole which was sunk at Boggy Creek for the purpose of supplying water for Regina, Sask. Mr. R. O. Wynne-Roberts, the consulting engineer, after a study of the geological formation, decided that there should be water at this point, and on sinking a well, a gusher was located. This well is 75 ft. deep, 5 inches in diameter, and at 8½ ft. above ground it is now discharging 440,000 gallons a day. At 8 ft. below ground it is expected to yield about 700,000 gallons daily.

View of Well Showing Measuring Weir.

A few months ago Regina had only a supply of one million gallons per day; now there are 2,750,000 gallons ready for the city, and it is hoped to increase this to a still larger quantity from Boggy Creek. The next well to be sunk will be 7¾ inches in diameter and it is expected to yield a greater quantity than the 5 inch well. The photo is of interest because it is rare that such powerful artesian wells are to be found in the glacial formation. These wells should place Regina in an excellent position with regard to industries and financial operations. The view shows a temporary V-notch weir installed to measure the flow of the well.

ELECTRIC SMELTING OF IRON ORE IN SWEDEN.

The Stora Kopparbergs Bergslags Aktiebolag, at Falun, who are the owners of the Domnarfvets Ironworks, at which works the first large electric smelting furnace was erected, are now going to build a new electric furnace with a capacity of 12,000 h.p. The earlier furnace was constructed according to the designs of the Elektrometals Company. The new furnace, however, is to be constructed in accordance with the patents of Dr. A. Helfenstein, of Vienna, and a contract with the inventor has already been signed by the company. The Helfenstein furnace, which is fitted with vertically adjustable electrodes, has been adopted in several places in Germany and France in the carbide industry, and is also used for the production of ferro-alloys, the size and capacity of the furnaces varying from 6,000 to 12,000 h.p. This is stated to be the first time, however, that the furnace is to be used in connection with the iron industry. Among the advantages claimed for it is the fact that the capital expenditure per h.p. is small, and further, that it is simple in design, and the cost of operation is low. It can also be adapted to a varying supply of energy, which is of particular importance to works depending for their energy supply upon rivers and waterfalls. It is expected that the new furnace will be completed in the autumn, and possibly results will be available before the end of the year.

CENTENARY OF GAS LIGHTING.

The year 1912 marks the one hundredth anniversary of civic street illumination by means of gas and its importance, even in 1812, may be readily noticed from the fact that its application to street lighting followed its first public demonstration by just nine years. Mr. Samuel Gleg, the first business manager of the National Light and Heat Company (London), improved the art to a great extent by the introduction of the hydraulic main, the wet lime purifier and the wet gas meter. With these improvements gas rapidly spread over the civilized world as an illuminant, and Baltimore had the honor of being the first city on the American continent to use it for street lighting purposes. This was in 1821. Boston followed the next year, and by 1827 gas lighting had become common in New York City.

At first no attempt was made by the gas producing companies to secure any other product from the coal than the gas, but later on it was discovered that there were several valuable by-products. The products of gas distillation contain vapors of tar and naphtha together with steam impregnated with carbonate of ammonia and sulphide of ammonia. These vapors condense in the pipes and clog them up. Instead of being considered a nuisance it is now recognized that they have a value, and add considerably to the assets of the gas companies. Sulphide of ammonia amounts to one per cent. of the coal treated, although some thirty per cent. of this amount is lost. However, it is worth nearly twenty dollars a ton as a fertilizer, and gas companies in regions where fertilizer is most in demand find a ready market for all the sulphide they can produce.

When electricity began to come into use as an illuminant it was predicted on every hand that the gas companies would soon become bankrupt, and that gas would be driven out of the market. These prophecies have been falsified, for gas companies are more prosperous than ever. They are concentrating much of their energy in popularizing gas as a heating agent, for up to the present time electric heaters are more expensive, and have proved economical only in such small articles as irons. In a few years electricity may be much cheaper, and then it may drive its older rival from the field. At the present time, however, gas for heating purposes is firmly entrenched, and there are many who prefer it as an illuminant to electricity, for the reason that it is not so hard on the eyes as the fierce white glare of the electric light.

AN UNUSUAL COMBINATION OF REINFORCED CONCRETE AND CONCRETE BLOCKS.

The E. E. Woodward Building at Rockford, Ill., is notable in that the construction is a combination of reinforced concrete and concrete blocks. The entire frame, including columns, floors and stairways, is of reinforced concrete, while the walls and partitions are constructed of concrete blocks. No wood is used except for window frames. It is interesting to note that the blocks carry none of the load of the building and contents except their own weight. The building is 143 by 70 feet, five stories high with basement. The concrete used was proportioned 1:2-½:4. The Simpson Construction Co., of Chicago, were the contractors for the concrete work, while the building was designed by Francis M. Barton of the same city.

APPLICANTS FOR PUBLIC APPOINTMENTS.

To anyone who has had occasion to advertise for applicants to fill a position the following comments by a borough surveyor, in a recent issue of The Surveyor, will be of interest. It would be well for all applicants for positions to note carefully the remarks.

Only a very few of those of us who enter the municipal or local government service can hope to progress very far in our career without undergoing the ordeal of becoming a candidate in open competition for a higher position.

Again, only those who have entered the arena time after time without success can appreciate fully the dreadful sense of discouragement that comes over one on receiving quite a number of polite little circulars informing us that Mr. So-and-So of somewhere else has been successful.

Of course, in the public service, of whatever branch, the stress of competition, as in every other walk of life, grows keener day by day, and disappointments must be expected, if only from a study of the numbers one sees from time to time as having applied for this or that post.

Still, one often wonders just why the successful candidate should have been selected in preference to oneself. He does not come from as good an office as our own, he is younger, and does not appear to have nearly as good qualifications. "Luck," perhaps; well, very often it is just that and nothing more, or at any rate that intangible factor has entered very largely into the result. And yet if you were behind the scenes you would very often see clearly the why and wherefore. For while it is true, no doubt, that such things as "local influence" and "personal canvassing" are still potent powers in the land, I think it must be conceded that in nine cases out of ten nothing more or less than first of all a smart application ensuring a place on the selected list, followed by a favorable impression at the personal interview before the committee or council, has brought about the result. It surely behoves us, then, to put our very best effort into our application, recognizing that nothing but this has the slightest chance among so many aspirants, and always remembering that from this short document alone those who have the selection have to form an estimate not only of our qualifications, but, from internal evidence contained therein, our personal character.

It has been my duty to open, analyze and tabulate the applications received on several occasions, and quite recently to prepare a select list for a junior appointment in my own office. On completing my task I stood contemplating the heaped-up pile of human effort, wondering if I really had selected the the best six, or whether lying buried amidst the number of unsuccessful applications was some undiscovered gem of sterling worth.

This would, with every care on my part, have been quite possible, from the fact that so many of the applications bore evidence of want of training and method in preparation, and thus it may be that a candidate having really good points had quite failed to bring them to my notice. Let it be recognized, more especially by younger members of the service, that an application, to stand out from its fellows, must be prepared with that object, and be such as immediately to command attention.

Everything counts, right from the very envelope in which the application is sent to the testimonials it encloses. Handwriting, good paper, legibility, the marshalling of facts in clear chronological order of training and experience, general style and appearance—all lend their weight.

The first point, perhaps, that I can recommend is a very careful study of the advertisement, and having made this, consideration if you are in every way eligible. It is of no use blinking facts to oneself. Competition is so severe that unless you are competent from training and experience, or, for example, are not within the limits of age, it is useless to waste your own and other people's time by applying. Do not think from this that I wish to damp anybody's laudable desire to get on, and, of course, "luck" might come your way. Really, though, there are already so many people who cumber up the candidates' list and who by no possible chance can hope to succeed, that they cause themselves a deal of unnecessary trouble, expense and disappointment. Do not imagine I mean that, supposing a borough surveyor has a vacancy for a qualified "General Assistant," you are eligible because you have just completed your articles with an architect in private practice, or that for a public library requiring a librarian you are just the man because you are in a town clerk's office. You have not had the specialized training required, and fifty of the others who apply will have. Take any hint, also, contained in the public announcement of the vacancy, such as "preference given to candidates holding the certificate of the Surveyors' Institution." If you have not this diploma, its equivalent or something better, do not apply. Modern practice all tends towards specialization in greater or less degree. No, choose your department, and get every qualification you can that it requires, then sail ahead when opportunity offers and "Try, try again." Quite 30 per cent. of the applications I referred to a little while since were received from persons having no possible qualifications for the post, and this is no solitary example.

Having decided, then, to become a candidate, let us return once more to the advertisement. Follow its directions implicitly down to the smallest detail. If it asks for everything to be in the candidate's handwriting, do not, for instance, type or print your copies of the testimonials. If it asks for two testimonials, do not send in three, or any like foolishness.

It would be impossible here to do more than indicate generally the lines your application should follow, as the circumstance will vary in some degree with the class of appointment offered. You will, however, have already gathered the care and attention I advise you to pay to many things. As I have already said, you must remember that it will not only be from the subject-matter of your application that you will be judged, but an opinion will be formed of your general character from the internal evidence it contains. For instance, a man who makes careless mistakes there will be likely to make them elsewhere. If you attempt to deceive by palpable exaggeration there you are not likely to be reliable in your everyday dealings in your new post. If you do not produce a neat and businesslike document now, with so much depending upon it for your own advancement, are you likely to exert yourself to turn out good work in your employer's interest? Make the very best of your own goods —that's what you must do to succeed. But, on the other hand, do not state anything that will not bear investigation should it come to the test.

Among other small matters, address your application direct to the persons having the power of appointment, as, for example: "To the Mayor, Aldermen and Councillors of the Kirkhampton Town Council," or "To the Chairman and Members of the Wallsend Urban District Council," "Gentlemen." Then go right to the point. Do not say, as nine out of every ten candidates will: "Having noticed your advertisement in this week's Local Government Gazette for a general assistant in your surveyor's office, I beg, etc." Never mind how you got to know there was a vacancy. Say: "I beg to offer myself as a candidate for the position now vacant of general assistant to your borough surveyor."

Then give your true age on your last birthday. Do not quibble in order to make yourself appear a little older by saying "I am in my twenty-sixth year." If it is the end of February now, of course you can, if you wish, say "I was twenty-six years of age on March 14th last."

Then particularize your present appointment and qualifications, and go on to show (guided, of course, by the nature of the appointment) how your education, your having served your articles of apprenticeship, your subsequent appointments, the examinations you have passed, and your experience generally fit you in every way for the position offered; and, if a junior, impress them with the fact that you will prove a real assistant to your new chief if appointed.

Of course I can do no more than indicate that there are ways, by using your brains a little, of helping you considerably so to frame your application as to meet exactly the requirements of the situation. For example, let us suppose that a bald advertisement appears stating that the council of some seaside resort requires a new borough surveyor. You have never been there, and do not know the town a bit. Well, make it your job to find out everything there is to know of the class of place it is, and what special matters (like waterworks, public baths, or other projects, just a little outside the usual run, perhaps) will be under your control. Or, again, make a special point of enquiring what new large works, if any, are contemplated in the near future, such as an extension of the sewage system, or a new sea-defence wall and parade. Having gleamed what you require, it is easy to emphasize in your application that part of your experience bearing on the points in question. Obviously, for instance, on the other hand, it is no use to indite long paragraphs setting forth your special knowledge of sewage farms if the sewage is discharged direct into the sea. Need I say more? The advertisement will often give you general information, but frequently it is easy to gather a little particular knowledge of the greatest service. Before leaving this part of our subject, just a word more to the juniors—and that is, "Do not exaggerate." I have before me an application for a junior appointment from a boy in a borough engineer's office—a veritable prodigy if all he states is true, for he claims to have a thorough knowledge of surveying and levelling in all its branches, is an experienced draughtsman, with special knowledge of architectural work, and sewage and drainage, road making, private street works, waterworks and tramways, and yet makes at least two mistakes in spelling. Believe me, the man who is going to look through through your application will not expect all these things of you before you are twenty-one. He is more likely to be content with a genuine statement that during your articles your chief has been carrying out works of the comprehensive nature set forth above; that you have got some satisfactory knowledge of office routine, can make an accurate survey, produce a neat drawing, have passed a preliminary examination, or can produce a certificate or two from the Science and Art Department of the Board of Education in building construction or the like. I declare it to be an absolute fact that out of six selected candidates for a junior appointment who appeared before a committee here, and all of whom had stated in their application that they were competent surveyors, only one could read an angle set up on a theodolite standing in the council chamber, and four of the six were not able to make any attempt at all. Be warned, therefore, and do not hope to deceive by claiming to be able to run while still "in arms," for you would only be miserably unhappy if by any chance you managed to secure the position and were found wanting.

And now as to testimonials. I am afraid at this date, while they are still the fashion, their value has been considerably discounted owing to experience common to us all. Let them at any rate have some bearing and be a little varied. By that I mean get them from people competent to form a judgment. To produce one from your schoolmaster when you are twenty-five has only a limited value. He cannot judge but generally of your professional ability. Suppose, for instance, three are required; get two that speak of your professional qualifications, and let one go to show something of your personal character.

Your application is now ready for dispatch, printed it may be, and neatly bound up in narrow green ribbon for an important post, typed or neatly written for others, but always with an outside title page setting forth tersely its contents. Send it off then in good time; do not wait until the very last day or post. There are such things as accidents; and do not forget to put the endorsement on the outside of the envelope.

On the much-debated question of convassing I shall say but little. In many instances this is now strictly forbidden, but in others "personal" canvassing only is tabooed, and it is still permissible to send a copy of your application and testimonials to the members of the local authority or committee. The names you can easily obtain, as a rule, on application, or from the local newspaper people. Do not forget that you must spare no legitimate effort to make your name stand out from the ruck in some way or other—even if it is only by using blue foolscap instead of white. As to any personal influence you may be able to bring to bear, I can only leave that to your own good sense and taste; but always remember that frequently more harm than good is done by the people who pester on behalf of candidates of whom they have no real personal knowledge whatever.

Now only remains the fateful interview. Our application has done the work required of it, and we have been requested to present ourselves as one of a selected number for inspection. Here, of course, a man's personality counts for a very great deal, and it is everything to create a good impression. I am afraid it is of little use to tell the nervous man, who positively dreads it, not to be afraid, but one can warn the very cocksure of going to the other extreme.

All things count, dress and general appearance, of course. Do not overdress, but, at any rate, go looking, as it were, worth your money. Perhaps, however, the one great tip is contained in the words "Speak up." There are sometimes quite a number on the committee or council, and there are certain to be some who cannot hear well; but anyhow it gives a general impression of confidence.

You must be on the alert for opportunities to bring out your strong points. Do not worry by anticipating that they are going to ask you too much or questions you may not be able to answer. They will not; for, as a matter of fact, unless the interview has been arranged beforehand by the chairman or head permanent official, you will be surprised at the somewhat inane things that will be asked of you, or find that you are being merely required to confirm a few points in your application. You will not often get a chance to say much to the point unless you are quick to make the opportunity for yourself as you go along. In conclusion, I wonder if I shall be understood if I tell you never to say "No" to anything.

Reading over the foregoing I very much doubt if I am competent to give you all the advice I should like to give. Certainly I myself have made very nearly all the errors I am asking you to avoid, but if I have succeeded in helping any of those who are coming after me to put up a little better show on the next occasion they enter the list my efforts will not have been entirely in vain.

CIVIC STREET ILLUMINATION.

The many and important changes brought about in the matter of street lighting are becoming noticeable throughout the streets and thoroughfares of nearly every Canadian municipality. The changes have not been so noticeable in the method of supply but in the means of light distribution and the method of fixture treatment along the streets.

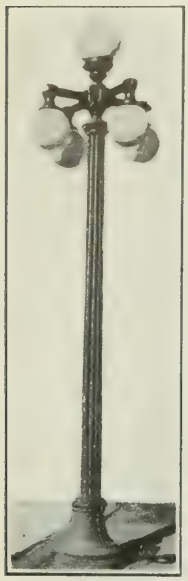

Fig. 1.

In the lower portion of the province of Ontario the policy of the Hydro-Electric Commission has been a potent factor in the furthering of new systems of street illuminations, but that this policy is not alone responsible for these changes is exemplified by the large number of municipalities who have discarded the arc flame system for the incandescent standards and still rely on steam driven dynamos for their current.

In many cases the design of the supporting columns has been carried out to an advanced state of perfection with the result that the appearance of the highway has been greatly improved and enhanced.

There are many advantages attending the use of these incandescent standards over the use of the arc lamp, and among these may be mentioned the even distribution of light, the reduced cost of maintenance, and the civic beautification.

Fig. 2.

The city of Toronto, Ont., lays claim to being among the first cities in Canada to entertain and carry out a progressive system of municipal street lighting.

In the execution of this work two types of lamp standard were employed; one consisting of an ornamental cast iron, circular base carrying five globes (four inverted and one upright); the other a reinforced concrete pole carrying one lamp in a cylindrical iron and glass support over the sidewalk. These latter standards are used on the residential streets and sections; the use of the former being confined to the heart of the business section.

As a general rule, the designers of these ornamental standards have allowed facilities for five globes; four being supported on cross arms and the fifth projecting from the end of the supporting column. Figure 1 gives an idea of the appearance of the large standards in the city of Toronto.

Aside from the necessity of careful planning and engineering there appears to be one important factor which must be considered before the system is a success, and that is, the nature and manufacture of the glass globes that surround the incandescent lamps. The Macbeth-Evans Glass Company, of Pittsburg, Pa., have made a study of this phase of the problem and have advanced the art to such an extent that they have received orders from many large and important municipal councils in this country. All the globes appearing in the illustrations accompanying this article were supplied by the above mentioned firm.

Figure 2 represents the appearance of a residential street in Toronto that was among the first to receive treatment from the Hydro-Electric Department. This street branches from the main thoroughfare and extends for a distance of about two long city blocks. As may be noticed from the posts in the foreground, two iron rings painted dead black support the ground glass globe and a metal crown on the top completes the make-up of the fixture.

The treatment of the down town sections is illustrated in Figure 3, which shows up under exceptional circumstances owing to the almost entire absence of other poles or posts. It will be noticed that the iron standards receive their operating current from wires buried underground, while the concrete standards are fed from top wires carried by the pole itself. In a few cases the iron fixtures attached to the con-

crete standards have been placed on tall wooden poles in certain sections of the city, but these poles are used to carry feed mains other than those used for supplying the lighting standards only.

The following table gives the more important specifications and figures of the lighting system of Toronto and Buffalo, N.Y. It affords a practical basis for cost estimation of similar equipment.

Fig. 3.

	Toronto, Ont.	Buffalo, N.Y.
No. of posts in installation	450	86
Typical street width	42′ 0″	60′ 0″
Post spacing	80′ to 100′	105′ to 125′ staggered
Height of post	10′ 8″ 13′ 0″	10′ 6″ 12′ 6″
Lamp arrangement	1 upright 4 pendent	1 upright 4 pendent
Size of lamps	5 100-watt	5 60-watt
Size of globes	(12″ x 6″) (14″ x 7″)	(12″ x 6″) (16″ x 8″)
Methods of wiring	5 Multiple lamps in series on 550V power circuit	Multiple
Kind of current	Alternating	Part direct and part alternating
Location of wiring	Underground	Underground
Time of burning	All lamps burn all night	All lamps burn all night

Some manufacturers of dairy machinery are now using monel metal for those parts subject to corrosion, experiments having shown the chemical resistance of this metal, and also its particular suitability for making pails, pans, ice cream freezers and the like.

MAINTENANCE OF THE DIESEL ENGINE.

The following notes published in a recent issue of The Electrical Review, of London, will be of interest to Canadian engineers, for a number of Diesel engines are now being installed in this country.

After two years' experience of this class of engine, the writer has no hesitation in saying that such engines are quite reliable for central-station work; any trouble experienced at first was entirely due to lack of experience on the part of those in charge.

Unless the valves, &c., are kept in practically perfect condition trouble will be experienced in starting, as the engine depends entirely on the compression for firing the charge; some engineers will consider this an advantage, but it is a serious matter for a supply station should an engine fail to start when the load is rushing on.

Where one engine only is installed, the question of the starting air is of great importance, and a small compressor, driven independently of the engine, is almost a necessity. Where there are more engines than one, it is not likely that all will be out of order at the same time, and the supply of air is practically assured.

The engine most likely to fail to start is the single-cylinder type, the multi-cylinder engine being almost certain to run on one cylinder unless allowed to get into a very bad state. Therefore, the question of the supply of air is not so serious in this case.

In a residential district the noise of the exhaust may be objected to; while it is by no means excessive, the persistent rap is objectionable, especially at night.

In a case with which the author is familiar this was overcome by taking the exhaust into a pit, 10 ft. by 6 ft. by 6 ft deep, which was available, the outlet being through the silencer supplied with the engine, and it is now almost im-

possible to tell when the engine is running. In addition to the reduction of noise the back pressure on the engine was considerably reduced.

The engine ran for some time without trouble, the first failure to start being due to the exhaust valve buckling slightly, making is impossible to get the compression high enough for ignition.

The exhaust valve casing worked loose several times, and when it was tightened down hard the casing itself buckled; each of these events meant failure to start and loss of air. In one case the air pressure was as low as 200 lb. in one starting receiver and 450 lb. in the reserve, while there was 650 lb. in the blast receiver; even with this low pressure it was possible to start up on pure paraffin.

This trouble was overcome by having the shoulder of the valve casing turned down a little from the top of the seating.

The exhaust valve soon gets pitted and scored, and it requires grinding in about every three months on an engine running six or seven hours per day. It is only a matter of a quarter of an hour to change this valve, a spare valve and casing being supplied with the engine and a split lever allowing this to be removed without disturbing the other valve gear.

The air valve has given very little trouble, although it requires occasional grinding in, and once was badly "gummed up" with imperfectly consumed fuel; the cause of this is mentioned later.

As regards the fuel valve, the makers appear to consider that it requires more attention than other parts, but during two years' working this valve has given no trouble. It has been regularly cleaned and rubbed in once or twice with knife powder when overhauling the engine.

The starting valve stuck open several times when starting up and completely emptied one of the air receivers. This was found to be due to an accumulation of moisture in the receiver being carried into this valve and causing the spindle to rust and stick in its casing. The trouble was overcome by giving careful attention to the draining of the interccoler while the engine is running, and regularly draining the air receivers each day.

The lubrication of the compressor gave some trouble at first, because of the high-pressure valves occasionally sticking and causing a shut-down owing to the falling of the blast pressure, and the air pipe from compressor to intercooler becoming blocked by carbonized oil; the makers recommended that the oil supply to the high-pressure piston should be discontinued altogether, except for a few minutes after starting up, and this was found quite sufficient for lubrication and completely overcame the trouble.

The lubrication of the engine has given no trouble except for the piston, which requires careful attention. In most vertical type engines the oil is pumped into an annular space round the cylinder and reaches the piston through some six very small holes in the cylinder liner; these appear to be very liable to get blocked up and as it is necessary to dismantle the whole of the valve gear and draw the piston, to enable an inspection to be made, they are liable to be overlooked.

The piston has run dry twice in the two years, although drawn every six months for inspection, and in each case two of the holes were found blocked up. Fortunately the driver noticed the trouble before any damage was done to the piston.

The fuel pump valves require careful attention, and particularly the suction valve as any leakage past this will prevent the engine developing full power. Failure to start has resulted more than once through the suction valve casing working loose on its seat; this was not an easy fault to locate the first time is occurred.

The cooling water must be carefully watched, and it is suggested that the circulating pump, driven from the engine, is not sufficient, but that a supply should be available to continue a flush of water through the engine for about fifteen minutes after shutting down. The reason advanced is that the heat of the piston and cylinder walls is sufficient to bake any sediment left by the water into a hard scale. This assumes that the water runs out of the engine when the pump is stopped.

A cracked cylinder cover was another unexpected trouble, and the writer believes that this has occurred on more than one engine of this type. The only reason which has been suggested for this is that the engine must have been seriously overloaded or that scale had formed in the water passages, and the latter point will be definitely settled by opening up the damaged cover.

The crack was so slight that some difficulty was found in locating the trouble. The engine failed to start and the usual examination was made, all valves were ground in and rocker lever clearances set. The engines started up sluggishly on pure paraffin and ran as usual, but refused to start on ordinary fuel oil.

Indicator diagrams were taken (the engine again being started on paraffin) and the compression was found to be very low. A careful examination revealed a tiny crack on the seating for the exhaust valve casing, extending through to the seating of the fuel valve casing. On one side of the crack the seating was slightly raised, preventing the exhaust valve casing from bedding properly.

During the few hours the engine was running on this low compression, the whole of the valves and cylinder head were gummed up with imperfectly burned oil.

It will generally be found that the engine will be somewhat sluggish in starting when anything is getting out of order, it is therefore a simple matter to get things right before a failure to start occurs. Naturally one must have practical experience of the peculiarities of Diesel engines to ensure their absolute reliability.

Th freedom from accumulation of carbonized material of valves, piston, and cylider, is remarkable, and very little trouble is experienced in cleaning up when overhauling. The maintainance cost is also low, and is chiefly confined to the pipes and valves dealing with the compressed air. The high pressures used cut the valves at a rather serious rate.

There has been no falling off in efficiency, and the ease with which the exact cost per unit can be ascertained each day is very different to the practically guesswork method of the smaller steam power stations.

More lubricating oil is required than with a steam engine only, but if the auxiliaries of the steam plant are included, there is little difference; it will be found better not to depend too much on oil filters, as they do not appear to separate out the carbon properly.

The writer cannot speak from experience of long nonstop runs, the longest coming under his personal observation being of 120-hours duration. There is no reason to doubt that very long runs are possible, the only limit being the length of time the exhaust valve would remain good enough to retain the high compression necessary.

No mention has been made of fuel costs, as these are so well known, and it is sufficient to say that the maker's guaranteed figures are still maintained under working conditions.

WATERPROOFING ENGINEERING STRUCTURES.*

By W. H. Finley.†

My attention was first directed to the necessity for some method of waterproofing engineering structures by the number of limstone masonry arches that were slowly but surely deteriorating, due to the infiltration of water. Investigation disclosed that very little had been attempted along this line, and no definite information could be obtained regarding methods or materials. The waterproofing of a masonry arch presents no very difficult features, and my earlier attempts in this direction met with a fair degree of success. However, since the extensive introduction of the elimination of grade crossings in cities by the elevation of railways, the problem of waterproofing has been greatly complicated by the necessity for making the subway bridges water tight.

This has caused very rapid development in both methods and materials for waterproofing, until now you can get all sorts of information as to how it should be done and what materials to employ, and yet the problem is far from being satisfactorily solved. Engineers have received some very rude shocks in this line of work, causing them, at times, to doubt whether it was possible to do a satisfactory job of waterproofing. The rapid expansion in this field has

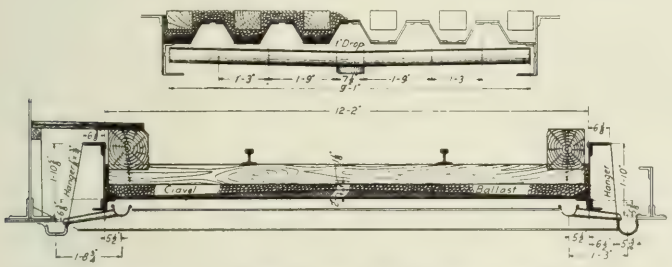

Fig 1—Section of Bridge Over Main Street Rockford, Ill.

brought into existence the waterproofing "expert," who takes his place along with the paint expert, who has for years periodically offered us a paint that would at last prevent the corrosion of metal structures; and yet the corrosion of metal structures still goes on.

While listening to the rival claims of advocates of different methods of waterproofing, the engineer must not lose sight of the fact that waterproofing, at best, is but an expedient, and will not take the place of proper designing, or correct poor construction. Water is a universal dissolvent, and if not gotten rid of in time will seep through the ordinary materials of construction. The first requisite in the designing of any structure that must be water tight is to provide means of getting rid of the water as directly and quickly as possible. In the numerous track elevation bridges around Chicago, whatever the type of construction, the usual practice has been to slope the floor from the centre to each end, carrying the water away back of the abutments, and right here is where much trouble has developed. Although one may place broken stone filling and tile drains back of the abutments, when the surface ice and snow melts in the springtime and the filling back of the abutments is still in a frozen condition, the water does not escape freely, but piles up and eventually seeps through at the end of the bridge and flows over the face of the abutment. In bridges having supports on curb lines and in the middle of the street, whether of flat slab construction or metal troughs filled with concrete, cracks are likely to appear where joints are not provided for over these supports, and where joints are provided for, trouble is likely to be experienced in preventing the seepage of water.

I will now take up, in a general way, the different methods and materials in use, and will first mention what is called the integral method. This method consists in adding a paste, powder, or lixivating water to the concrete, mixing it with the cement, the mass of concrete as a whole or with the water. While there is no doubt that any of these methods will make concrete impervious to water, as indeed can be done with ordinary concrete by careful proportioning and selection of aggregates, with subsequent care in placing, yet we know that monolithic concrete is apt to develop cracks from a variety of causes, and when that occurs you are likely to have seepage of water through the mass. For that reason I have always preferred for waterproofing engineering structures what has come to be called the membrane method.

When I first took up the question of a suitable material for waterproofing engineering structures, I investigated the respective merits of asphalt and coal tar pitch. The only instance of the use of the latter with which I was familiar had not proved very satisfactory, and I decided to use asphalt. At that time there were very few, if any, artificial asphalts on the market, and I necessarily used a natural asphalt. The structures then waterproofed are still in good condition. Since that time there has been an extensive development of artificial asphalts from petroleum oils. In nearly all cases it is claimed that the artificial asphalts offered for waterproofing purposes have a Gilsonite base. Gilsonite is described by G. H. Eldridge in his article on "The Asphalt and Bituminous Rock Deposit of the United States," as "a black, tarry-looking substance of most brilliant lustre, normally of absolutely homogeneous texture and exceedingly brittle." It is found in the Minta basin, Utah, and takes its trade name from S. H. Gilson, an early prospector. It occurs in vertical veins in enclosing sandstone, and the veins vary from a knife edge to 30 in. in thickness. It is generally conceded that the origin of Gilsonite and other hydrocarbons may be traced to petroleum. Inasmuch as the sandstone in which Gilsonite occurs contains no trace of petroleum, it is evident that it was forced up from a great depth by an enormous pressure. Gilsonite is a very pure form of hydrocarbon, and is used in a variety of ways in the arts and trades. It is used in varnishes and baking Japans, insulating materials in electrical work, and for making mineral rubber, as well as in the artificial asphalts. Taking the amount of waterproofing asphalts that are turned out every year I was interested in learning the total production of Gilsonite. I found from a reliable source that the total production last year was in the neighborhood of 30,000 tons, and the previous year somewhat less. I am afraid that the Gilsonite base of our artificial waterproofing asphalt is a very thin one. Petroleum oil is not a uniform product, varying very much at different places, and for that reason I have always been fearful that in asphalts made from petroleum oil we would not get a uniform product. However, I have had tested a number of artificial asphalts and found them to fill the following specifications very easily.

Material.—1. (a) Asphalt shall be used which is of the best grade, free from coal tar or any of its products, and which will not volatilize more than ½ of 1 per cent. under a temperature of 325 deg. F. for seven hours. (b) It must not be affected by a 20 per cent. solution of ammonia, a 25 per cent solution of sulphuric acid, and a 35 per cent. solu-

*Abstract of a paper before the Western Society of Engineers, March 18, 1912.

†Assistant Chief Engineer, Chicago & North-Western.

tion of muriatic acid, nor by a saturated solution of sodium chloride. It should show no hydrolytic decomposition when subject, for a period of ten hours, to hourly immersions in water with alternate rapid drying by warm air currents.

Range of Temperature.—2. (a) For metallic structures, exposed to the direct rays of the sun, the asphalt must not flow under 212 deg. F., nor become brittle at 0 deg. F. when spread thin on glass. (b) For structures underground, such as masonry arches, abutments, retaining walls, foundation walls of buildings, subways, etc., a flow point of 185 deg. F., and a brittle point of 0 deg F. will be required. (c) A mastic made from either grade of asphalt by mixing it with sand in the proportion of one of asphalt to four of sand, must not perceptibly indent, when at a temperature of 130 deg. F. under a load of 20 lbs. per sq. in. It must also remain pliable at a temperature of 0 deg. F.

In asphalting a metal surface it is imperative that the metal be cleaned of all rust, loose scale and dirt, and if previously coated with oil this must be burned off with benzine or by other suitable means. The metal surface must be warm to enable the asphalt to adhere to it, and the warming is best accomplished by covering it with heated sand, which should be swept back as the hot asphalt is applied. When waterproofing concrete structures it is very necessary that the surface be thoroughly brushed with wire brushes to remove all loose particles and get rid, as far as possible, of what the French call "laitance." It should then be coated with a liquid asphalt primer, and I believe that better results will be obtained if, just ahead of the application of this primer coat, the surface is swabbed with gasolene.

I am not an advocate of felts or burlaps for ordinary waterproofing. I believe that any ordinary concrete surface, whether in a slab bridge or an arch, needs nothing but an application of a primer coat of asphalt and then a coat of liquid asphalt, after which a hot sand mastic, composed of one part of asphalt to four of sand, can be applied with hot smoothing irons. On top of this it has been my practice to put on a swabbing coat of hot asphalt and then to cover the whole surface with washed gravel, particularly where rock ballast was to be used. Over joints and ends of bridges it may be necessary to use burlaps for the added strength they give the asphalt in taking care of any slight movement. However, in cases of expansion joints, where any defined amount of movement is to take place, I believe that special means, such as copper flash joints, should be used. Burlap is a vegetable fibre and if used should be thoroughly saturated in a bath of hot asphalt of such temperature that it will not char or destroy the fibre. To apply asphalt to raw burlap in the field I think is wrong. If the asphalt is hot enough to penetrate the fibre it is likely to be so hot that it will char or destroy it, and if the asphalt is not hot enough one gets only a surface coat.

I would like to repeat what I have previously said about the necessity for so designing your structure that the water can be disposed of as directly as possible. If more care were taken in designing, elaborate or expensive forms of waterproofing would be unnecessary.

Asphalt has no affinity for water, and all surfaces that are to be coated with asphalt should be as dry and clean as possible.

The methods I have used in preparing the asphalts are as follows:

The asphalt should be heated in a suitable kettle to a temperature not exceeding 450 deg. F. If this is exceeded it may result in "pitching" the asphalt. Before the "pitching" point is reached the vapor from the kettle is of a bluish tinge which changes to a yellowish tinge after the danger point is passed. If this occurs the material should be tempered by the addition of fresh asphalt. The asphalt has been cooked sufficiently when a piece of wood can be put in and withdrawn without the asphalt clinging to it. Care should always be taken not to prolong the heat to such an extent as to pitch the asphalt. Should it become necessary to hold the kettle for any length of time, bank or draw the fire, and introduce into the kettle a quantity of fresh asphalt to reduce the temperature.

There is a wide difference between the requiremnts for damp proofing waterproofing to take care of ordinary rainy weather and waterproofing where it is necessary to take care of the hydrostatic pressure of a head of water. In the latter case felt, and burlap mat properly reinforced with concrete, will be necessary.

Fig. 2—Shallow Ballasted Floor Bridge in Highland Park, Ill.

One of the early applications of waterproofing was made on a stone arch bridge over Turtle Creek near Shopiere, Wis., on the Chicago North Western. This bridge consists of five 50-ft. arches, and was built in 1869 of Joliet and local limestones. The seepage of water through the ring and parapet walls reached such a stage that it seriously threatened the life of the structure. In 1887 this arch was uncovered and the top thoroughly waterproofed with California asphalt. Three years ago I removed the filling and took up some of this natural asphalt, finding it in first-class condition. The waterproofing of this arch at this time prevented any further leakage, and unquestionably prolonged the life of the structure. I have waterproofed a number of old stone arches that were showing signs of disintegration due to the lack of drainage. In 1896 a couple of 30 ft. arches over streets in the town of Janesville, Wis., were in such condition that it was a question whether they should be rebuilt or not. These arches had been built in 1864 of limestone with lime mortar. Inasmuch as the double tracking of this portion of the road some time in the near future was completed, it was desirable to carry these arches as long as possible. They were uncovered and thoroughly waterproofed with asphalt. This prevented any further deterioration from the seepage of water, and in 1906, over ten years after the waterproofing was applied, these arches were replaced by double track concrete arches. The asphalt was found to be in excellent condition and a part of it was used in waterproofing the new arches.

Fig. 1 is a view of a three-track bridge over Main Street, Rockford, Ill. This bridge was built in 1893, and waterproofed with California natural asphalt. During the 18 years it has been in place there has been no complaint regarding the dripping of water or leakage from the bridge, although it is over the principal street in Rockford. I attribute this largely to the fact that the water is drained from each floor trough into drainage troughs and carried by pipes through the abutment and outside of the dump. This is one instance of getting rid of water as directly and as quickly as possible. It avoids the trouble that is usually experienced at the end of the bridge where the drainage is carried from the centre to each end. The only trouble experienced with these troughs is from birds building their nests in the same during extended dry spells. These troughs have been renewed once since they were first installed. In later work troughs for a similar purpose were made of a much heavier material. The locomotive stands on this bridge while discharging and taking on passengers at the Rockford station, and I have seen locomotives with their waste water cocks open pouring large quantities of water on this floor, which was carried off directly and without any trouble.

Figure 2 shows a very shallow ballasted floor bridge over Vine Avenue, Highland Park, Ill. It was necessary to provide a water tight floor at this point, and this type of floor was adopted. It has troughs, and instead of carrying any of the water back of the abutments it is actually carried down in front of the abutment through troughs and down spouts. These troughs can be so arranged that it would be impossible for any trouble to occur from birds building their nests and stopping the troughs. This bridge was built in 1902.

Figure 3 is a view of a subway on what is called the Kinzie street track elevation, Chicago. You will note in this case the water is carried from the centre of the subway to each end. A somewhat different method than I usually employ was used in waterproofing this bridge. The asphalt is imported mastic fluxed with Trinidad and Bermuda, and the asphalt mastic is covered by a layer of reinforced concrete. This work was done in 1905, and has proved very satisfactory, with the exception that there is some seepage of water at the ends of the bridge over the abutments. The method employed in sealing for the end, as shown in this view, did not seem to be completely satisfactory.

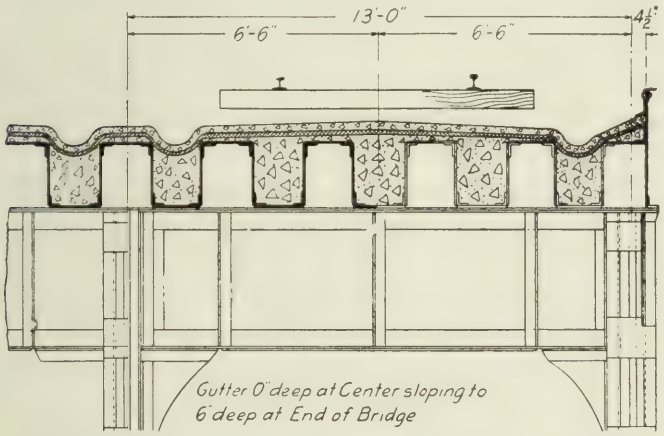

Fig. 3—Section of Subway Over Kinzie Street, Chicago.

Figure 4 shows a proposed treatment of the ends of city subways to prevent the possibility of water getting through and flowing down the face of the abutment. This is an attempt to seal it off completely by the use of a burlap mat instead of the usual bent plate method that we have previously used.

The bridge over Wauwautosa Avenue in the town of West Allis, Wis., is similar in construction to the Vine Avenue structure. Last fall it was necessary to remove this bridge to make way for improvements at that point, and I was very much gratified to see how thoroughly the iron had been protected by the asphalt mastic. A bridge of this type with such a shallow floor is subject to more or less vibration and deflection that would, under ordinary conditions,

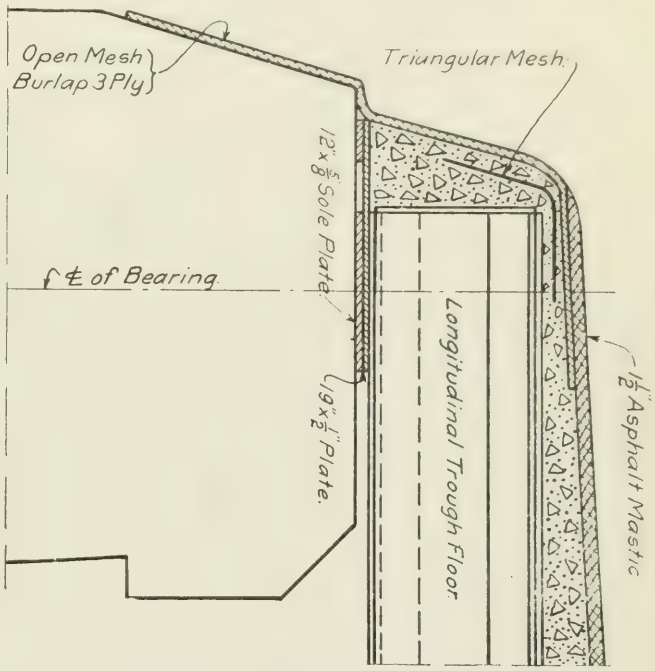

Fig. 4—Proposed Treatment of the Ends of Subways.

make it very difficult to waterproof. However, in this case, when the bridge was taken apart and the asphalt removed there was no indication of any rust or seepage of water through or under the asphalt.

CEMENT SEWER PIPE.*

By Gustave Kaufman, C.E.

The matter brought out in this paper is based upon the experience gained from the use of concrete sewer pipe in Brooklyn. As is generally known, about 400 miles of such pipe, below 24" in diameter, have been laid and is in use there. It can be truly said that this pipe has given eminent satisfaction to the authorities and has been maintained at a lower cost, per mile, than vitrified clay pipe of the highest grade.

Before starting upon the real subject of this paper a description of this pipe and method of its manufacture, is here given.

Pipe are made in 6-inch, 9-inch, 12-inch, 15-inch, 18-inch and 24-inch equivalent capacity. The 6-inch and 9-inch are plain round pipe; they are all three feet in length, with hub joint, with the exception of the 6-inch which is two and one-quarter feet. The 12-inch pipe is round with flat base, and the 15-inch, 18-inch and 24-inch pipe are egg-shaped, with flat base. The thickness of the walls are as follows:—

*Presented at the Eighth Annual Convention of the National Association of Cement Users, Philadelphia, Pa.

6-inch	3/4"
9-inch	7/8"
12-inch	1 1/16"
15-inch	1 3/8"
18-inch	1 5/8"
24-inch	2"

The collars are as follows:—

6"	collars—1 5/16"	in	depth	with joint of	1/8"
9"	" 1 5/16"	"	"	"	1/8"
12"	" 1 5/8"	"	"	"	3/16"
15"	" 1 5/8"	"	"	"	1/8"
18"	" 1 5/8"	"	"	"	3/16"
24"	" 1 3/4"	"	"	"	1/4"

These cement pipe up to 1890 were made by hand, when pipe made by machines were introduced by the Wilson & Baillis Manufacturing Company. With the hand-made pipe it was always difficult to thoroughly mix the ingredients of the concrete unless the workmen were closely watched and frequently resulted in a pipe far from homogeneous and of equal density throughout. In the manufacture of the machine-made pipe the cement, sand and trap rock are measured and thoroughly mixed in the machine mixer, evenly fed to the molds, and rammed by machinery with iron rammers regulated to produce continuous and uniform blows of any impact desired. The result is a product perfectly homogeneous and of equal and great density throughout.

The machine used for manufacturing the pipe consists of a mechanical tamper and a revolving table upon which the molds are placed. The tampers have a vertical reciprocating motion and at the same time move outward and inward rapidly so as to conform to the line of the travel of the mold which owing to its oval form, presents, at each revolution, varying diameters to the successive tamping bars. There are eight tampers made of the best tool steel, running two hundred tamps a minute each. Only one rammer is down at a time. The head, which consists of the actuating machinery for the tampers, is counter-balanced upwards as the mold is being filled with concrete. The head is raised by the density of the concrete and in this way an even and regular product is obtained which is impossible to achieve by hand. The force of the blow of each rammer is about one inch square.

The proportions, which have been used in later years, are one and one-half parts of the best grade of Portland cement, one part of sand and three parts of trap rock screenings, containing twenty per cent. of stone dust. The percentage of water used to the whole bulk varies from ten per cent. to fifteen per cent., according to the condition of the ballast. The mix when dumped on the floor is apparently dry, but will ball in the hand with some pressure. An extra mix is used in forming the collar for the reason that as the rammers do not exert a direct blow on the material in the offset compression of the material must be depended upon.

The mixed concrete is delivered to the machines in barrows and it is fed into the hoppers by two men, one on either side. As soon as the flask is full, and the core automatically lifted clear, the flask is taken up by a pipe truck and wheeled into the stripping rooms where it is allowed to stand usually thirty minutes when it is stripped. After the pipe have set over night a spray of water is turned on and the pipe kept damp until at the expiration of six days they are removed from under cover and placed in the yard. The pipe, at the expiration of thirty days, are set sufficiently to be handled in the work.

Spurs for house connections are connected on the pipe. A hole is cut at the proper point on the side of the pipe and a mold is placed in the interior. Cement mortar is then spread over the mold and the connection piece is bedded in place and a heavy band of mortar is wiped around the joint on the outside. After the mortar is removed the inside joint is finished with a trowel. This method has been found to be entirely satisfactory.

The main advantages of cement or concrete pipe over vitrified clay pipe, are:—

First—They can be constructed so as to give them an oval or egg shape.

Second—They can be made with practically no variation in size.

Third—They can be constructed with a flat broad and level base.

Fourth—The joints can be made so that the pipe are self-centring, and so that the joints will fit so closely that a continuous smooth bore can be obtained.

Fifth—They can be made in many localities where the cost of vitrified pipe is prohibitive.

Oval or egg-shaped pipe are very desirable where the flow of sewerage is variable and where the gradient is very slight. The small invert will permit the flow of small quantities of sewerage with minimum friction on account of the wetted perimeter being less than in the circular pipe.

Pipe of such shape are thoroughly self-securing whenever there is an increase in the flow of the sewerage and besides will effect a decided saving in flushing water. Pipe of this shape cannot be made of vitrified clay due to the wrapping in burning.

In the transactions of the American Society of Civil Engineers, June, 1911, Mr. Geo. T. Hammond, of Brooklyn, while discussing the paper on Monterry Water Works and Sewerage, strongly advocated the use of the egg-shaped pipe, even as small as 8" in diameter. In the Monterry system, eight-inch vitrified pipe was used, but its capacity was much greater than necessary at present. Mr. Hammond says:—

"The writer's experience with concrete pipe derived mainly from a long service in sewer design and construction in Brooklyn, N.Y., leads him to believe that at Monterry the whole system might, with advantage, have been built with concrete pipe, using an egg-shaped pipe with an area slightly larger than an 8-in. circle designed for a discharge equal to an 8-in. pipe for all the smaller sewers. The invert of such an egg-shaped pipe would fulfill the present requirements in carrying a very small flow with good flotation depth, better than would a 6-in. circular pipe, and the reserved capacity of the 8-in. pipe would be secured without interfering with good present service. Egg-shaped pipes, similar to those used in Brooklyn, the writer believes, would have given far better satisfaction throughout the Monterry sewerage system than circular fire-clay pipe, and would have cost no more, but probably less. The egg-shaped pipe referred to is made with a flat base and a self-centering joint, thus insuring perfect alignment, and a smoother interior surface than can be obtained with fire-clay pipes."

Cement pipe, in curing, retain accurately the shape given them by the molds. Vitrified clay pipe pipe, especially in sizes from 15" and up, are considerably warped, due to the burning.

In Brooklyn and many parts of Europe concrete sewer pipes are molded with a flat level base. Such a base permits the pipe to rest on a flat foundation, either earth or plank, and thus permits of better back filling. Improper back filling is the cause of much breakage in circular pipe, not supplied with a flat base.

The joints of cement pipe should be so designed that the hub and socket will accurately centre themselves. This can be done in cement pipe by making the socket with slightly flaring ends thus causing the hub, when driven home, to cone to its proper position. The vitrified pipe, on account of the warping in burning, must have wide sockets. Such wide sockets are the cause of the offsetting at each joint wherever they are laid. These jogs, or off-sets, collect solid matter in a sewer, and, of course, retard the flow very much. When small openings are used, such as can be made with cement pipe, this difficulty is entirely eliminated and a close and smooth joint is the result. In many places no cement at all is required in the joint as the slit in the sewage quickly fills up the small opening.

In many sections of the country vitrified pipe can only be shipped at great expense, and, wherever under such conditions, concrete materials can be obtained, it is far cheaper to make sewer pipe of cement. In many places of Europe, where there are no clay deposits, concrete sewer pipe has been used for years without any question whatever as to its suitability for sewer purposes.

Durability.—In 1877, when Julius W. Adams, Past-President of the Am. Soc. of C. E., was chief engineer of the city of Brooklyn, there was a proposal made that the use of earthenware pipe should be resumed. This proposal was adversely reported upon by Mr. Adams. The following are some quotations from his report:—

"Last winter there were careful inspections made of our pipe sewers. In one sub-division the grades of streets are over two-and-a-half feet to the one hundred, and a special examination was made of the pipe in this sub-division. There is no sign of disintegration or wearing away of the cement pipe. These pipe have been laid over five years. On the 25th of March, 1873, this department took up a cement pipe that had been laid in Fleet Street in the year 1861, and the pipe was found, in every particular, as good as when laid." . . . "The fact remains, however, that the renewals of sewer pipe in Brooklyn, on account of breakage or collapse, have been relatively less in the case of concrete than in that of earthenware pipe."

Since the above was written many more miles of cement pipe have been laid, and, as stated earlier in this paper, over 400 miles of cement pipe are in use in Brooklyn. The experience of Mr. Adams has been confirmed since that time. The cost of maintaining concrete sewer pipe has been proven to be less than that of vitrified pipe. This includes renewals, due to breakage, action of acids, and so on. It might be of interest to note that a few years ago, during the construction of the subway in Fulton Street, Brooklyn, more of the Fleet Street sewer pipe, referred to by Mr. Adams, was taken up and was found that it would be still good for a long time. The sewer was then about 50 years old. A few lengths of this pipe are in our possession. It is manufactured of natural cement, Cow Bay sand and gravel.

The main argument against the use of concrete pipe is that it cannot withstand the effect of sewerage, nor resist the action of acids. In Brooklyn but two cases have been called to our attention where there has been a failure of cement pipe, due to concentrated acids being admitted in the sewers. Inasmuch as such sewers have been existence for so many years, the percentage destroyed is entirely neglegible. The author desires, at this point, to make the statement, as an engineer, that if it is desirable to install a sewer which is to take concentrated acid discharges from manufacturing concerns, he would not advocate the use of cement pipe; but would suggest, for such conditions, vitrified pipe of the best quality, with joints of some asphaltic or acid resisting nature and that manholes be built of some other material than brick, laid in cement, because strong acids effect only cement, not bricks. It seems to be folly to dwell upon such a contingency. No manufacturer is going to be so extravagant as to permit highly concentrated acids to be wasted. They are too valuable.

Mr. Adams, in his report of 1877, says:—

"There has been considerable written about the acids acting injuriously upon cement pipe, but these acids in sewerage matter are greatly diluted, and I am convinced by the experience in this city that they will seldom destroy a good cement pipe. We have known of no case in this city where the street sewer has been disintegrated or eaten away by sewer acids or gases."

Mr. A. J. Provost in "Municipal Journal and Engineer," vol 20, page 388, says:—

"The argument advanced against concrete sewers is still confined to possible disintegration by acids. The fact remains, however, that the renewals of sewer pipe in Brooklyn on account of breakage or collapse have been relatively less in the case of concrete than in that of earthenware pipe."

Mr. Rudolph Hering, consulting engineer, in a report dated February 15th, 1908, to Honorable Bird S. Coler, President of the Borough of Brooklyn, says.—

"Portland cement used for the manufacture of concrete pipes is attached by certain strong acids, such as sulphuric acid, which converts the carbonate into sulphate of lime, otherwise called gypsum, which is comparatively soft and easily corroded. Therefore, cement pipe cannot be used where strong acids are known to enter the sewers.

"Vitrified pipe will stand the effect of most acids. When the joints are made of cement these will, of course, be acted upon by acids as readily as the cement pipes.

"It should be added that the acid question should be viewed in a reasonable light. When the dilution of sewage is sufficient the discharge of a small amount of even the strong acid will not cause objectional effects as evidenced by European cities where the use of concrete sewers is almost exclusive in some cities, as Paris and Vienna. In England concrete sewers are also very common. Strong acids attack not only cement, but brick. Yet bricks are extensively used both in America and in Europe for building large sewers, where naturally any acid would be very dilute.

"The greasy substance which is usually found to coat the perimeter of a sewer under the water-line tends to protect the cement from the action of acids to some extent.

"It should be added that just as it is objectionable to discharge exhaust steam into sewers and the waste from gas works, which many cities prohibit, so it should be prohibited to discharge strong acid waste into the same."

The Joint Committee on Concrete and Reinforced Concrete of the American Society of Civil Engineers, American Society for Testing Materials, American Railroad Engineering and Maintenance of Way Association, and the Asociation of American Portland Cement Manufacturers, in its report presented at the annual meeting of the American Society of Civil Engineers, January 20, 1909, says:—

"Concrete of first-class quality, thoroughly hardened, is affected appreciably only by strong acids which seriously injure other materials. A substance like manure, because of the acid in its composition, is injurious to green concrete, but after the concrete has thoroughly hardened, it satisfactorily resists such action."

Much more could be written about the advantages and durability of cement pipe, but it would be largely reiterating what has been already written about it by others and

enumerating the many places both in Europe and America where cement pipe has been in use for many years.

The author has positive knowledge that over 400 miles of such pipe laid during a period of over 50 years are giving eminent satisfaction in Brooklyn and in his opinion all arguments against its suitability for sewers are answered by that fact.

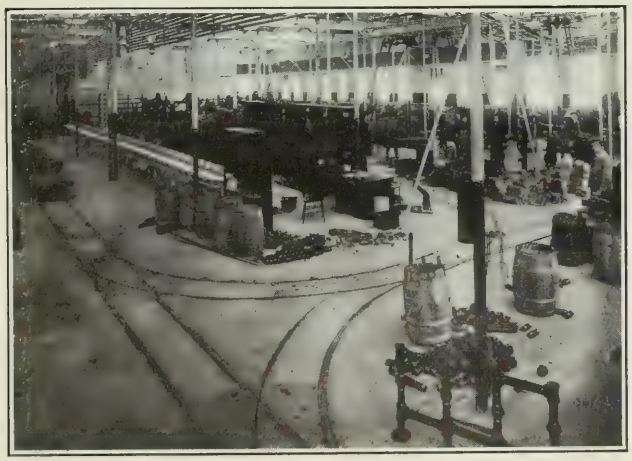
NARROW GAUGE RAILWAY INSTALLATIONS.

Narrow gauge railway systems are applicable to every industry and service where the reliable movement of material is essential and where large initial loads are moved irregularly and intermittently.

Such a system, as a production factor, can and should be judged in much the same manner as the productive tools and machines; that is, by balancing the time and labor saving, general convenience and efficiency increase on other tools against maintenance expense and interest on original investment.

The economies obtainable are best evidenced by use and continued extension of such systems in many power plants, foundries, machine shops, paper mills, textile mills, fertilizer works, chemical works, quarries, steel mills, gas works, powder mills, railroad yards, smelters, mines, coaling stations, brick works, wood shops, warehouses, etc.

A shop railway system without provision for power on the cars can be profitably applied almost wherever the movement of material, either finished or raw, or both, is done by hand truck or wheelbarrows, and averages three or more tons per day. One man, for instance, with a shop car, should easily be able to move on level track, a one-ton load that could not be handled in the same time with wheelbarrows by five men. With cars operated electrically from storage batteries, trolley or third rail, the loads that can be carried are limited only by the strength of the cars and track.

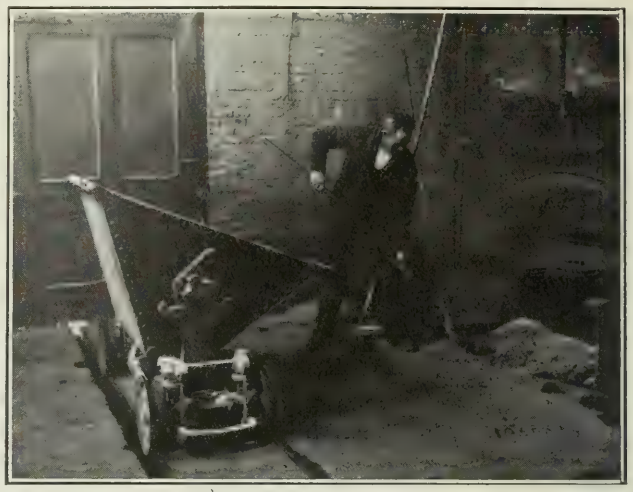


System Using Flat Top Cars in Machine Shop and Shipping Department. Utica Drop Forge and Tool Co., Utica, N.Y.

The loads on cars can generally be apportioned according to requirements up to a maximum car load of about 10 tons, a load distribution of one to three tons per car, under average conditions being very effective.

A railway system involves no expense when not in use, and is immediately available for peak loads. The car platforms can be adapted in size and height to best suit the carrying conditions as well as for ease of loading and unloading. Where desirable, the material may be kept on the car during manufacturing processes, the car being used as a platform and thus saving the labor of rehandling. Accurate weight of material while on the cars is easily obtainable by putting platform scales at any convenient point in the track system.

That a system of cars and tracks can be a profitable investment, is easily computed for any given conditions. As a rule, the labor saving alone justifies the installation.



Tip Car for Handling Ashes, Etc., Stevens and Thompson, Hoosick Falls, N.Y.

Suppose, for instance, the railway in a factory saved the wages of a boy at seventy-five cents a day. This saving of $225.00 per year alone would pay fifteen per cent. interest on an investment of $1,500.00. It would be hard to imagine a place where so large an expenditure could be made for a system of cars and tracks without effecting much greater net savings.

It is not uncommon for a shop railway system to save its entire first cost during the first year of its operation, and it would be a most unusual case where the direct saving each year would not equal one-third of the entire cost of the installation.

Not only is a direct saving of labor accomplished, but the facilitated manufacturing operations do much toward hastening deliveries, and frequently a more economical shop lay-out is made possible.

A narrow gauge railway system can be laid out by the shop manager, superintendent or anyone familiar with the points to be reached. There is seldom any part of a plant or building to which the tracks cannot be extended, and if the system is properly laid out there should be no inconvenience in getting the cars from any one point to any other on the lines. The track can usually be laid on any form of floor or road bed, and can be run across or between standard gauge railway tracks without cutting the rail heads. Any requirement of easily crossing rails with hand trucks or other vehicles can be met by filling in around or inside the tracks with concrete, boards, etc.

The illustrations show a few practical applications to various industries based upon the Hunt Industrial System, the parts of which are manufactured by the G. W. Hunt Company, West New Brighton, N.Y. In this system, the standard gauge of track is 21½ inches measured from outside to outside of rail heads and loaded cars of standard width require a passage of four feet clearance. Track and cars of other gauge are, of course, usable, as the conditions

may demand. The track sections, switches, frogs, cross-overs, etc., are made up on the interchangeable sectional unit plan, much the same as are modern filing cabinets. Any workman of ordinary intelligence can put the sections together and get the whole system ready for use. Should the movement of material change or extensions be required, this unit system of construction lends itself in a most flexible way to such changes or additions. Equipment of cars can also be made standard and interchangeable, which effects great convenience and economy.

A valuable feature of the Hunt System is the employment of a flexible running gear and outside flanged wheels on the cars and a special construction on the outer rail of curves, by means of which, as claimed by the manufacturers, a loaded car runs around a curve of as small a radius as 18 feet, as safely and requiring as little power as on straight-way. It is evident that with such flexibility of the system, the cars of a narrow gauge railway can reach any point that could be reached by trucks and wheelbarrows, including the movement of cars to different floors by elevators.

THE CHEMIST AS AN AID TO EFFICIENCY.

The industrial chemist points the way to great increases in efficiency, particularly in the item of buying supplies, according to Mr. Arthur D. Little, president of the American Chemical Society. In a paper on "The Chemist in Manufacturing," he says:

Chemistry points out the only proper way to buy supplies, which is on the basis of their industrial efficiency by means of specifications defining the quality desired and rigid tests to make sure that quality is secured. Independent estimates by those in exceptional positions to know place the efficiency value of supplies as purchased and used by American manufacturers at 60 per cent. of what it should be. .. ..

Similarly the industrial chemist has a large control over the efficiency of labor. He may increase this efficiency, that is, the output of the individual laborer, by supplying more efficient processes, as Bessemer did in case of steel, Tennant in case of bleaching, or Le Blanc and Solvay in the manufacturing of alkali. He may raise the efficiency of the laborer through education, as when firemen are instructed in proper firing methods or when cooks in the sulphite pulp mill are given boiling schedules; in one instance within our knowledge such schedules raised the efficiency, not of the cooks alone, but of the entire plant as well, over 50 per cent.

Nowhere has the industrial chemist greater scope for the effective exercise of his trained and organized common sense than in the control of processes and the elimination of wastes, and nowhere are the results he has already obtained more valuable. Their influence upon productive industry has been dramatic and profound. One need only point out that the whole art of modern steel-making is under the strictest chemical control, and quote Carnegie to the effect that it has been revolutionized thereby. No industry affords a better example of the value of such control or furnishes more striking instances of the profitable utilization of wastes. The conversion of slag to cement and fertilizer, the development of 10,000 horse power from the waste gases of a single furnace, are but steps in the development which will soon make pig iron the by-product of the furnace which derives its chief revenue from the waste of yesterday. With the open-hearth furnace still utilizing less than 10 per cent. of the energy of its fuel, let no chemist think the door of opportunity has closed.

WATER-POWER BRANCH.

The Canadian Engineer learns of a recent change in the organization of the Department of the Interior at Ottawa, of particular interest to engineers—the creation of a water power branch and the appointment of Mr. J. B. Challies as superintendent. The new branch is charged with the responsibility of all matters connected with the administration of water powers in Manitoba, Saskatchewan and Alberta, and also of all matters relating to irrigation, reclamation and power in the railway belt of British Columbia. In addition to a head office organization at Ottawa, the new branch comprises an extensive corps of experienced field engineers, having headquarters at Winnipeg, Man.; Calgary, Alta., and Kamloops, B.C., engaged in reporting on water power projects and the investigation of the water resources of the west, with particular reference to power. These investigations are being carried on under the advice of prominent consulting engineers, and when completed will be furnished the profession in the form of blue books. *The Canadian Engineer* hopes to publish a full account of these investigations in subsequent issues.

The superintendent of this work is a graduate of the School of Practical Science, class 1903, and an associate member of the Canadian Society of Civil Engineers. Mr. Challies' many friends will be glad to learn of his selection for this important work.

PERSONALS.

MR. JOHN W. EBER has been appointed superintendent of the Toronto, Hamilton and Buffalo Railway in succession to Mr. H. H. Adams.

MR. A. S. ANDERSON has been awarded the Boiler and Inspection Co. scholarship for general proficiency in the Department of Mechanical Engineering of the University of Toronto Faculty of Applied Science.

DR. J. W. S. McCULLOUGH, chief health officer for the province of Ontario, will be the provincial representative at the International Congress on Hygiene and Dermography, which meets at Washington during the late summer.

MR. A. W. GRAY, formerly county roads superintendent in Frontenac, Ont., will be made assistant provincial engineer of highways, and MR. ARTHUR SEDGWICK will, according to report, be appointed second assistant engineer of the Provincial Highway Department.

OBITUARY.

MR. EDGAR CHAPMAN, a mining engineer of New Liskeard, was found dead in his berth on the North Bay Grand Trunk Railway train. Mr. Chapman was connected with the Casey-Cobalt mines, north of New Liskeard. Two months ago his wife predeceased him after an illness of nearly three years. He was on his way to Toronto to spend the week-end with his daughter.

MEETINGS.

The Regina Engineering Society held their inaugural dinner at the King's Hotel on the evening of May 2nd last. Sixty-five members and guests sat down. After the usual toasts were proposed, the toast of "Canadian Industries" was proposed by Mr. Thornton, who pointed to the dependence of the success of our industries on the engineering

profession. Canada's now world-wide industrial reputation must be upheld largely by her engineers.

Mr. Haggarty replied by drawing attention in particular to Saskatchewan's possibilities for industrial development.

An address on "The Future of the Engineering Profession in the West" by A. J. McPherson followed. The speaker spoke of the growing importance and variety of these industries to our national life. The engineering profession has a wide field in the development of Canada's coal, forest and water power resources, as well as in the solving of the many engineering problems of our new cities.

In all these matters the responsibility and opportunity of the profession are of the very greatest.

"Our Railway Systems" was proposed by Mr. Martin, who spoke of the place of engineers in the forefront of every problem of transportation, of water power, of water supply, and of all other problems affecting national welfare. Saskatchewan, he said, offered alluring opportunities for the engineer because of her great and as yet but barely developed resources, and the engineering problems they present. The railroads are one of the most important factors in this development and the engineer has a broad field of usefulness open to him in railway work.

COMING MEETINGS.

INTERNATIONAL RAILWAY FUEL ASSOCIATION.—May 22nd-25th. Annual Convention at Chicago, Ill. Secy., D. B. Sebastian, La Salle St. station, Chicago.

FOURTH NATIONAL CONFERENCE ON CITY PLANNING.—May 27th-29th. Meeting, Public Library, Boston, Mass. Sec'y, Flavel Shurtleff, 19 Congress Street, Boston, Mass.

AMERICAN WATER WORKS ASSOCIATION.—June 3rd-8th. Annual Convention at Louisville, Ky. Secy., J. M. Diven, 271 River St., Troy, N.Y.

CANADIAN ELECTRICAL ASSOCIATION.—June 19th-21st. Annual meeting at Ottawa, Ont. Sec'y, T. S. Young, 220 King St. West, Toronto, Ont.

SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION.—June 26th-28th. Annual meeting at Boston, Mass. Sec'y, H. H. Norris, Cornell University, Ithica, N.Y.

ONTARIO MUNICIPAL ASSOCIATION —Annual convention will be held in the City Hall, Toronto, on June 18th and 19th, 1912. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ont.

CANADIAN PUBLIC HEALTH ASSOCIATION.—Second Annual Meeting to be held in Toronto, Sept. 16, 17 and 18.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE: Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, S. J. Chapleau, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving; Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, C. E. Cartwright; Secretary, W. Alan, Kennedy; Headquarters: McGill University College, Vancouver.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1290.

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydonejack; Meets every first and third Friday of each month, October to April, in University of Manitoba, Winnipeg.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION.—President, Chas. Hopewell, Mayor, Ottawa; Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm. Mason, Bon Accord, Alta. · Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, W. Sanford Evans, Mayor of Winnipeg; Hon. Secretary-Treasurer, W. D. Lighthall, K.C., Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, Mayor Mitchell, Calgary.; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALTIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION. - President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont ; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, N. W. Ryerson Niagara Falls; Secretary, T. S. Young, Canadian Electrical News, Toronto.

CANADIAN FORESTRY ASSOCIATION —President, John Hendry, Vancouver. Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewit, General Manager Consumers' Gas Company, Toronto; J. Keillor, Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President, J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary. H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, D. McDonald, Manager, Montreal Street Railway; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council :—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, Killaly Gamble, 703 Temple Building, Toronto.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, J. E. Ganier, No. 5. Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA —President, F. S. Baker, F.R.I.B.A., Toronto, Ont.; Hon. Secretary, Alcide Chausse, No. 5. Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, J. P. McRae; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Wm Pierce, Calgary; Secretary-Treasurer, John T. Hall, Brandon, Man.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, 115 Phœnix Block, Winnipeg, Man. Second Monday, except June, July and August, at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc. Printed forms for the purpose will be furnished upon application.

PLANS AND SPECIFICATIONS ON FILE.

The following Plans (P.) and Specifications (S.) are on file for reference only unless otherwise noted at the office of The Canadian Engineer, 62 Church Street, Toronto:—

Bids close — Noted in issue of

5-15 Reinforced arch bridge, Guelph, Ont...(P. & S.) 5-2
5-25—Sanitary sewer, Islington, Ont. .....(P. & S.) 5-16
5-29—Water works, sewerage and electric light systems, Melfort, Sask. .....(P. & S.) 5-2
6-10—Electrical equipment, Vernon, B.C. .....(S.) 5-16

(Melfort plans and specifications are also on file at The Canadian Engineer Offices, 820 Union Bank Building, Winnipeg, and B33, Board of Trade Building, Montreal).

(Vernon specifications are on file at The Canadian Engineer Offices, Winnipeg and Montreal; Canadian Electrical News, Toronto; Contract Record, Toronto; Mather, Yuill & Company, Limited, Consulting Engineers, Vancouver, B.C.)

TENDERS PENDING.

TENDERS.

Broadview, Sask.—Tenders for the construction of a skating rink at Broadview, will be received by A. Sinclair, Town Clerk, up to May 27th, 1912. Plans, etc., at the office of the Town Clerk, Broadview, or office of architect, Hugh G. Holman, 11-12 Jordan Building, Winnipeg.

Edmonds, B.C.—Tenders for the construction of an extension to Reservoir No. 1, in D. L. 189, for the municipality of Burnaby, will be received until Monday 20th, 1912. Particulars may be obtained at the office of the Engineers, Cleveland and Cameron, 506 Winch Building, Vancouver. W. Griffiths, Comptroller, Edmonds.

Edmonton, Alta.—The City Commissioners are inviting tenders for grading and the construction of boulevards on six miles of residential streets, work to be put in hand at once.

Guelph, Ont.—Tenders will be received up to May 18th, 1912, for the erection of a factory building at Guelph for the Dominion Linen Mfg. Co., Ltd. Particulars at the office of Colwill, Tanner & Co., architects, Traders Bank Bldg.

Hamilton, Ont—Tenders for supplying the Corporation of the city of Hamilton with two units of synchronous motors for direct connection to turbine pumps with transformers, switching apparatus and accessories complete, also for two units of turbine pumps, each of a capacity of 6,500,000 imperial gallons per 24 hours, for direct connection to synchronous motors, will be received until June 3rd, 1912. Specifications at the office of the City Engineer. (See advt. in Canadian Engineer).

Islington, Ont.—Tenders will be received until May 25th, 1912, for the construction of a 6 and 10-inch sanitary sewer on Fifth and Morrison Streets, New Toronto, from the northerly limit of Lot 392, plan 1692, on Fifth Street to the centre of Morrison Street, and easterly on Morrison to main sewer on Fourth Street. Plans, etc., at the office of The Canadian Engineer, Toronto, and J. A. L. Macpherson, Clerk and Engineer, Islington, Ont. (See advt. in Canadian Engineer).

Kerrisdale, B.C.—The council for the corporation of Point Grey is prepared to receive tenders for fire fighting apparatus for the municipality to be in by 5 p.m., Monday, May 27th, 1912. H. Floyd, C.M.C., Kerrisdale.

London, Ont.—Tenders will be received at the office of the City Clerk until noon May 18th, 1912, for the construction of cement walks in the city of London. Specifications at the office of the City Engineer. (See advt. in Canadian Engineer).

Montreal, P.Q.—Tenders for the supply and delivery of the following general supplies and various materials required for the different departments of the municipal service during the year 1912-1913, will be received up to noon of May 21st, 1912, by L. N. Senecal, secretary, Commissioners' office, City Hall, Montreal:—1. General supplies, macadamizing stone, and screenings, inorganic dust, lead pipe, pig lead, ingot tin and bituminous and anthracite coal, lumber, brick, vitrified clay pipes and inverts, hardware, spikes, paints and oils, lubricating and burning oils, iron and brass castings, gullies, pitch, coal, tar, dualine, detonators, fuse, street names and house numbers and sundry other materials. 2. For the purchase of scrap iron, steel, brass, copper, zinc, rubber, leather, waste paper, etc., etc.

Moose Jaw, Sask.—Tenders for water work fittings will be received by the City Commissioners up to noon on May 30th, 1912. (See advt. in Canadian Engineer).

Moose Jaw, Sask.—Tenders for the erection of a concrete retaining wall and laying of a number of new sidewalks at the Collegiate grounds, will be received up to June 5th, 1912. Specifications to be seen at the Collegiate Institute. Clifford Kempton, secretary-treasurer.

Ottawa, Ont.—The Department of Public Works will receive tenders until June 4th, 1912, for the construction of a wharf or retaining wall at Owen Sound, Grey County, Ont. Plans, etc., at the Department; office of J. G. Sing, District Engineer, Confederation Life Building, Toronto; H. J. Lamb, District Engineer, Windsor, Ont., and on application to the Postmaster at Owen Sound, Ont.

Ottawa, Ont.—Tenders for the design and construction of the new steamship for Hydrographic Service for the Atlantic Coast, will be received up to noon of June 30th, 1912, at the office of G. J. Desbarats, Deputy-Minister of the Naval Service, Department of Naval Service, Ottawa. (See advt. in Canadian Engineer).

Ottawa, Ont.—The Department of Public Works, Ottawa, will receive tenders for the construction of a wharf at Fredericton, York County, N.B., up to June 4th, 1912. Plans, etc., at this Department; office of J. K. Scammell, Esq., District Engineer, St. John, N.B.; Geoffrey Stead, District Engineer, Chatham, N.B.; and on application to the Postmaster at Fredericton, N.B.

Ottawa, Ont.—Tenders for the reconstruction of an approach to the Government wharf at Sault Ste. Marie, Ont., will be received up to June 4th, 1912, plans, etc., of which may be seen at the office of the Department of Public Works; J. G. Sing, District Engineer, Confederation Life Building, Toronto; H. J. Lamb, District Engineer, Windsor, Ont.; on application to the Postmaster at Sault Ste. Marie, Ont. R. C. Desrochers, secretary, Department of Public Works, Ottawa.

Pembroke, Ont.—Tenders will be received by the Town Clerk, up to noon of May 18th, 1912, for the construction of a Carnegie Library, Pembroke, Ont., according to plans and specifications prepared by Francis C. Sullivan, Architect, Castle Building, Ottawa, which may be seen at the office of the Architect, or Town Clerk's office, Pembroke. A. J. Fortier, Town Clerk.

Pincher Creek, Alta.—Mr. G. D. Plunkett, secretary-treasurer of the town of Pincher Creek, will receive tenders for the erection of a municipal building until Monday, May 20th, 1912. Plans, etc., at the Builders' Exchange, Lethbridge; office of the town clerk, Macleod; secretary-treasurer, Pincher Creek; the architect, James A. Macdonald, Room 8, Dominion Block, Calgary, Alta.

Saskatoon, Sask.—Tenders for the erection and completion of an eight-room school building to be built for the town of Melfort, Sask., will be received up to noon of May 29th, 1912. Plans, etc., at the Winnipeg Builders' Exchange, and at the Saskatoon Builders' Exchange, also office of W. Wood, Melfort, Sask., and office of the architect, W. W. Lachance, top floor, Willoughby Block, Saskatoon.

South Nelson, N.B.—Tenders for the construction of a stone Court House with municipal offices, to be built in Newcastle, N.B., will be received until May 20th, 1912. Plans and specifications may be seen at the office of the County Secretary, P. Williston, Esq., Newcastle, or at the office of the architect. G. Percival Burchill, chairman of committee, South Nelson, N.B. Leslie R. Fairn, architect, Aylesford, N.S.

St. Lazare, Man.—Tenders for the construction of a bridge over the Qu'Appelle River at St. Lazare, according to plan from the Department of Public Works, Winnipeg, will be received up to May 24th, 1912. Henry Tillman, secretary-treasurer, St. Lazare, Man.

Toronto, Ont.—Tenders for the erection of a lock-up at South Porcupine, will be received up to Wednesday, May 22nd, 1912. Plans and specifications at the office of Cook & Mitchell, barristers, in South Porcupine, and at the Department of Public Works, Ontario. H. T. McNaughton, Secretary, Department of Public Works, Toronto.

Toronto, Ont.—Tenders for the supply of cast-iron penstocks for the high level interceptor, will be received up to noon, Tuesday June 4th, 1912. Plans and specifications at the office of the City Engineer. (See Advertisement in Candian Engineer.)

Toronto, Ont.—Tenders for storm overflow sewer main, Garrison Creek, section No. 2, will be received until noon of June 4th, 1912. Plans and specifications at the office of of the City Engineer. (See Advertisement in Canadian Engineer.)

Toronto, Ont.—Tenders will be received until May 25th, 1912, for the construction of a concrete arch bridge over Copelands Creek, between Concession 13 and 14, Township of Tiny, County of Simcoe. Plans and specifications at the office of Frank Barber, Civil Engineer, 57 Adelaide Street East, Toronto. (See advt. in Canadian Engineer).

Vernon, B.C.—Tenders for electrical equipment will be received by D. G. Tate, City Clerk, up to 3 o'clock p.m., June 10th, 1912. (See advt. in Canadian Engineer).

Victoria, B.C.—Tenders for the erection of a new schoolhouse at Scott Road, Delta district, will be received by the Public Works Department up to noon of May 22nd, 1912.

Winnipeg, Man.—Tenders for an apartment building on River Avenue, will be received up to Saturday, May 18th, plans and specifications of which may be obtained at the office of William Bruce, architect, 222 McDermot Avenue.

CONTRACTS AWARDED.

Brantford, Ont.—The contract for the new nurses' home has been let to Messrs. Secord & Sons here. The building will cost $36,000.

Calgary, Alta.—Messrs. Grant-Smith Company and McDonnell, of Vancouver, have been awarded the contracts for a million-dollar work on the irrigation block. This includes a concrete aqueduct to cost half a million, other concrete structures to cost $300,000, and thirty steel bridges to cost $100,000. The aqueduct, which is the first of its design to be constructed, will be 10,500 feet long, with a maximum height of 55 feet and will irrigate 100,000 acres of the Canadian Pacific block.

Calgary, Alta.—The contract for the construction of the machine shop, foundry and office building, of steel, concrete and brick, for the Pioneer Tractor Company's plant, has been secured by T. F. Hook, of Calgary, and A. Groff, of Chicago.

Cobalt, Ont.—The town council has awarded the contract for laying sidewalks in the town at all town property to J. J. Anderson, whose bid was $25 a thousand. Several thousand feet of the walks will be laid, and the work is to be commenced at once.

Fredericton, N.B.—The contracts for supplies for water and sewerage work during the coming summer has been awarded as follows: D. J. Shea, soil pipe, at 25 cents per foot; J. S. Neill and Sons, terra cotta pipe, at 12 cents per foot; R. Chestnut and Sons were awarded the contract for supplying the galvanized iron and cement. J. L. Feeney, City Engineer.

Moncton, N.B.—The New England Artificial Stone Company of St. John was awarded a contract for thirty thousand dollars' worth of concrete sidewalks, crossings, etc., to be laid in Moncton this year. The tender ranged from 14½ cents for class A. to 16 cents for class D.

Montreal, P.Q.—Contracts approximating $100,000 for sewers and street improvements for the town of Outremont, have been awarded by the Outremont Town Council, as follows: Sewer awards to R. T. Smith and Company, Van Horne Avenue, from Rockland Avenue to Hartland Avenue, $3,544. Outremont Avenue, between Van Horne and Deschamp, $3,066. Sewer awards to Messrs. Gilbert & Payee: Wilder Avenue, $4,917. Wiseman Avenue, between Van Horne and

$Dolarway Pavement

"It is permanent because it is concrete."

The Last Word In Street Pavements

Dolarway Pavement is popular with City Officials and Property Owners because:

It is low in first cost.

Its maintenance cost is lower than that for any other permanent form of Pavement.

No paving plant is required to either construct or maintain it.

It is noiseless, dustless and resilient.

Its traction qualities for both the Horse and the Automobile are of the best.

For full particulars address

DOLARWAY PAVING COMPANY

95 Liberty Street, New York City 510 Title & Trust Bldg., Chicago, Ill.

Deschamp, $2,905. Lajoie, from Querbes to Outremont, $5,-850. Bloomfield Avenue, from Van Horne to Deschamp, $2,-905. Champagnier Avenue, between St. Viateur and Bernard Avenue, $5,505.75. Marsolais Avenue, $2,137. Sidewalks contract was divided into two sections, and the quantities were A 20,000 and B 17,000 lineal feet. "A" section was awarded to Messrs. Contractors, Ltd., at 25 cents per square foot, and "B" section to R. T. Smith & Co., at 28 cents per square foot.

Moose Jaw, Sask.—Messrs. Wilson, Townsend & Saunders, of Moose Jaw, have received the contract for the construction of a reinforced concrete subway under the C.P.R. Company's tracks on Eleventh Avenue. Cost, $82,464.89.

Vancouver, B.C.—The British Columbia Permanent Loan Company has closed a contract with the Norton Griffiths Steel Construction Company for the erection of a magnificent ten-story modern office building in Victoria.

Vancouver, B.C.—The British Columbia Electric Railway Company has let the contract for the construction of the grading on its line on Nanaimo Street from Hastings Street to Broadway, to Messrs. Franklin and Shepherd. Messrs. Franklin & Shepherd have also received the contract for the grading preparatory to the double tracking on Fraser Avenue, South Vancouver.

Vancouver, B.C.—Messrs. M. P. Cotton & Company and the Canadian Mineral Rubber Company secured the largest share of the asphaltic mixture pavement contracts awarded by the board of works. Out of a total of 265,289 yards, covering sections of twenty-six streets, M. P. Cotton & Company obtained 100,000 square yards and the Canadian Mineral Rubber Company a like amount. T. R. Nickson & Company received 17,500 yards and the Columbia Bitulithic Company 15,000 yards. The former tendered on sheet asphalt and the latter on bitulithic. A balance of 32,789 yards was left over for future consideration. The amount represented in the laying of this amount of pavement will total almost $1,000,000.

Winnipeg, Man.—The contract for the bridge at St. Andrew's locks has been awarded by the Dominion Government to the Brown Construction Company, Limited, of Winnipeg. The contract calls for a bascule lift span operated by electricity which opens and shuts to allow boats to pass up and down the river. There will be upwards of 500 tons of steel required to complete this work as well as 25,000 cubic yards of concrete. The contract has to be completed in fifteen months. The contract price approximately is $150,-000.

Winnipeg, Man.—The contract for the erection of twelve additional rooms to the Britannia School was awarded to J. Dolmer, contractor, Winnipeg, for $88,900. E. D. Tuttle, Architect, 701 McArthur Building, Winnipeg.

Winnipeg, Man.—Two deep well turbine pumps: Messrs. Stuart Machinery Co., Winnipeg, at $4,575 each.

RAILWAYS—STEAM AND ELECTRIC.

Brandon, Man.—The buildings and plant of the Maple Leaf Milling Company at this point were destroyed by fire on May 10th last. The loss is estimated at $40,000.

Montreal, P.Q.—A report states that the management of the Grand Trunk Railway have recently placed freight car orders as follows:—1,000 box cars with the Western Steel Car and Foundry Company, of Chicaga; 2,000 box cars with the Canadian Car and Foundry Company, of Montreal; 250 auto cars with the American Car and Foundry Company, of Detroit; 250 auto cars with the Western Steel Car and Foundry Company, of Chicago; 250 refrigerator cars with the American Car and Foundry Company, of Detroit; 250 refrigerator cars with the Canadian Car and Foundry Company, of Montreal; 1,000 new steel hopper bottom coal cars with the Pressed Steel Car Company of Pittsburg.

Montreal, P.Q.—A report states that the Canadian Pacific Railway Company has ordered 250 new engines and 12,-500 box cars. It is altogether likely this is the largest amount of rolling stock ever placed on order at one time in this country.

Prince Albert, Sask.—Work was commenced on May 6th on the survey of the Canadian Northern Railway Hudson Bay road from this city.

Smiths Falls, Ont.—The Canadian Pacific Railway will commence construction work on a foot subway to accommodate traffic on that street. It will be 110 feet long, 10 feet wide, and seven and a half feet high, and will be built of white tile. It will be brilliantly lighted by day and by night, and will be maintained by the company except for the lighting, which will be done by the town.

St. Catharines, Ont.—Negotiations have been commenced to construct a belt line in connection with the lines of the Niagara, St. Catharines and Toronto Railway. It is reported that an extension of this railway to Niagara-on-the-Lake is contemplated.

York County, Ont.—The management of the Toronto & York Radial Railway will place sixteen new cars on their line during the coming season.

LIGHT, HEAT AND POWER.

Galt, Ont.—During the first eleven months' operation of the Hydro-Electric Department in Galt the financial statement shows the department to have made $7,510, a net profit for the town. In order to complete the ornamental and bracket lighting of the town, making extension of power and light and other services, the Hydro-Electric Commission finds that $45,000 more will be required to equip this work.

Medicine Hat, Alta.—The ratepayers will be asked to vote on June 3rd next to decide a by-law calling for the expenditure of $50,000 on electric light improvements, and $75,000 for extension of the gas system.

Moose Jaw, Sask.—The municipal superintendent of electrical matters has prepared drawings for a new ornamental lighting standard. It is materially different from those now in use, inasmuch as the first two lights are on arms elevated from the side of the post, while the second pair are immediately above the lower ones, but not extended as far from the post centre. The fifth light surmounts the standard.

Northern Ontario.—Five more towns in the northern part of the province will be served by the Hydro-Electric Power Commission—Barrie, Stayner, Collingwood, Coldwater and Elmvale. Preliminary estimates have been submitted by the commission to the town of Barrie for a supply of power under contract between the commission and the Simcoe Railway & Power Co., developing at the Big Chute Falls on the Severn River. An extension of the lines built by the commission supplying Midland and Penetang will be made to the five new municipalities in the Hydro-Electric belt. Final estimates will be submitted to these towns in the course of a week or two.

Regina, Sask.—The equipment at the power house will be materially increased within the course of the ensuing year. Provision has been made for the purchase or a street railway unit similar to the one already in use. Although extensions were made to the lighting plant during the early part of the present year, it will be necessary to purchase still another large lighting unit. It will be installed early in 1913.

Saskatoon, Sask.—As a result of the investigation of the conditions and possibilities of developing power on the South Saskatchewan, below the city of Saskatoon, H. M. E. Evans, head of the Saskatoon Power Company, has reported to the city council that 14,000 horsepower could be generated at a total construction cost of $2,200,000. The cost includes the electrical equipment for delivery of power to the city limits.

The estimate was made by a party of engineers from Stone & Webster, Boston, Mass. The original estimate of Canadian engineers was 4,000 horsepower at a cost of $866,-000. On the basis of those figures an agreement was entered into by the city with the company to buy the entire output at $33 per horsepower delivered.

GARBAGE, SEWAGE AND WATER.

Province of Saskatchewan.—A report states that the Government of Saskatchewan, the Canadian Pacific, the Canadian Northern and the Grand Trunk Pacific railways have entered into a compact to divert the south Saskatchewan River to supply drinking water to Regina, Moose Jaw, Weyburn

and other towns and cities in Saskatchewan. The work will cost ultimately $20,000,000.

Mr. T. Aird Murray, C.E., of Toronto, is the consulting engineer and a member of the commission.

Vancouver, B.C.—A waterworks by-law will be placed before the ratepayers at an early date. This is for the purpose of raising funds to complete the laying of a water main into the district of Point Grey. The first expense for the city in connection with this by-law will be about $175,000.

BUILDINGS AND INDUSTRIAL WORKS.

Athabasca Landing, Alta.—A deputation from this town has been in Ottawa to secure pulpwood concessions and authority to erect a pulp mill at this point. It is claimed that there is a great deal of suitable materials and abundance of natural gas. Mr. James Wood, of Athabasca Landing, is interested in the project.

Battleford, Sask.—The Overland Manufacturing Company of Vancouver, will establish a plant in Battleford for the manufacture of doors, sash, and all kinds of woodwork.

Calgary, Alta.—Mr. Russell, formerly chief engineer of the Temiscaming and Northern Ontario Railway, and Mr. Wilson of Saskatoon, have approached the new Industries' Committee, with a view of establishing a sand, lime, and pressed brick plant on one of the city's industrial sites. They guarantee that if they could secure a suitable site they would put in a plant of $100,000 and employ about 40 men.

Cobourg, Ont.—The ratepayers will vote on a by-law calling for the exemption of The Canadian Ohio Motor Car Company from taxation, excepting school taxes, for ten years and to grant the company a sum not exceeding $1,000 for the purchase of a site. Mr. H. I. Matthews, Lakefort, has been elected president and managing director.

Eastern and Central Ontario.—The Commissioners of the National Transcontinental have prepared plans for the construction of six 200-ton mechanical coaling plants with sand houses and track approaches at the following points on the line: Moncton, N.B.; Napadogan, N.B.; Edmunston, N.B.; Grant, Ont.; Calvert, Ont., and Armstrong, Ont. A 1,000-ton coaling station with inclined trestle approach is also planned at Cochrane, Ont. Tenders for all these plants are now being called for.

Fort William, Ont.—Mr. A. E. Fenton will construct an elevator with storage capacity of 35,000 bushels. It is reported that this is the forerunner of fifteen others of a similar type to be erected in the near future.

Galt, Ont.—Preparations have been made for the construction of a drill hall in this town to cost about $15,000. It is to be 80 × 130.

Goderich, Ont.—The Canadian Pacific Railway will commence building operations on a new flour storage building to cost about $20,000. It is to be 200 × 40 and entirely of wood construction.

Lindsay, Ont.—A site has been selected for the new armory building, and it is probable that building operations will be commenced at an early date. Captain H. Hughes, Cd. Engineer, R.C.E., of Kingston, selected the site.

London, Ont.—The management of the Dominion Abattoir Company will erect a $75,000 building. Mr. E. Rechnitzer is at the head of this company.

Moose Jaw, Sask.—Plans for Moose Jaw's first skyscraper have been prepared, which is to be built by the real estate and automobile firm of Manley, Loney and Company. The building is to be erected at the corner on Athabasca and Main Streets. It is the intention to build the first two stories of the building this year, and the foundation will be built to carry a ten-story building. The building is to be reinforced concrete, and the Turner system is being considered. It will have an imposing front on Main Street, and the foundation will cover an area of 54 feet by 125 feet.

Moose Jaw, Sask.—The Board of Education have passed a by-law calling for $65,000 to be raised for school buildings.

Moose Jaw, Sask.—The ratepayers will be asked to vote on a proposed expenditure of $25,000 for the completion of the public library.

Montreal, P.Q.—The Federal Government plan to erect a new postoffice in the district of Westmount during the coming summer. The cost of this work will be $100,000.

Port Arthur, Ont.—A report states that the Regina Trading Company will erect a three-story steel and office building to cost about $70,000. Messrs. H. W. Laird and Peacock, of Regina, are interested.

Regina, Sask.—A new civic building law has been presented to the council for consideration. Protection from fire is especially aimed at, and for this purpose the bill proposes that 125 feet or ten stories be the extreme limit of height in future buildings to be erected.

Regina, Sask.—The management of the Westman Agencies, Limited, have under construction a new six story building, 85 × 110. Messrs. Reilly, Dawson and Reilly are the architects. The cost of this will be about $140,000.

Saskatoon, Sask.—It is reported that the C.P.R. has purchased a plot of land in this city adjoining the Bank of Montreal, and on the site it is proposed to erect one of the best office buildings in the West, to be used largely by the different departments of the company.

Western Canada.—Ten small elevators of the Saskatchewan Co-operative Elevator Company are being established between Regina and Griffin, along the line of the Regina-boundary branch of the Grand Trunk Pacific.

West Vancouver, B.C.—The council of this municipality have had plans prepared for the erection of a new town hall. Mr. J. C. McKenzie is the designer of the building.

BRIDGES, ROADS AND PAVEMENTS.

Calgary, Alta.—The municipal council are considering plans prepared for a bridge to serve Crescent Heights and Sunnyside. The plans of this bridge shows the southern approach to be between First and Second Avenues, and the amount of cutting which would be done at the top of the hill would depend entirely what grade was desired. A grade of about 6½ per cent. would not require a very deep cut. Archways at the north side would allow traffic underneath, and the height of the bridge on the north side of the river would be about 50 feet. The cost of a concrete bridge of this design would be, according to present figures, about $780,000.

Medicine Hat, Alta.—Much publicity is given a report in this district to the effect that the Canadian Northern Railway will enter the city from Police Point. Should this be true a large bridge will be required to span the river.

CURRENT NEWS.

Calgary, Alta.—The municipal council are taking steps to secure information on a project which has for its object the formation of a civic coal supply and it is not improbable that this city will shortly be operating its own coal property and selling fuel to residents at a price only slightly in excess of the cost of production. The members of the council are practically unanimous in favor of a muncipally owned coal mine, which, as municipal affairs go, is an innovation.

Fort William, Ont.—The municipal Fire, Water and Light Committee have received a request from the chief of the Fire Department that he be furnished with a new steam engine and an auto chemical hose wagon. The cost of these will be $13,000.

Ottawa, Ont.—The Railway Commission have requested the Railway Board to enforce an order to the effect that existing regulations regarding locomotive draft control be abolished, and a new set drafted by the commissioners. These new regulations provide that all engines must be fitted with netting mesh to prevent the escape of sparks, and that every railway company must provide inspectors at terminal points whose duty it shall be to examine from April 1 to November 1 each year all locomotives in use.

The proposed regulations given the chief fire inspector or any authorized officer of the board the power to inspect locomotves at all times, and to reject those found to be defective in regard to the fire arrangements.

THE TRIPLEX BLOCK

A Triplex Block hung from a temporary rigging and used for laying pipe.

What is the Life of a Triplex Block?

WE don't know. Triplex Blocks built by the Yale and Towne Co. at the very beginning—twenty-five years ago—are still in actual use. The Triplex Block of to-day possesses greater lasting powers. With its steel parts—its chain superior to any other—its non-wearing gear movement—and the guarantee of a rigorous test before shipment under a fifty per cent. overload. It will outlast the man who buys it, no matter how young he may be.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from The Canadian Engineer for small fee.

16393—April 27—Directing C.N.R. to divert ballast pit track and clear shrubs and trees away at crossing known as Rosslyn Rd., Twin City Junction, Ont.

16394—April 25—Dismissing application of Trans. Bureau of Montreal Board of Trade re corn and cornmeal rates from Montreal to points in the Maritime Provinces.

16395—April 23—Refusing application of the Canadian Freight Assn. for revision of Order 6844, Apr. 6, 1909, re commodity rates on wire fencing and netting.

16396—April 23—Authorizing C.P.R. to construct its second track across Melville-Regina Branch of G.T.P. at Regina, Sask. Additional interlocking appliance to be installed.

16397-98—May 1—Authorizing C.P.R. to reconstruct bridge No. 7.3 and 17.0 on its Ingersoll and Sudbury S.D.

16399—April 27—Directing all express companies subject to Board to prepare tariffs or supplement to Express Classification showing a scale of charges for the return of the proceeds of C.O.D.'s upon other than "merchandise" rate basis, and file the same within three months from date of this Order.

16400—April 23—Naming express delivery and collection limits of city of Sydney, N.S.

16401—May 1—Authorizing village of North Red Deer to construct highway over tracks of C.P.R. at Cherry Avenue.

16402—April 30—Approving clearance of 18 feet for dump cars only into clay shed of Alberta Clay Products Co. by C.P.R. Siding at Medicine Hat, Alta.

16403—April 30—Extending until 31st August, 1912, time for completion of bridge across Shubencadie River at South Maitland, N.S., by Dominion Atlantic Railway.

16404—April 29—Authorizing Algoma Central & H.B. Ry. to construct bridge over Michipicoten River.

16405—April 20—Authorizing C.P.R. to construct siding for the Seaman, Kent Co., Ltd., town of Outremont, Quebec.

16406—April 29—Authorizing C.P.R. to reconstruct bridges 19.4 and 46.9 on Havelock and Megantic Subdivisions.

16407—April 29—Authorizing C.P.R. to construct an extra track across South Bay Road, Parish of Lancaster, Ct. St. John, N.B.

16408—April 30—Authorizing C.P.R. to operate its trains over Pacific Avenue, Fort William, and St. Railway account remodelling of interlocking plant completed.

16409-16410—April 25—Authorizing C.P.R. to construct spur for the Calgary & Western Lumber Co., at Bengal, Alta., and for the Canadian Sardine Co., at mileage 23.31 on St. Andrew's Branch, County of Charlotte, N.B.

16411—April 19—Providing for protection at crossing of Toronto Suburban Ry. and G.T.R. stock yards branch at Keele St. and St. Claire Avenue, Toronto.

16412-13—April 29—Authorizing G.T.R. to construct a track to connect with C.P.R. spur serving Standard Sanitary Mfg. Co., and to operate over said track in Toronto, and to construct spur for Steel and Radiation, Ltd., 6th Con., Twp. of Grantham, Ct. Lincoln, Ontario.

16414—April 29—Authorizing G.T.R. to reconstruct bridge No. 346 at mileage 198.03 on 6th District, Northern Division.

16415—April 30—Approving location of G.T.R. station at Rockwood, Ontario.

16416—April 29—Authorizing C.N.O. Ry. to construct across public road between Cons. A. and 1, Ottawa Front, Twp. of Nepean, Ont.

16417—April 29—Authorizing C.P.R. to construct spur line from its Swift Current Extension to serve Moose Jaw Clay Products Co., spur being 1.01 miles in length.

16418—April 29—Authorizing C.N.O. Ry. to construct over lead vein on the property of North American Smelting Co., Ltd., in Twp. of Loughborough, County of Frontenac, Ontario.

16419—April 29—16420—April 30—Authorizing C.N.O. Ry. to construct spur for W. J. Lawrence, village of Richmond Hill, Ont., and C.N.R. to construct spur for Newcastle Coal Co. at mileage 171.73, Alberta.

16421—April 30—Approving revised location of C.N.O. Ry. (Montreal-Port Arthur Line) in Twp. of Ross, Ct. Renfrew, mileage 62.09 to 66.19 from Ottawa.

16422—April 29—Approving location of C.N.O. Ry. through unsurveyed territory in Dist. of Thunder Bay, mileage 383 to 398 from Sudbury Junction.

16423—April 29—Approving location of C.N.R. through Twps. 26-28, Ranges 8-15, west 3rd M., Sask., mileage 0 to 49.59.

16424—April 30—Authorizing C.N.O. Ry. to cross forced road and township road in Twp. of Nepean, Ct. Carleton, Ont.

16425—May 2—Approving location of C.P.R. station at Weyburn, Saskatchewan.

16426—April 12—Approving location of Algoma Eastern Ry. Co.'s station at Espanola, in Twp. of Merritt, Ontario, Sudbury District.

16427—April 30—Approving Essex Terminal Railways Standard Tariff of Maximum Freight Tolls to apply between Walkerville and Windsor, Walkerville and Sandwich, and Windsor and Sandwich.

16428-29—May 3—Directing C.P.R. (Walkerton & Lucknow Ry.) to install electric bell at crossing of Hutton Hill Highway, Twp. of Bentinck, Ct. Grey, Ontario; and electric bell C.P.R. at Locust Hill, Ontario, within 90 days from date of these orders, 20 per cent. from Railway Grade Crossing Fund.

16430-31—May 2—Authorizing C.P.R. to construct and operate two spurs for T. S. Sims & Co., Ltd., at Fairville, N.B., and spur for George W. Upham, Parish of Southampton, Ct. York, N.B.

16432—May 2—Authorizing C.N.O. Ry. to cross Symes Road, Toronto.

16433—May 2—Authorizing C.N.O. Ry. to reconstruct bridges 24A and 24B crossing Kaministiquia River, at mileage 23.2 and 24.3, from Port Arthur.

16434—April 30—Authorizing C.N.R. to expropriate certain lands for road diversion and to file plans for overhead crossing; diversion or bridge to be completed before 1st September, 1912. Application, R. M. Kindersley, Sask.

Tenders Called For

THE CORPORATION OF THE TOWNSHIP OF ETOBICOKE.

TENDERS WANTED.

Sealed tenders, addressed to the undersigned, and endorsed "Tenders for Sewer," will be received by the Corporation of the Township of Etobicoke up to 3 o'clock p.m., the 25th day of May, 1912, for the following work, viz.:—

The construction of a 6 and 10-inch Sanitary Sewer on Fifth and Morrison Streets, New Toronto, from the northerly limit of Lot 392, plan 1592, on Fifth Street to the centre of Morrison Street, and easterly on Morrison to main sewer on Fourth Street. Plans and specifications may be seen at the office of the undersigned, or at the office of The Canadian Engineer, Toronto.

Tenders must be made on forms to be obtained from the undersigned, and must be accompanied by an accepted cheque for 5 per cent. of the amount of the tender, payable to the order of the Township Treasurer. The accepted cheque of the successful bidder shall remain in the hands of the Corporation until the work is satisfactorily completed.

The lowest or any tender not necessarily accepted.

J. A. L. MACPHERSON,
Clerk and Engineer, Islington, Ont.

Dated this 14th day of May, 1912.

BASSANO.

TENDERS FOR ELECTRIC GENERATING MACHINERY.

Sealed tenders, marked "Tender for Electric Generating Station Equipment," and addressed to S. E. Whiting, Esq., the Bassano Electric Power and Traction Company, Bassano, Alta., will be received by the undersigned at 6 p.m. of the third day of June, 1912, for the delivery and erection of the following machinery and apparatus:—

Section "A" Two Return Tubular Steam Boilers,
Section "B" One Steam Engine,
Section "C" One Electrical Generator and Equipment.

A marked cheque for 5 per cent. of the amount of the tender shall accompany each tender.

Tenders are invited for each section separately.

Specifications may be obtained from S. E. Whiting, Esq., Bassano, Alta., or from the Engineers, Messrs. Bowring & Logan, 322 Donald Street, Winnipeg, or may be seen at the office of Norman A. Hill, 43 Victoria Street, Toronto, or at the offices of The Canadian Engineer, 62 Church Street, Toronto, and 33 Board of Trade Building, Montreal.

BOWRING & LOGAN, Engineers, Winnipeg.
S. E. WHITING, President, Bassano.

(Tenders also on pages 72, 74 and 76).

RED DEER'S GROWTH.

April returns show the expansion in Red Deer, Alberta, continues. The building permits for the first four months of 1912 are $84,685, compared with $33,785 for 1911, which was a record for Red Deer up until that time. This is a gain of nearly two and a half times, or 250 per cent. Every department of business shows large increases. The passenger receipts are double those of April, 1911, and the freight, express, telegraph receipts have been very heavy. The local staff is rushed to handle their business, even with increased help.

In regard to customs, Red Deer was made a port of entry on April 1st, and the business done since then has shown the great need there was for such an office. At the rate of the business done since the office was opened, Red Deer will have more business during its first year than any port in Western Canada except Winnipeg. The receipts will be greater, too, than seven of the eleven western points up until two years ago, and will exceed that of several places of more than double Red Deer's population last year.

An Engineering Weekly

GRADE ELIMINATION AND BRIDGES.

By HENRY GRATTAN TYRRELL.

The subject of track elevation in the United States received but little attention until the year 1888, when the House of Representatives of Massachusetts appointed a commission to investigate and report on the subject of separation of grades for steam railroads and highways. The recommendations of the legislature were that grade crossings be eliminated, and that the expense of such work be borne

65% by the railroad companies
25% " " State.
10% " " local town or city.

In the two or three years following, the subject of grade elimination in Chicago was seriously considered, and in 1892 as a preparation for the approaching World's Fair in Jackson Park, Chicago, the Illinois Central Railroad undertook the raising of their tracks from Hyde Park to 72nd Street, Woodlawn, as in this district their tracks cross the principal avenues leading to the Fair Grounds.

In the same year a measure was introduced into the Chicago city council requiring a general raising of all the railroad grades entering the city. The population of Chicago was then about a million and a quarter, and there were 1,600 miles of track within the city limits, with 2,000 to 3,000 level crossings, over which upwards of 1,800 trains passed daily. The ordinance affected about thirty railroad companies, and required the elevation of 150 miles in line and the construction of 700 to 800 subways. So important an ordinance necessitating the expenditure of $75,000,000 or more, met with very serious opposition, and modifications were made requiring that parts only be elevated immediately, and the whole work spread over a period of years. A superintendent of track elevation was appointed, and portions of the work were soon commenced. The Chicago and Northwestern Railroad was one of those affected, and in the next few years portions of their various branches were raised, including about four miles of line on the Milwaukee branch between Diversey Boulevard and Balmoral Avenue, which was elevated in 1897. At a number of crossings in Chicago where the track is elevated on banks from 8 to 12 feet high, the streets beneath the tracks have been lowered from 4 to 6 feet, and graded back to the regular street lines. In Chicago and Evanston, it is impractical to depress the grades below the lake level, as provision for pumping would be necessary.

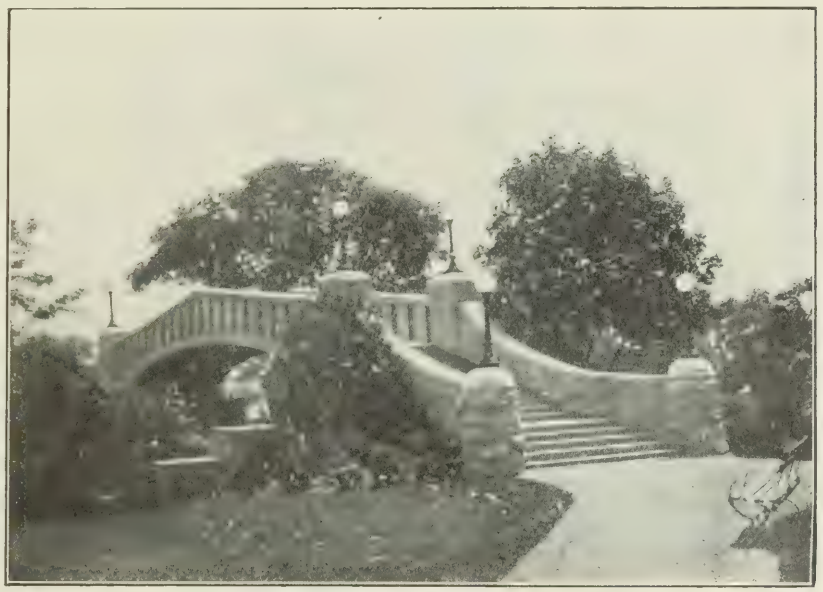

Fig. 1.—Forest Park Entrance, St. Louis.

This is an overhead bridge crossing when railway is depressed. It has a clear span of 50 feet, and spans two lines of track.

Evanston Work.—The method of track elevation used in Evanston is similar to that in Chicago, the country being all flat, and the grades insignificant. The city of Evanston, a residential suburb with a population of 25,000, lies directly north of Chicago, and the boundaries of the two municipalities meet. Two branches of the Chicago and Northwestern Railroad pass through the city, connecting with Milwaukee. In the morning and evening, during the hours of greatest travel, suburban trains run at intervals of three to ten minutes apart, averaging twelve per hour. Adjoining the steam railroad, are double tracks of the Northwestern Elevated Railroad, which is likewise elevated on an earth embankment, and where trains make stops at frequent intervals.

Grade removal was greatly needed, not only to avoid accidents, but also to make possible the running of faster trains between Evanston and Chicago. At some of the crossings several persons had been killed, and the fire risk was also increased by the level grades, because where trains are numerous fire engines might be delayed by them, and a few minutes' delay at the beginning of a fire might result in increased fire loss. Gates and flagmen are a partial protection but do not insure safety, as any provision depending on human watchfulness is sure, sooner or later, to prove disastrous.

*Consulting Engineer, Evanston, Ill. Mr. Tyrrell is a graduate of Toronto University in Civil Engineering of the class of 1886.

The general plan of track elevation in Evanston consisted in placing the steam railroad on an earth embankment, using retaining walls where the width of the railroad land was not sufficient for side slopes. At the street crossings, the bank was supported by abutments and the tracks carried over the streets on bridges, having three lines of columns in the streets, two at the curbs and one in the middle, dividing the street into right and left driveways. Travel was first diverted on a temporary track at one side of the permanent line, and pile trestles were then built on the permanent location over the streets and a sufficient distance at each side of the street to allow space for building the permanent abutments. In several places where the streets are fairly close together, the trestles were made continuous.

The railroad companies did all work at their own expense, unassisted by the city, and where street paving was removed for foundations, it was relaid by the railroad company. The driving of piles was carried on day and night with drop hammer pile drivers, and some Naysmith hammers making blows at intervals of two seconds. On the Melrose branch, only a part of the street crossings are bridged at present, the remaining ones where travel is light, being filled with earth banks, which can be removed and bridges substituted when the condition of travel demands it.

Much caution was needed in driving piles at the street crossings to avoid injuring the city sewers and water mains. When sufficient pile trestle work was built, sand filling was brought in by train and the bank made. The temporary side tracks were then removed and all travel turned over the bank and trestle. At several of the streets, when building abutment foundations, so much water was encountered that sheet piling was necessary. Two-inch tongue and grooved plank was used for this purpose and water pumped out of the excavations with hand pumps. Oak piles were driven in the excavations and were cut off three or four feet below street grade with hand saws.

Concrete was used almost exclusively for abutments and retaining walls, side walls being used only where the width of right-of-way is insufficient to hold earth slopes. Low walls are used in some cases near the toe of slope where enough land width was not available. High retaining walls are paneled on the face, but lower ones are plain, excepting for the presence of a coping. Vertical joints are left at distances of 15 feet apart for expansion. Little or no effort was made to remove form marks from the abutment faces, and these are very evident. Walls and abutments are of the solid gravity type, with backs stepped rather than sloped, and waterproofed with a coating of tar or asphaltum, which in many cases is not proving effective. Three lines of old rails are imbedded in the concrete, and at places where new walls are joined to old ones, a dovetailed joint is provided which not only permits expansion, but holds the two adjoining parts together.

Where the Northwestern Elevated Railroad adjoins the steam road, columns in the street correspond with those for the steam railroad bridges. The foundation in the centre of the street consists of a continuous wall pointed at the ends to serve as wheel guards, and standing a foot or two above the street level. On these walls are reinforced concrete columns, two under each line of track, with eight bars in each column, the four corner bars being larger than the others. At the depots are retaining walls between the steam railroad and the Northwestern Elevated Railroad, continuing far enough back from the street to form inclined driveways 24 feet wide, leading from the street up to the elevated grade. Stairways are built into the abutment faces at the depots, which lead up to the elevated platforms and shelters.

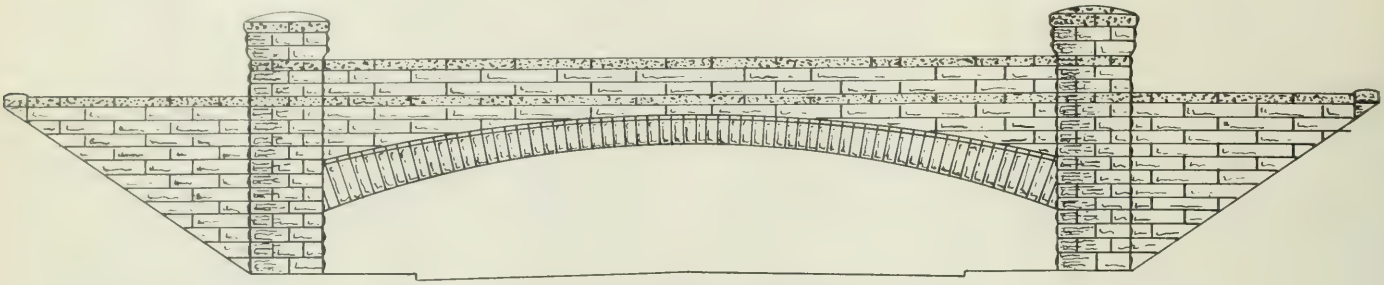

Fig. 2.—Main Street Crossing, Springfield, Mass.

Grade Elevation in Other Cities.—Various methods of grade elimination have been used in other cities, differing considerably in cost and appearance. All of these may be divided into two general classes,

(a) Those where the track is depressed,

(b) Those where the track is elevated.

The Boston and Albany Railroad through the Newtons, Mass., adopted a plan of depressing the railroad tracks and carrying the streets over on ornamental bridges. There is no doubt that this arrangement produces the most satisfactory results as far as the aesthetic effect is concerned, for the trains are then below the general level of the ground and there is no unsightly bank to obstruct the view, and divide the city into two parts. At Newton, in the vicinity of the depots, the side slopes are sodded and planted with flowering shrubs, which serve not only as ornaments in summer, but also to unite the soil and prevent the banks from sliding.

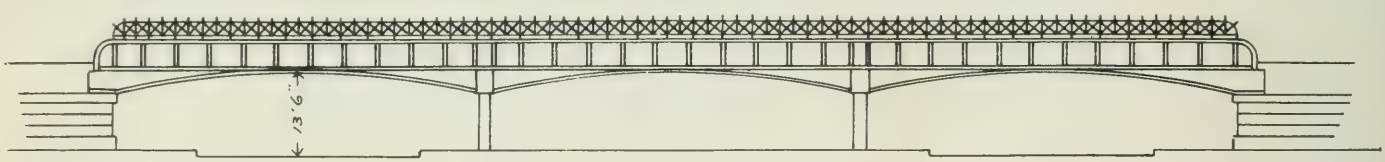

Fig. 3.—Garfield Boulevard Crossing.

Adjoining Forest Park, St. Louis, the Wabash Railroad adopted the plan of elevating the tracks on a bank of earth 15 feet in height. A view of this elevation at the main part entrance is shown in Fig. 1. The bridge over the main drive is quite a satisfactory solution of the problem as far as that feature is concerned, but the high embankment remains as a disfigurement to the otherwise beautiful surround-

ings. Such a bank forms an obstruction to the view of a beautiful park vista, that might be a permanent source of pleasure. The railroad bank may be hidden with trees or shrubs and its unsightliness concealed, but if conditions would permit, a better way would be to depress the tracks and leave a clear and unobstructed view.

The city of Springfield, Mass., has a railroad bank running across the city, but some of the street crossings have been made quite attractive, like the one shown in Figure 2.

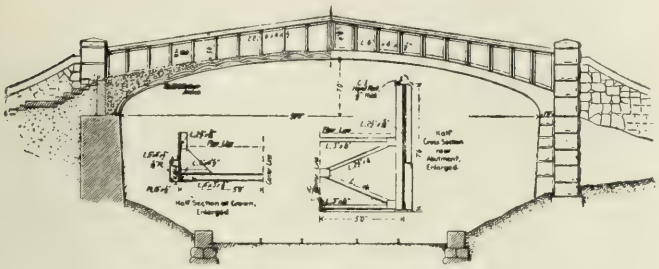

Fig. 4.—Foot Bridge, Madison, Wis.

The railroad is carried over Main Street on a stone arch, artistically designed with towers at either end and stone belt courses of different colors. The necessary head room underneath makes the use of an arch difficult in some cases, and when used, it must necessarily be a flat arch. The bridge at Springfield is so low at the springs that there is a sense of insufficient head room when walking on the sidewalk beneath the bridge. The extreme flatness of the arch also produces a feeling of insecurity and lack of strength which injures it aesthetically, for strength should, if possible, be emphasized in all bridges. Apart from the flatness of the arch, the general effect is quite satisfactory.

At Brockton, Mass., there are a number of ornamental overhead crossings, carrying lines of railroad over the

Fig. 5.—Park Bridge at Madison, N.J.

streets. These are built somewhat similar to that at Springfield, with stone arches, but at Brockton the long blank wing walls are unsightly and more prominent than the bridges themselves.

Garfield Boulevard, Chicago, is crossed by a set of railroad tracks which are supported by through plate girder bridges, shown in Figure 3. As the boulevard is quite wide, the bridge has three spans, and an effort has been made to relieve the straight overhead lines by using flat arches beneath the girders.

Other cities have treated the subject of grade crossing elimination in various ways, but generally either by track elevation or depression, as any great change in street grades is usually impracticable.

A plan used by the writer for grade elimination is shown in Figures 4 and 5. This bridge is in the park at Madison, N.J., and carries a foot walk over a double line of railway, which in this case is depressed instead of being elevated on an embankment. Similar treatment can be applied to street or highway bridges over railroad cuttings, either by lowering the railway or by grading up the street approaches instead of using steps, as in the illustration.

THE FLOW OF WATER THROUGH A POROUS MEDIUM.

By L. R. Balch.

The flow of water through a filter medium is a question of important practical application upon which our knowledge is so imperfect that a great deal of further investigating in the laboratory is required. The final object of such experimental research is to determine what factors influence the variation in results under various conditions, and what the effects of those factors are. In conducting the experimental investigations, the principal, and also the most difficult, thing is so to design the apparatus and conduct the tests that these various factors either be eliminated or be determined in effect. A large amount of work and a great deal of study is required before this can be accomplished. It often happens that, though an investigation promises to be comparatively simple, the additions and revisions found necessary as the work advances cause it to become quite complicated before satisfactory results are obtained.

Through the work done on this subject by Mr. Allan Hazen for the Massachusetts State Board of Health, and by Prof. C. S. Slichter, of the University of Wisconsin, a fair knowledge is had of the conditions influencing the flow of water through a soil column and of their effects. A number of conditions which have a very great effect on the rate of flow are quite difficult to determine, making the experimental work a matter of great care and thoroughness. The conditions which influence the rate of flow as shown by previous experiments will be taken up somewhat in detail.

The hydraulic gradient or difference in pressure from point to point, measured in the direction of flow, is the primary cause of the flow of liquid, and the greater the gradient, the greater will be the flow. The value of the hydraulic gradient is measured by means of gage tubes, similar to the piezometer tubes familiar to those acquainted with experimental hydraulics.

The porosity or amount of void space in the porous material has a great influence on the rate of flow, which varies directly with the porosity. In experimenting with a mass of spherical shot, Prof. Slichter found that a number of values for the porosity could be obtained with the same material, depending upon the arrangement or manner of packing. The minimum value was found to be 25.95 per cent. of the whole space occupied. The great effect of the porosity on the flow may be shown by a tabulation given by Prof. Slichter in Water Supply and Irrigation Paper No. 67, published by the United States Geological Survey. From this it appears that if the porosity of the same sample of sand is changed from 30 per cent. to 37 per cent., other conditions remaining the same, the flow in the latter case will be twice that in the former.

There are several methods which may ordinarily be used to determine the porosity of a sample of sand. Probably the

*From the Wisconsin Engineer.

most successful method is that used by Messrs. Cenfield and Urbutt, which is described in their thesis for the degree of Bachelor of Science in 1909. This method, by which repeated trials gave substantially the same results, is to fill the testing receptacle with thoroughly dry sand by allowing it to flow through a tube maintained at a constant height above the sand surface in the receptacle. Water is added through a pipe connected to the bottom of the apparatus from the outside. This method of filing the voids drives out the air as the water rises. A difference of two per cent. by weight was found in the amount of sand necessary to fill the apparatus in various determinations by packing the sand in any other way than by the tube method. This method has a disadvantage in that the tanks used in the flow experiments are not packed in the same way and the consequence is that the correct value for porosity to use in the computation of results is not known.

Probably the most satisfactory way would be to measure the void space in the sand when in place in the flow apparatus. This would be open to criticism, since the value obtained could not be checked, and in case the determination was incorrect, the results would be unreliable.

The larger the size of the separate pores, the greater will be the flow through the porous material. The value of this factor depends upon the "effective size" of the soil grain in the sample The flow through the interstices of an ordinary sand bed is similar to the flow through capillary tubes and is proportional to the first power of the head causing the flow. When the grains become about three millimeters or larger in diameter, the condition for free flow obtains and the flow varies in accordance with $\sqrt{2gh}$.

The method of determining the effective size will be briefly taken up in a discussion of Hazen's Formula.

The rate of flow varies directly with the temperature. This is because of the effect of temperature on the viscosity of water. An idea of the effect of change in temperature on the flow may be had from the fact that a change from 50 degrees to 60 degrees Fahrenheit will produce a change of about sixteen per cent. in the flow.

It has been found that the shape of soil particles is an influencing factor, though it is impossible to express it in the flow formulas. It is plain that sand grains that are round, flat, rough or smooth will have varying effects on the results even though the effective size is the same for each kind. Cleanliness, chemical composition and distribution of sizes in the sample also have greater or less effects upon the flow, but are exceedingly difficult to express. The distribution of sizes is shown by the "uniformity coefficient" used in selecting the value for C in Hazen's formula.

There are two accepted formulas for the flow of water through soil, one by Allen Hazen, resulting from his work at the Lawrence Experiment Station, and one by Prof. Slichter, resulting from his investigations of the flow of underground water.

The former is generally used by American engineers in their designs and has become standard. This formula is

$$V^2 = c\,d\,\frac{h}{L} - (0.70 + 0.03t)$$

V is velocity of flow in meters per day.

C is a constant depending for its value upon the shape, cleanliness, chemical composition and distribution of sizes of grain. In practice its value is assumed by comparison of the results of mechanical analysis of the given sand with those of a sand which has been tested.

d is the effective size of soil grain. It is the diameter in millimeters of a sphere whose volume is equal to the volume of that soil grain of such size that 10 per cent. of the grains in the sample are smaller. The size of grain is found by thoroughly shaking the sample through a set of sieves and finding that size which just will not pass each sieve. The results are platted and the effective size taken from the diagram. The size than which 60 per cent. of the sample is smaller divided by the effective size is termed the "uniformity coefficient," the comparative value of which is considered in selecting the proper value for C.

h is the loss of head or the head causing the flow measured between points just inside the ends of the soil column.

L is the length of sand column through which the water passes in losing the head h.

t is the temperature in degrees Centigrade. It may be noted that when t is 10° the last term of the equation becomes unity. The equivalent temperature, 50° Fahrenheit, is taken as the standard in Slichter's formula.

Prof. Slichter expressed his conclusions by the formula:—

$$Q = 0.2012\,\frac{h}{L}\,\frac{d^2\,a}{w\,k}$$

Q is the volume flow in cubic feet per minute.

$\frac{h}{L}$ is the hydraulic gradient and has the same value as is used in Hazen's formula.

d is the mean size of soil grain and is defined as that size such that if all the grains were the same, the flow would be what it actually is. This term takes care of the size of voids, the cleanliness, chemical composition, shape and distribution of sizes in the sample.

W is a number called the viscocity coefficient which depends upon the temperature for its value. It is defined as that force necessary to maintain unit difference in velocity between two strata of water unit distances apart.

K is a constant depending upon the porosity for its value. Tables of values of both K and W are given in the water supply paper previously mentioned.

Experiments which have been made show the necessity for observing certain principles in conducting investigations of the flow through sand.

Water used in the tests should be treated with some agent such as formaldehyde to prevent the growth of organic life, and should be filtered through charcoal before using. It has been found that water treated in this manner answers the purpose about as well as distilled water. The water should not be used in the tests a second time. In passing through the sand the water may dissolve material which affects its viscosity.

The temperature of the influent water should not be different than that of the effluent by more than one-half degree. In varying the temperature, the experiments should not be conducted at a temperature much above about 65° F. until a satisfactory amount of data has been taken at the lower temperatures. The reason for this is that the heated water seems to cause an entirely new arrangement of the material. The increase in temperature of runs should be made in small increments to discover the critical temperature if such exists.

SHIP-RAISING AT SARNIA.

The Steel Trust is using a novel method to raise the Joliet at Sarnia. It was found impossible for the divers to work on account of the current, so another boat will be sunk directly in front of the Joliet, which will break the current and enable the damage on the Joliet to be repaired. It is expected the scheme will be successful and the boat removed in a short time.

PROTECTING PIPE LINES AGAINST ALKALI.

The matter of the proper method of protection for pipe-lines when alkali is present is a very important one to the engineer. Many of the water supplies for our Western towns and cities must be conveyed through many miles of pipe, and adequate protection is a necessity. Mr. C. P. Bowie makes the following comment on the subject in the May issue of Western Engineering.

Most of the larger oil pools so far developed in the state of California lie in the arid districts. In the construction of pipe-lines through these districts, and leading from them to the sea-coast, one of the most serious problems the engineer has to solve is the question of an adequate protection for the pipe against alkaline soils. In the San Joaquin valley, through which the majority of these lines pass, the total alkali salts in the soils range from 0.05 up to 5 per cent., and the average composition of these salts in the soils is about as follows.

	Per cent.
Potassium sulphate	11.28
Sodium sulphate	19.48
Magnesium sulphate	2.89
Sodium chloride	23.03
Sodium carbonate	40.96
Sodium phosphate	2.08
Sodium nitrate	0.28
	100.00

In many places the percentages of chlorides and sulphates are much higher than shown. In such soils, steel pipes 5/16-inch in thickness, altho gh originally protected with three coats of asphaltum paint, have corroded so badly that pit-holes have developed, extending entirely through the pipe in three years' time. If the life of a pumping system be taken as 20 years, and the cost of the pipe installed in the system as 40 per cent. of the total first cost, it is obvious that a protective coating which will triple or even double the life of the pipe through bad territory, becomes an important factor.

Working along these lines, a number of coverings have been brought forward. Various kinds of asphaltum paint have been used, but, so far at least, without any marked degree of success. Crude oil has also been applied by covering the pipe after it has been lowered into the ditch to a depth of six inches or more with the oil, and then immediately filing in the ditch with earth. This method is only partly successful for the reason that if the soil is at all sandy the oil soaks into it, and in time almost entirely disappears from the vicinity of the pipe, leaving the metal quite as badly exposed to the alkali as before the application. Quick-setting bituminous enamels, which can be put on in a layer ⅛ to ¼-inch thick, bid fair to give results. However, up to the present, these have one serious drawback, in that they cannot be successfully applied to a moist pipe or to a pipe having a lower temperature than 60°F., because the enamel, although it is put on at a temperature of approximately 200°F., is chilled so rapidly that it hardens before it can be spread. The action of the mop with which it is applied is merely to roll it into a myriad of balls or globules which do not stick to the pipe at all but fall to the ground. This not only causes a great waste of material, but is apt to leave many small portions of the pipe, especially on the under side, wholly unprotected even though several coats of enamel are put on. This difficulty can be largely overcome by applying the enamel in warm dry weather only, or to pipes through which warm oil is being pumped. There are no lines in this state which have been covered by this process and allowed to remain in the ground for any great length of time. One line passing through slightly alkaline territory, which was covered in this manner about two years ago, was found to be in excellent condition upon a recent examination.

The method of covering most extensively used, and perhaps the most successful one, is that employing especially prepared roofing papers. The papers commonly used are those made from ordinary deadening felt run through a mill in which the felt is plunged into a number of successive baths of hot asphaltum and rolled hot and under pressure after each successive bath until the fibres of the paper are thoroughly impregnated with the asphaltum. Just before entering the last set of rolls the paper is sprinkled with either mica or soapstone, which mineral, while it no doubt adds somewhat to resistance against the attack of chemicals, has for its principal function the quality of affording a means of keeping the paper from sticking in the roll in hot weather Asbestos papers, prepared somewhat in a similar manner to the felt papers, have also been used in a number of places.

These papers are applied to the pipe by two methods, known locally as the "spiral warp" and "longitudinal lap." The spiral warp, which is in most cases the most efficient method, consists of applying the paper to the joints between collars by wrapping it around the pipe spirally. For this purpose, the paper is cut in the mill into rolls of the desired size, varying from 3 to 12 inches in width, and containing from 50 to 100 ft. in length as best suits the diameter of pipe to be covered. The pipe is covered immediately after being screwed together by the tong gang, and while still on skids over the ditch. It is coated with hot asphaltum and the wider strips wound on spirally before the asphaltum has had time to set. The crack which is left between each wrap of the wide strip is then coated with the hot asphaltum, and a batten, or 3-in. strip, wound on to cover it. The asphaltum used is a thin grade of the ordinary refined product, and is applied to the pipe at a temperature of about 200° F., and is of such a consistence that it will not set for about five minutes after application. If, due to climatic conditions or variance in the different shipments, the asphaltum sets too quickly, a so-called flux, which is simply a very thin grade of asphaltum, is added. It is usually the practice to ship one barrel of "flux" to the field for every 60 barrels of asphaltum. At the joints 3-in. strips stuck together with asphaltum are wound around the pipe on either side of the collar until a shoulder is built up flush with the outer circumference of the collar. The sleeve and shoulder thus built up are then coated with hot asphaltum, and the whole covered with a 12-in. strip of paper. Besides being stuck to the pipe with asphaltum, this last strip is bound on with wire, as are also the ends of the paper where it is wrapped spirally. If this is not done, the ends will curl up and allow dirt to get between the paper and the pipe after the pipe has been lowered into the ditch, and before the back-filling has been done.

The longitudinal lap system, which to the present time has been much more extensively used than the system just described, consists (as the name implies) of wrapping the paper longitudinally around the pipe. The paper is delivered in the field rolls, about 6 in. wider than the circumference of the pipe to be covered, each roll containing approximately 72 lineal feet. Two men go ahead of the paper gang and measure up each joint of pipe between collars and cut the paper into the desired lengths.

In applying the paper to the pipe, undoubtedly the best method is first to coat the pipe with hot asphaltum as previously described; then to wrap the sheet of paper around the pipe and stick down the lap with hot asphaltum. This, however, is not often done when covering lines where the oil passing through is to be heated, the supposition being that

the heat of the oil (usually about 130° F.) combined with the pressure of the earth on the pipe after it has been buried will be sufficient to soften whatever asphaltum there is in the paper and form the necessary bond between paper and pipe to keep the water out. Without question, this supposition is correct to a certain extent. The paper, especially where a heavy quality is used, will undoubtedly adhere to the pipe in most places where it comes in contact with the metal; but it is to be noted that roofing papers applied to a pipe, while still on skids above the ditch, and allowed to stand in the sun for a few hours, will stretch to such an extent that the contact will be found to be on the upper circumference only, there being often as much as one-quarter of an inch of space between the bottom of the pipe and the paper. It is a serious question if this same thing does not occur when the heat from the oil first reaches the paper, even though the pipe has been lowered into the ditch and covered up. The paper, of course, does not bag uniformly as in the case above ground, but the surplus is taken up in wrinkles, and these wrinkles are very apt to be connected for the entire length of a joint of pipe. Should any injury occur to one of these wrinkles, or a crack develop in it, which will undoubtedly be the case as oxidation goes on, it is not at all improbable that water, which would enter, would reach every place in a joint of pipe where the paper was not securely stuck on, and thus render the whole covering practically useless. Where asphaltum is used as a binder, the wrinkles that form will be filled, thus preventing the water from entering, even though the paper should in time crack at these points. Time alone, however, can solve this much-mooted question, since there are no lines in California protected in this manner that have been laid a sufficient length of time for these cracks to develop.

For covering the collars, the same method is used as with the spiral wrap, except that the binder is often omitted. This it would seem, is even more serious than omitting the binder from the main body of the pipe, since it gives the water a chance to get between the paper and pipe through the ends of the wrinkles.

Whether a binder is used or not, the lap should always be made on the top of the pipe with the outer portion of the lap looking down, and wires should be placed about every sixteen inches. This is necessary to prevent the paper from being pulled away from the pipe by its own weight before it can be lowered into the ditch and covered.

RATS AND PLAGUE.

The bacteriological examination of 100 rats, at the public health laboratory, of Manchester, England, which was commenced during the previous year, was completed in June last. No bacilli suggesting plague were discovered in any of the bodies, but in six cases parasitic cysts of the liver were found; in only one case were bacilli of a possibly pathogenic nature seen, but of course not plague producing; in nineteen cases putrefactive bacilli or cocci were discovered; in twenty-three trypanosomes were found in the blood. The last mentioned feature, although having no special indication so far as is known at the present time, is somewhat interesting. Trypanosomes are a species of protozoa or low form of unicellular animal parasite of a flagellate or whip-like shape which infest the blood of man and animals, and which are responsible for various diseases in reptiles, mammals, fishes, etc. One variety (trypanosomes gambiensis) produces sleeping sickness, and is introduced into the blood of human beings by means of a fly. Knowing the way these parasites are carried from one body to another, it is certainly interesting, if nothing else, to find so many of the rats thus infected.

NEW METHOD OF PURIFYING WATER.

What is understood to be a new method for the speedier purification of Thames water has been discovered by Dr. A. C. Houston, of the Metropolitan Water Board. He adds lime to raw water in such quantity as to kill all the germs. He states that when 1 part of quicklime (about 75 per cent. CaO) is added to 5,000 parts of raw Thames water, about .007 per cent. free CaO is left in the mixture, and this excess is sufficient to kill B. coli in from five to twenty-four hours. The result of this process is to make the water unusable on account of the quantity of lime in it, and Dr. Houston proposes to correct this by mixing it with natural water which has been purified by storage. It would require about one part natural water for three parts quicklime water to produce a potable mixture. Thus it would be sufficient to purify only a third of the water needed for London by storage. The rest could be dealt with by lime and then mixed. The principle is thus described by Dr. Houston:—

Fifteen lbs. of quicklime, costing three-halfpence, would be added to 7,500 gallons of raw unstored Thames water. This would kill within twenty-four hours the B. coli, and inferentially, but certainly, the microbes also of epidemic water-borne disease (e.g., the typhoid bacillus). The water would also be improved considerably, as judged by physical and chemical standards. The excess of lime (about .007 per cent.) would then have to be neutralized with 2,500 gallons of adequately stored water, which, according to all my experiments, would not contain any of the microbes of epidemic water-borne disease. Thus 75 per cent. of the water would be sterilized chemically, and the remaining 25 per cent. by nature's own method of sterilization (storage). The mixture would have lost about 75 per cent. of its total hardness, and would contain no undesirable excess of free lime, besides being perfectly innocuous. Rapid filtration alone would then be required to remove the precipitate of inert carbonate of lime, and to bring the water up to a reasonable standard of chemical purity.

The system would be more expensive—in fact, doubly so—than sand filtration, but it would have certain distinct advantages, notably, its adaptability, its special suitability for flood waters, the saving in soap, the capacity to render quickly an initially foul water absolutely safe, the postponement of the construction of new storage reservoirs, and the raising of the purity of the metropolitan water supply to a pitch of perfection never before attained.

TUNNEL UNDER COLORADO RIVER.

The task of boring a tunnel under the Colorado River has been accomplished. Reports received by the United States Reclamation Service announce that the top drift of the Yuma tunnel penetrated the California bank on May 3rd, making connection with the shaft on that side, and completing the crossing of the stream. This tunnel, or siphon, is one of the most dangerous and difficult engineering structures undertaken by the Reclamation Service. It is one of the features of the Yuma irrigation project, which will reclaim 100,000 acres of the arid lands in the delta of the Colorado, known as the American Nile. It will carry water from the main canal on the California side to the Arizona canal system.

The great siphon will be 1,000 feet long, with an internal diameter of fifteen feet. It crosses the turbulent Colorado River 100 feet below the surface of the stream, and penetrates for the entire distance a soft and pervious sandstone formation. Its construction required the use of compressed air methods similar to those employed on the Hudson River tubes.

THE LITTLE SALMON RIVER VIADUCT. NATIONAL TRANSCONTINENTAL RAILWAY.

In recent issues of *The Canadian Engineer* there was described the new Red River bridge for the National Transcontinental Railway. This bridge includes a bascule span

Fig. 1.—General View of Viaduct.

and is a most interesting structure. The Little Salmon River viaduct for the National Transcontinental affords another interesting example of bridge work on the new railway. Mr. R. F. Uniacke, the bridge engineer for the Transcontinental, has described the structure very fully in a paper before the Canadian Society of Civil Engineers. An abstract of the description is given below:

The Act of Parliament, authorizing the construction of the eastern division of the National Transcontinental Railway, provides for a location from its eastern terminus (Moncton) through the central part of the province of New

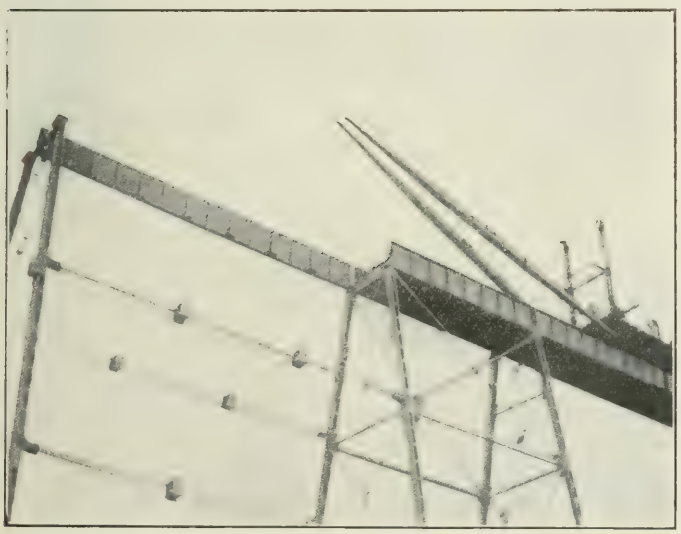

Fig. 2.—100-Foot Girder in Place.

Brunswick, and through the province of Quebec by the shortest available route to the city of Quebec.

The engineers of the Transcontinental Railway had located two lines, one known as the River route, following the St. John River, north from Fredericton, and the other the Central route; the latter was adopted as fulfilling more closely the provisions of the Act. That a line of railway has now been constructed along this route having a ruling point four compensated grade, with a maximum curvature of six degrees, is owing in a large measure to the advance in modern bridge and high viaduct construction. The valley of the Little Salmon River, 185 miles from Moncton, presented one of the obstacles to be overcome, as the grade development showed a crossing over 4,000 feet long, with a height of 200 feet above the water line.

The line approaches the west end of the structure with a six degree curve through a rock cutting and crosses on a tangent bearing N. 10°—27 ft. W., the grade rising 0.40 ft. per hundred. The layout consists of twenty-four towers 58 ft. 9 in. centres and twenty-five intermediate spans 100 ft. 3 in. c. to c., the end spans being 100 ft. 10½ in. centre of bent to outer end of steel; all the tower spans are alike and also the intermediate spans, except that the masonry ends are extended to give the required bearing. The towers and bracing are made alike as much as possible,

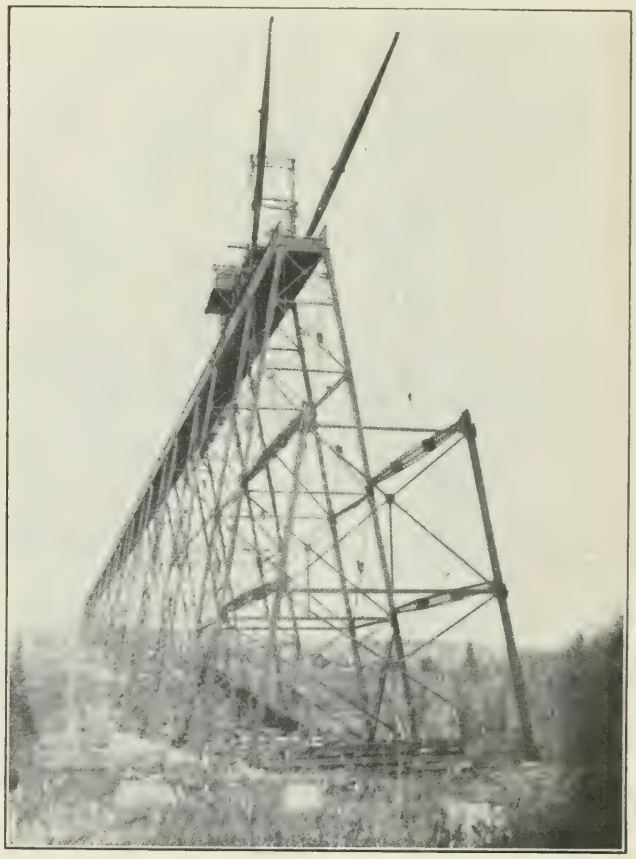

Fig. 3.—View of Erection.

necessitating one set of templates only for the spans and parts of towers which duplicate each other. A through girder system of construction was adopted, the girders being spaced 17 ft. 6 in. c. to c., while the floor beams with gussets were spaced 14 ft. c. to c., along the plate girders. The east end span is on a spiral to a 6 deg curve and in consequence the girders are deflected at this abutment 1 ft. 3 in. off the tangent to the structure produced. There were several reasons which led to the adoption of a through girder system. In high trestle construction where the use of falsework is out of the question, the most economical layout is that on an intermediate span as long as could be handled with a well designed traveller working from grade, so as to reduce the number of high towers, their pedestals and foundations. Spans of 60 ft. with 40 ft. towers are generally employed where deck girders are used, spaced 9 ft. c. to c., and bridge ties resting on the top flanges. Owing to the through girder system having a spacing of girders 17 ft. 6 in. c. to c., spans of 100 ft. are handled, since the bear-

ings of the traveller rest on the flanges, thus giving that much more base to brace the traveller in handling loads. The stability of the erection outfit is amply provided for so that in this case girders weighing 30 tons were placed in position. It certainly gives a feeling of safety to see from the car window the flanges of a heavy steel girder, and that this is not altogether sentiment is shown by the fact that instances of derailment are recorded, in which the car held to the roadway by the lateral resisting power of these girders.

The approach at the east end being through a rock cutting, in order to avoid building the steel work on a curve, and also to utilize the material in the cutting without waste, an abutment of reinforced concrete placed on top of the rock fill was decided on. A buried pier built from the original line at the banks of the river were built with curved cutwaters, the axis of piers being parallel to the direction of the current, forming suitable icebreakers. The anchor bolts for pedestals consisted of two rods, two inches in diameter, the lengths varying according to the up-lift to be resisted. These rods were anchored at the bottom by spacers of 10-in. channels and washers, the concrete being built around them. In order to give room for a little variation in their position, conical forms were set around each bolt, a lip being left at the top extending beyond the base plate of column through which these voids were filled with grout after the steel was erected. The west abutment or buried pier was about 40 ft. in height above the footing course, and in order to reduce the pressure on the soil and allow the embankment to run through and surround it, an arched void was left in a

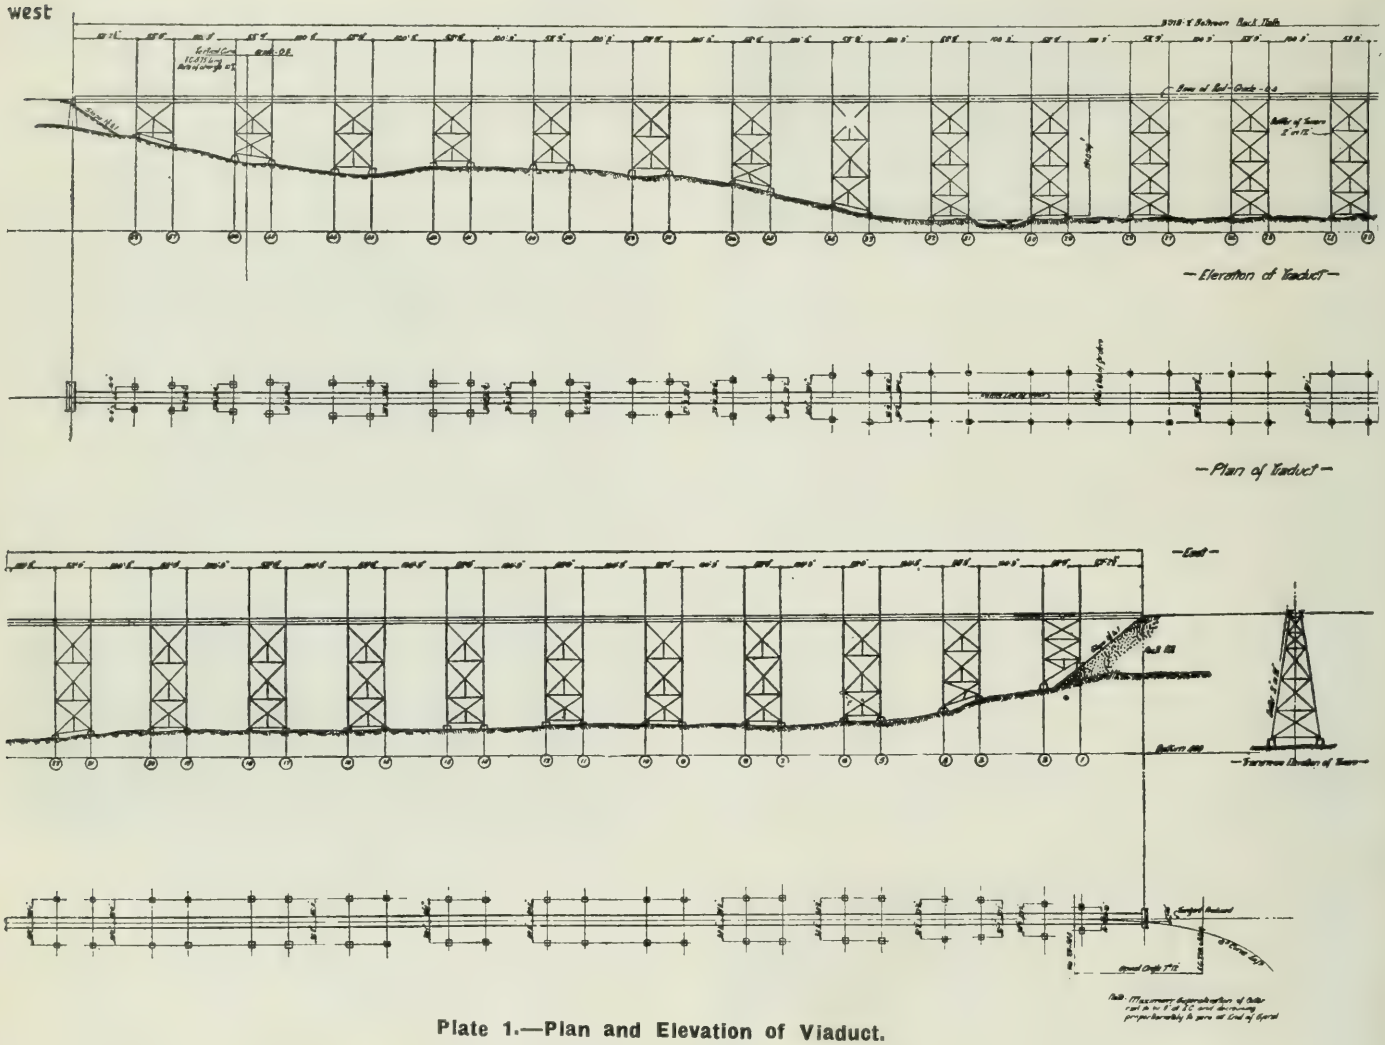

Plate 1.—Plan and Elevation of Viaduct.

surface at this point would have been over 100 ft. high, difficult to design and build, and very costly. This was avoided by the use of a bank abutment. The concrete was reinforced to prevent danger of cracks from settlement in the bank, and in order to give time for the bank to settle, the ends of the girders were temporarily supported by a cribwork of square timber, before building the permanent abutment.

In the design of the pedestals and west abutment, borings and test pits were first made to determine the character of the soil. This proved to be of compact sand, gravel and hard pan, so that no piling was required, the footings being designed to distribute the load at a pressure of from 2.5 to 4 tons per square foot. The four pedestals near the water

longitudinal direction. No difficulty was experienced in building to this design.

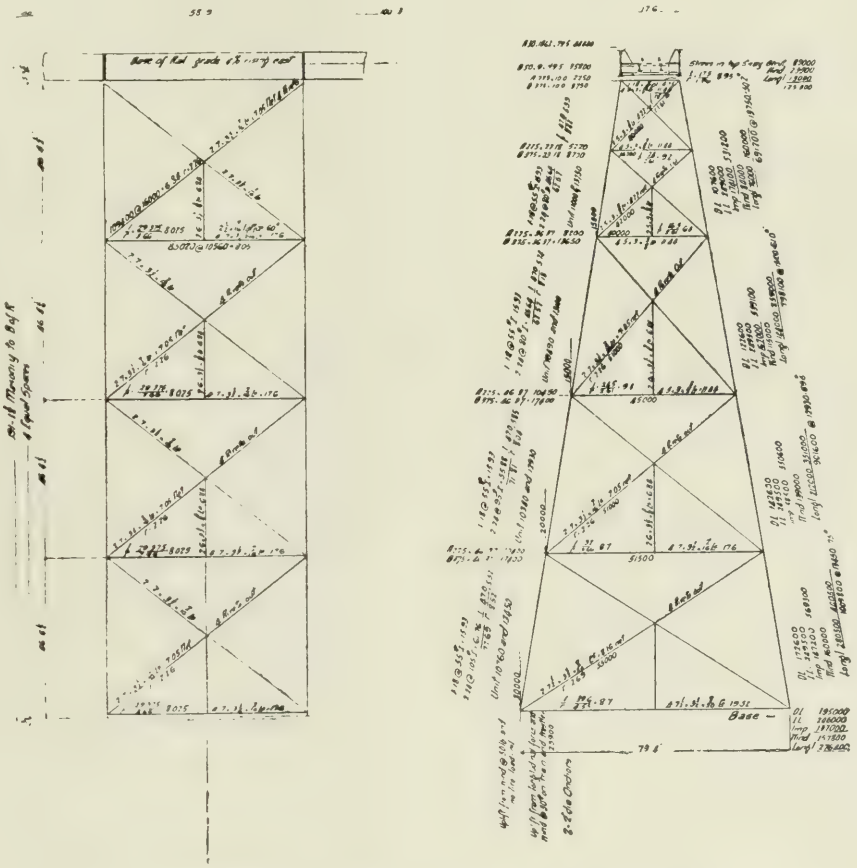
In laying out the work no triangulation was required and an ordinary steel tape was used, the writer's experience being that, as provision is made in the girders for expansion, a slight variation in the position of the anchor bolts is permissible, providing the expansion slots are made longer than the theoretical length requires. The chief difficulty consists in maintaining the anchors in a vertical position and protecting them from rough usage from swinging buckets of concrete and other causes.

The materials used in the concrete were international Portland cement, manufactured in Hull, Que., at present by the Canada Cement Company. The sand and gravel were

obtained on the bank of the river near the bridge site. In this locality good sand is very difficult to obtain, and, after a test of sand from several pits, the local material was selected, the sieve test showing after the gravel was screened out:—

Retained on	20	mesh	sieve	.....	64	per	cent.
" "	30	"	"	.....	17	"	"
" "	50	"	"	.....	15	"	"
" "	74	"	"	.....	2	"	"
" "	100	"	"	.....	2	"	"
					100%		

After treating the finer residue with a 20% solution of sulphuric acid, it was found to contain 6% of soluble matter, which was eliminated by thorough washing, and a mixture of one part cement, two parts sand, and four parts gravel, varying from the size of a pea to three inches was obtained. As the sand was not of the best quality, the use of 1:2:4 mixture was ordered in shafts of pedestals, since they have to sustain a high concentrated load on a comparatively small volume of concrete. The concrete used in the buried pier and foundations was a 1:3:5 mixture. In obtaining a proper facing mixture the coarser material was kept away from the forms by the use of perforated spades, pushed down and drawn back while the mixture was still plastic. This method was found more satisfactory than that of attempting to bond a facing mixture into the body as required in some specifications.



A Typical Bent on the Little Salmon River Viaduct.

The Dominion Government specifications were strictly adhered to in the proportioning of the members. The compression members were figured for the pin ended formula of these specifications. In the tension members of the towers a limiting length $\frac{l}{r}$ of 200 — was used to avoid sagging of members, to make them capable of resisting compression and to give initial stiffness. Attention is called to the use of bulb angles in the sway bracing of towers, which make a very stiff and economical section and avoid breakages in shipment. the great fault in box laced section of light angles. Traction and wind were figures as called for in the specifications.

The posts viewed from the stress sheets do not appear to be economical because of their relatively small radius of gyration when compared with a built up channel section; but the saving in weight of details and simplicity in shop work fully compensates for the extra main material. In the light of column tests it is reasonable to expect that the reduction in unit stresses for the increase of radii length would not be justified by practical tests. The metal is used mostly in directly resisting the primary stresses, as very little is required for secondary purposes (viz., lattice tie plates, etc.), and in this way a stronger column is obtained. The section used has also the advantage of continuous webs in each direction, which are greatly superior to the easily bent lattice bars, and moreover the interior of the column is much more accessible to the paint brush for shop and field coats. The section is symmetrical on both axes. having therefore its centre of gravity in the centre of the section, and no eccentric loading is induced from the girders. The small amount of redundant metal means uniformity of stress in the columns, and simplicity in the make up will decrease the cost of maintenance.

In calling for tenders for the steel work our usual practice was followed of furnishing bridge companies with a general design and details of girders and towers, together with a printed form of tender in which was filled in the estimated weights of steel, and number of feet B.M. of timber in the floor. With this system all bridge companies bid on the same basis, and are not required to make a single drawing to submit with tenders, but merely to fill in the unit prices for steel and timber erected in place, and to carry out the amounts on the estimated quantities furnished, viz., steel 14,000,000 lbs., timber 520,300 ft. B.M. After the tender is awarded the bridge company submit stress sheets and details for approval before ordering the material from the mills.

The rails were directly supported by 8-in. by 12-in. by 14-ft. bridge ties resting on the steel stringers, every fourth tie being 16 ft. long to support the plank footway placed outside the guard timber for the convenience and safety of the section men. An outside guard timber 8-in. by 9-in. dapped 1 in. over the ties, which were spaced four inches apart in the clear, the ties were secured to the stringers by ¾-in. hook bolts, and the guard timbers bolted through the tie with one ¾-in. bolt in every fourth tie. A steel guard rail 60 lbs to the yard will be placed inside the gauge line and eight inches therefrom in the clear, these guard rails coming together at the centre of the track one rail length beyond the end of the bridge and being protected by a cast steel point fitting the rail section and spiked to the road-bed ties.

Actual erection began July 27th, 1910; the steel was all assembled and last span swung February 8th, 1911, and all riveting and painting fully completed by August 19th, 1911.

The erection staff varied from 60 to 80 men, of which but six were employed on the big traveller, one sub-foreman and 14 men were used to assemble the steel work, and the rest formed from two to six gangs of riveters, also crew for derrick car used for unloading material in yard, and delivering same to traveller, and driver for light locomotive. The riveting gangs averaged 302 rivets per day of 10 hours per gang, a rate which would probably have been reduced by 50 per cent. if ordinary staging had been used, instead of the riveting cages.

One coat of Sherwin-Williams Black Metalastic paint was used in the shop, with a coat on each contact surface before assembling. Two field coats were applied, the first Metalastic brown, and the final coat Acheson Graphite. Rivet heads and shop marks were touched up before applying the field coats. The use of a different shade for the first field coat was a great help to the inspector, to enable him to see that the several coverings were properly applied.

In the final estimates the actual amounts and cost under the several items are:—

Substructure.

1,757	cu. yds.	1:2:4 concrete	@	$15.00
6,524	"	1:3:5 "	@	11.00
4,597	"	Excavation	@	1.00
10,534	"	"	@	2.50

Superstructure.

Steel	13,991,310 lbs	@ 4.68 cts. =	$654,793.31
Timber	518,041 ft. B.M.	@ 4.60 cts. =	23,829.89
			$678,623.20

Progress estimates were paid monthly on the superstructure according to the following basis:—

	Unit.	Rate.
Steel	100 lbs.	$ 4.68
Timber in floor	M.B.M.	46.00

Schedule for Monthly Estimates.

	Unit.	Rate.
Steel provided	100 lbs.	$ 2.00
manufactured	"	1.00
delivered at site	"	.40
assembled	"	.98
riveted	"	.15
painted and fully completed	"	.15
		$ 4.68
Timber delivered	M.B.M.	$40.00
framed and placed	"	6.00
		$46.00

The basis of payment was considered a fair and equitable distribution of cost throughout the different stages of manufacture. It is the result of experience on many bridges previously built by this and other bridge companies on the described method of working and specifications, and the writer believes may fairly be used in other similar cases, as proportionate cost data.

The work was carried out under the general direction of the writer from the bridge engineer's office in Ottawa, Mr. W. A. Duff, assistant bridge engineer, having charge of the general design and details. The Dominion Bridge Co., Limited, Montreal, were the contractors for the steel, which was efficiently carried out, Mr. F. P. Shearwood, C.E., having charge of the design for the bridge company.

The design and layout for the erection and the traveller were made under the direction of Mr. James Finley, superintendent of erection, who was responsible for the successful carrying out of the erection; also Mr. E. W. Nichols, foreman on erection.

The mill, shop, and erection inspection was satisfactorily carried out by the Canadian Inspection Company, Limited, Montreal.

The sub-structure was completed by Messrs. Powers & Brewer, sub-contractors under Willard Kitchen Co. The construction and laying out of this part of the work was performed under the direction of Mr. C. O. Foss, district engineer. Although the work was prosecuted in all seasons of the year there has been no accident or casuality of any kind.

A NEW PEAT MACHINE.

In the January issue of the Journal of the American Peat Society is a description of a peat digging machine which is in operation at Elizabethfehn in Oldenburg, Germany, designed by Dr. W. Wielandt.

Dr. W. Wielandt has designed a peat digging machine which is absolutely automatic in its working, so that much less hand work is required than formerly, and by its use the production of peat fuel has been reduced to a half or a third of its previous cost.

This machine, which is protected in the United States by Patent No. 996,898, and in Canada by No. 126,536, consists of a uniformly forward-moving truck or car operated on a portable tramway of 600 mm. (23.6 inches) gauge; from the side of the car is suspended a chain and bucket dredge 3 to 5 meters (10 to 16.5 feet) long and about 1 meter (3.28 feet) wide. On the same car is mounted a double-screw macerating machine, to which the raw peat is fed through a hopper that receives the peat as it falls from the buckets of the excavator. The macerating machine is provided with a mouthpiece of pentagonal cross section, and an automatic cutter which cuts the peat into bricks of uniform length as it is forced from the outlet. Coupled to the frame of the machine and moving forward simultaneously with it, is a belt conveyor which receives the bricks as they are cut off from the peat strand issuing from the mouthpiece. The conveyor automatically drops or lays out the peat bricks upon the whole width of the drying field as soon as the band reaches the end of its travel. The drying field may be from 12 to 30 meters (about 40 to 100 feet) in width.

The machine can be modified in its details to suit the conditions of the bog on which it is to be operated. It can be operated by an electric motor or by a gasoline engine, which may be placed on the car or on a special, independent truck, so as to be usable as a locomotive to draw the dry finished fuel from the drying field to storage sheds.

The standard machines will produce from 6 to 7 tons of air-dried peat bricks an hour, equivalent to about 40 or 50 cubic meters (52.3 to 65.4 cu. yds.) of raw material. The power required to operate the machinery is 20 horsepower. The cost in Germany for this type of machine, including the cutting device and brick conveyor, is from M. 12,000 to M. 14,000 ($2,400 to $2,800), which with duty of 47 per cent. and freight charges would make the cost, delivered in New York, from $5,000 to $5,200.

During 1911, three of these machines were in operation at Elizabethfenn, Oldenburg, the oldest one having been used for three summers, and, in the opinion of peat engineers who have tested them, they have shown the highest efficiency and economy.

The machine, when compared with others, has the following advantages: (1) Every individual process is absolutely automatic, so that only 2 or 3 workmen are required, as compared with 12 to 15 needed by older types of machines. (2) All movements of the machinery are continuous and uniform, hence its construction is simple and it is easy to operate. The utilization of the power is also uniform and in this way the wear and tear is reduced to a minimum.

(3) As the dredging covers only the width of one meter (3 ft. 3.4 inches), only the drier material on the face of the cuts is worked. This drier material, as shown by experience, contains about 12 to 15 per cent. of dry substance, as compared with but 5 to 10 per cent. contained in the underlying material. In other words, the peat obtained in this way contains materially less water when dug and macerated, and dries faster afterwards, than that produced by the

Peat Machine in Operation, Rear View.

old style machines. These facts make possible more frequent use of the drying field and also a more extended drying campaign.

(4) The light weight of the machine, about 2,500 kilogrammes (5,500 pounds) and the production of a sloping cut or bank, instead of a perpendicular one, permits the working of either fresh, undrained bogs, or of those which have been cut up by cracks caused by too rapid drainage. As there is no necessity for supporting the outer dredging boom, it is possible to dig the lower layers of peat from below the surface of the water.

(5) The dredging boom can be lowered or raised while the work is going on, without stopping the machine. The boom has a wide range of movement, which makes it fit to any slope of cut and depth of opening desired. In other words, the machine can be adjusted to any bog condition desirable and can be made to avoid any obstructions in the cuts, such as sand hills or tree stumps, without loss of time. If it is desired to remove the machine from one ditch to the other, it is only necessary to raise the dredging rig and swing it parallel to the long axis of the machine, when it is out of the way. This arrangement makes it possible also to move the machine easily on any track, turntable, switch, etc., of a portable tramway, without dismantling the machine or any part of it; therefore, the time required for such changes is reduced to a minimum.

(6) The machine proper, together with the brick conveyor, can be moved for considerable distances without difficulty, as it travels on a standard gauge 600 millimeter portable track.

(7) The deposition of the peat bricks on the drying field in a horizontal position, and their pentagonal form, favors the free run-off of any rain water which may fall on them and this lengthens the campaign about 50 per cent., or from 6 to 8 weeks, because the water does not soak into them. The three of these machines at work in Elizabethfehn during 1911, were operated during September, under such conditions. Peat machines of all other makes in that part of Germany were closed down at the end of July. From 25 to 30 per cent. more production, in effect, is gained by its use, from the fact that the time needed for moving and swinging this machine is reduced to a minimum, whereas, by the old systems, out of a possible 100 working days, only 60 to 70 could be utilized, as the rest were taken up in moving the machinery.

(8) The machine can be worked day and night, with electric light, so that the daily number of working hours can be increased to 20 instead of being limited to 10 or 12, as manual labor is practically excluded.

(9) As the buckets of the dredge work all depths of the bog simultaneously, a thorough mixing of the raw material is obtained and the result is a more uniform and even-textured product than that made by other styles of machines.

The cost of operation is as follows: A production of 6 tons of dry peat an hour, 15 hours a day, for 100 consecutive working days, is assumed; $6 \times 15 \times 100 = 9{,}000$ tons of air-dried peat for each machine for a working season. Three workmen to each machine at 8 marks ($1.60) a day each = 24 marks

	Marks.	Cents.
($4.80), or for a ton of air-dried fuel.....	0.26	5.2
Power required, 15 to 18 h.p. or daily about 200 kilowatt hours = 22 marks, or ($4.40) amounting for each ton of air-dried peat	0.24	4.8
Drying the bricks on a large scale, per ton, about	0.70	14.0
Materials and repairs, about.....	0.20	4.0
Supervision	0.20	4.0
Transportation of raw material for each 3 or 4 k.m.	0.40	8.0
Depreciation of 20 per cent. on machine and track	0.50	10.0
	2.24	44.8

or under 2.50 marks (50 cents) per ton of air-dried peat at the factory. This amount can be reduced if work is done day and night.

REFORESTING IN HASTINGS COUNTY.

As a result of the Act passed by the Ontario Government last year empowering municipalities to engage in forestry, the county of Hastings has already taken steps to acquire waste lands for the purpose of reforesting them. During the coming summer the Dominion Commission of Conservation will supervise a survey of the county of Haliburton and the northern portion of the county of Peterborough. This survey is to furnish a detailed description of economic and natural conditions and resources of the watershed in Peterborough and Haliburton counties feeding the Trent Canal waters and to serve as a basis for a system of management.

AN ENGINEER'S FINANCIAL RETURNS.

There is no good reason, says Mr. Chas. T. Main, president of the Boston Society of Civil Engineers, in a paper read before that body, why an engineer should not be as well paid as a lawyer or doctor. Mr. Main says:

A fellow-engineer said one day: "The hardest thing which I have to do is to make out a bill for services." It is here again that the natural modesty of the man is such that he is unable to appreciate the worth of his own services.

Some of us are called upon to make investigations and reports on enterprises involving the expenditure of millions of dollars, and the conclusion reached and the signature at the end of the report may prevent our clients from losing large amounts, or may cause them to embark in an enterprise which will net them great profits.

The concentrated knowledge and experience of years may be given in a short period, and yet we are apt to measure the value of our services on a per-diem basis, which will amount to a pitiable sum compared with the importance of the service rendered. This condition should be remedied so that the returns will be commensurate with the value of the services rendered. A lawyer of high standing, in making his charges, would consider not only the time required but the importance of the case or value of services rendered.

There is no good reason, aside from custom, why the engineer should not be as well recompensed for his services as is the doctor or the lawyer. The engineer engaged in the industrial development furnishes his services, as a rule, to a clientele that can afford to pay the full value for services rendered. Where a problem has been carefully studied, and the work carried out in accordance with the final conclusions, the result enables a saving in cost of production or an increase in profits. The engineer who works along these lines is carrying on the work of efficiency of which so much has been said and written recently. The industries can well afford to pay the cost of obtaining the benefits derived from good engineering.

In the regular pursuit of design and construction, there seems to be no way of charging more than some definite fixed sum or percentage, the aggregate of which cannot be large unless the undertaking is unusually large.

Many of our profession hold salaried offices, and the salaries are not very large as a rule; but the tendency of later years has been to make a better return for services rendered.

To the younger members the progress seems to be slow, but with ability and willingness to work there is no reason why success should not follow. Some of the greatest engineers have been men who have not had the advantages of technical training and have forged their way to the front by close application and native ability.

The young graduate from a technical school is apt to think he knows it all; and if he is well balancel he will soon find that he has laid a good and substantial foundation during his studies on which to build his education for effective work which will be of value to his employer, and which will develop from day to day in the actual performance of his work. If he is well grounded in the fundamental principles of the profession he will be able to undertake and carry out any work which is assigned to him; but he should have patience, and not expect too rapid advancement in position and salary.

For these reasons the younger men should be modest in their expectations and consider a part of their remuneration the valuable experience which they are acquiring.

After an engineer has had many years of experience and hard work, and his work and judgment are of great value to his clients, he should rise above his modesty and charge a sum commensurate with the value of his services. At the present time, however, it does not seem as if a large percentage of the profession could derive more than a good living from strictly professional work.

Some time ago one of my clients, who is very successful in manufacturing, said that his son thought he would like to be an engineer, and the father desired some advice as to the best thing for a boy to do. I told him that if he wanted the boy to make a lot of money, he should take him into business with him, but if he wanted him to have an honorable profession which would probably procure a living for him, but not much margin, to make an engineer of him.

FLAT SLAB BRIDGES.

By W. H. Finley, Asst. Chief Engineer Chicago and Northwestern Railway.

Since the introduction of concrete for the construction of railroad bridges no type of structure has met with more success than the flat slab bridge. In the days of stone masonry we were confined to the flat top culvert for openings up to four or five foot spans. Beyond that it was necessary to use the arch type. This meant increased expense in construction due to the cost of the cutting of the masonry for the arches. For years after the introduction of concrete it was a common practice to use, for small openings, say up to eight or nine feet, old railroad rails embedded in the concrete to form the top covering. In those days there was more or less second hand rail that could be used economically for this purpose and it was thought that in using the material in this way a cheap and satisfactory structure could be produced. It was soon discovered, however, that second-hand rails were not always available, and if available they could be put to better use than burying them in concrete for culvert construction. In spans greater than nine feet and up to thirty feet it was the practice, for a number of years, to use I Beams embedded in concrete. Among some engineers the idea to use beams of sufficient strength to carry the live load and consider the concrete only as taking the place of lateral bracing. This form of construction required very careful work in the field, inasmuch as it is difficult to make a satisfactory bond between concrete and large areas of metal, as represented by an I Beam, and with the greatest care in the selection of the material and the placing of the concrete it was difficult to prevent the same from cracking or separating from the beams. Although there were a number of satisfactory bridges built of this type, yet it was gradually abandoned. As confidence grew in reinforced concrete these smaller openings were built of the reinforced flat slab type. This type not only took the place of stone arches of corresponding span but also at a much less price. It enabled engineers to satisfactorily solve a great many problems in places where a wide and low opening was particularly desirable. The ideal structure from a railroad standpoint of use is that type that entails the least cost in maintenance. Stone masonry, however carefully constructed, required from time to time repointing to prevent the infiltration of water and consequent disintegration of the structure. With concrete properly constructed this maintenance charge is completely eliminated. Not only is the maintenance charge eliminated but the first cost of construction is considerably reduced. In the building of a flat slab bridge as a monolith it is possible to use less material in the side walls than would be required for an arch of corresponding span.

*Presented at the Eighth Annual Convention of the National Association of Cement Users, Philadelphia, Pa.

In railroad construction numerous instances occur where it is necessary to provide a wide and low opening and this condition is admirably met by the flat slab type of bridge. Before the introduction of this type of construction it would be necessary to provide an arch that would entail very much more expense than the flat slab bridge. Of recent years the flat slab bridge has been used to good advantage in cities where railroads were eliminating grade crossings by the elevation of their tracks. In the ordinary 66 ft. street where the city permits supports in the centre of the street and on the curb lines it is possible to use the flat slab type of bridge for spanning these openings. This results in a very economical form of construction as well as one that can be made aesthetically pleasing in general appearance. It also reduces to a minimum any maintenance expense. A steel structure for a similar opening requires painting every four or five years and if this work is not attended to the structure soon presents an unsightly appearance. This condition is very prominent in our elevated railroads in cities where the maintenance is not kept up.

Twenty years ago, in railroad construction, it was the universal practice to use, in openings from six to thirty feet, open deck I Beams. These were usually placed upon concrete or stone masonry abutments and presented as much difficulty in maintaining good track as much larger spans for the reason that the dump ties were just as troublesome to keep up as the same ties on a 150-ft. span. I know of no greater use for flat slab bridges than in the replacing of these upon open floor I Beam spans. It is usually possible to remove these I Beams and replace them with flat slab bridges, carrying the ballast across the bridge and making a uniform track surface. The I Beams can be used for other purposes or at least they have a salvage value that goes toward reducing the cost of the improvement. I have in mind a certain stretch of railroad of about thirty-six miles that has over twenty small openings from six to twenty-five feet made up with of I Beams with open floors. However carefully the track work was kept up it meant a bad riding track as each one of the bridges represented an unyielding space that was very noticeable to the travelling public.

There is no class of reinforced concrete construction, however, that is entitled to more careful and intelligent supervision in the construction of the same than flat slab bridge. When concrete began to displace stone masonry unfortunately the sole idea of constructing engineers was to see how cheaply they could build structures in concrete. Apparently many engineers were so anxious to prove the superiority of concrete in both cost and durability that they frequently sacrificed the latter for the former. It is generally recognized to-day that to produce satisfactory concrete construction it is necessary to use the utmost intelligence and care in the selection of the materials and the execution of the work. Unfortunately reinforced concrete construction has, in the past, been exploited from the commercial side rather than from the engineering. This, I think, was largely due to the various patented types of reinforcing material. Concerns marketing reinforcing material looked upon it from the commercial side only and furnished all sorts of information as to not only the good points of their particular shape or type of reinforcing but also formulæ and information as to the construction of reinforced concrete that would apparently enable any one, engineer or otherwise, to undertake the work of designing and building reinforced concrete structures. Happily, we are passing out of that stage of development and it is now being generally recognized that it is necessary to have engineers of experience and trained to correctly design any reinforced engineering structure.

POWERFUL FREIGHT LOCOMOTIVES.

Serious consideration given to railway economics has shown that specific locomotive design is a potent factor in operating expense reduction and it is to this fact that the difference in a fast passenger locomotive and a mountain freighter are due. In fact, the locomotive of to-day may be divided into many classes; each class calling for particular differences which have been developed and have proved that a locomotive designed for a certain class of work gives better results than one taken from another section of the line and applied to the same class of work.

Thus it is that the great wheat belt of Western Canada has called for a locomotive that will haul grain in that section to the best advantage, and the management of the Canadian Northern Railway have commissioned the Canada Foundry Company, Ltd., of Toronto, to construct twenty locomotives similar to the one forming the illustration to this article.

These monsters are among the largest locomotives operating in the Dominion, and differ, in the main, from smaller types only in their massive proportions and fuel-carrying facilities.

They are built for a standard gauge of 4 feet 8½ inches, and have a total wheel base (locomotive) of 25 feet 5 inches. The cylinders are of simple design. 24 in. by 32 in., and the boiler is of the extended wagon top with a working pressure of 180 pounds to the square inch; the boiler contains 272 two-inch tubes, while the smoke stack has a diameter of 17 inches.

When these machines were designed, the British Columbian Cabinet had not issued the edict that will compel all locomotives operating in that province to burn oil, hence, the fire grates of these locomotives have been designed to consume bituminous coal; but as they have been designed specially for wheat haulage in the prairie provinces, it is not likely that their fuel consuming facilities will have to be changed.

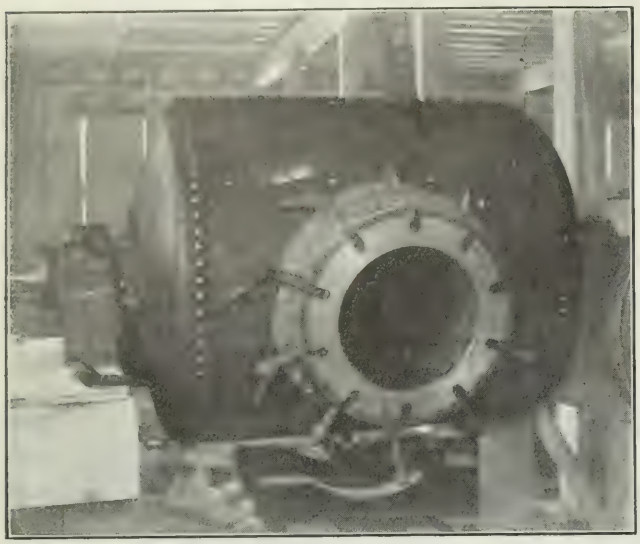
The driving wheels, of which there are six, have a diameter of sixty-three inches and a thickness of three and a half inches, the piston valves regulating the admission of steam to the cylinders have a diameter of twelve inches.

As may be readily seen from the cut, the design of the tender has been prepared in such a manner as to allow of exceedingly long haulages without stoppage for water or fuel; the water carrying capacity allows 6,000 imperial gallons to be taken at one time, together with ten tons of coal.

The total length of the engine and tender is about 65 ft.

THE HYDROLYSIS OF SAWDUST.

In a paper given recently to the Society of Chemical Industry, Professor W. P. Cohoe, of Toronto, gave an interesting resumé of his work on the hydrolysis of sawdust. The paper outlined briefly the history of the study of the reaction of various hydrolyzing materials on sawdust, beginning with the work of Bracconet in 1819. Most closely



View of Digester.

associated with the commercial study of this reaction are the names of Simonsen, Classen and Ewen and Tomlinson.

The work which the writer has done has extended over a period of two or three years, and although our attention has been chiefly confined to the action of hydrochloric acid upon sawdust, the action of many other acids has been studied.

The experimental work was conducted in three stages. In the first stage small scale laboratory experiments were made, in order to obtain in a general way the results which might be expected on a larger scale. In these experiments it was found that as high as 29 per cent. of the dry weight of the sawdust could be converted in a single operation into fermentable sugars. It was also found that by taking the material once treated and subjecting it to another operation, a further amount of this material could be converted also.

After having completed the small scale experiments, an apparatus was designed to enable the carrying out of experiments on a somewhat larger laboratory scale, under conditions more nearly approximating what would be the commercial conditions. On this scale it was found possible to treat about two pounds of sawdust at a time. On this scale the findings on the previous set of experiments were confirmed, and conditions necessary for a still larger scale anticipated.

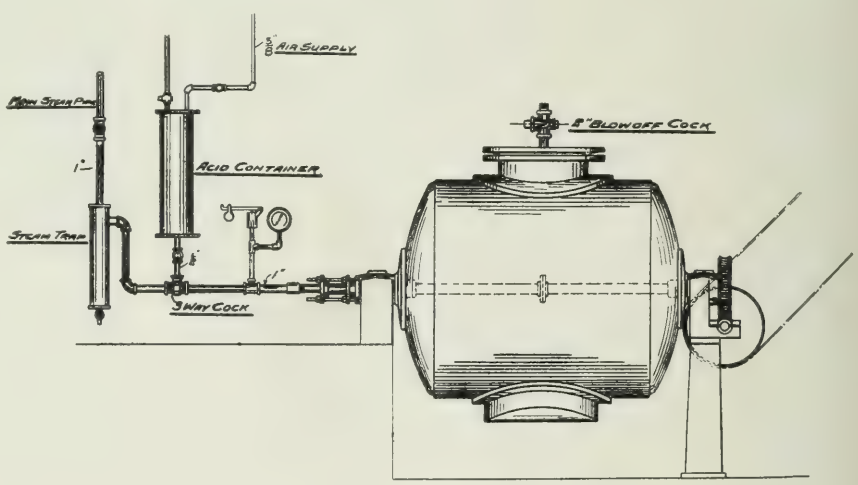
The third stage consisted of an operation on a semi-manufacturing scale. A digester was prepared capable of holding from eight to nine hundred pounds of ordinary sawdust. This was provided with a special lining, and also with the various necessary appliances for rotation and injection of steam and reacting materials, as shown in the accompanying diagram. The digester is filled when the manhole is in an upright position, after which it is closed. Steam is turned on, acting directly within the digester on the sawdust. The action of the live steam is to heat up the reacting mass inside, and to prepare it for the action of the reacting agent in the final stage. When the temperature and pressure conditions desired have been attained, the digester may be blown off in order to obtain any by-products which may have been formed. This part of the operation is known as the precook.

When the blow-off is complete the digester is again closed, steam is allowed to penetrate the mass, and with the steam is forced in the reacting agent. The action of the reacting agent is immediate, with the result that a certain percentage of the sawdust is converted into reducing sugars. The amount of this conversion depends on the temperature, pressure and percentage of acid present. We were successful in controlling these conditions to such an extent that the action hydrolysis was practically instantaneous, and it was only necessary to conduct the after cook for a sufficient length of time to insure a thorough mixing of the hydrolyzing agent with the contents of the digester. When blown off the sawdust has been converted into a golden brown color, resembling coffee grounds in appearance. This material may be extracted, and the extract, which contains glucose, may be fermented and subsequently distilled, in order to obtain alcohol, or, if it is thought desirable, the extract may be purified and clarified with the production of a pure white glucose sugar as the result.

The amount of the conversion which takes place from one operation varies from 20 to 40 per cent., depending upon the adjustment of the reacting phases. In no case, however, is all the converted material reducing sugars, as these are always accompanied by a certain percentage of what is probably intermediate materials.

As the result of our investigation several conclusions were reached which may be summarized as follows:

1. It is advantageous to have the sawdust heated up to the reaction temperature before introducing the acid.
2. A prolonged precook is not advantageous.
3. The recovery of valuable by-products, such as turpentine, is possible, using this method.
4. Coarse sawdust gives better results than fine.
5. By this method the time of conversion may be very much shortened over that consumed in existing methods, and consequently the output from a given plant may be very much increased.
6. Higher results have been obtained with hydrochloric acid than with other acids used by this method.
7. Commercial feasibility of the use of other acids.
8. Commercial advantage of double cook.



SKETCH OF DIGESTER.

THE DEATH OF MR. GEORGE A. KEEFER.

It is with regret that we hear of the death of Mr. George A. Keefer. Mr. Keefer was one of the original members of the Canadian Society of Civil Engineers, and two years after its founding was elected as councillor. He served five different terms in that position, and did much to help guide the Society over the rough spots of its early life. He was one of the older men of the engineering profession in Canada, men who did so much in the early days to open up the country by surveys and railroad construction. During the past twelve years he was employed by the Dominion Government in British Columbia. Mr. Keefer's death will be regretted by the members of the Canadian Society of Civil Engineers, and the engineering profession generally.

CONTRIBUTED ARTICLES.

The reader demands several things of a technical journal. "Good Roads," in a recent editorial, expresses sentiments on this subject which appeal to us as worthy of reproduction. One thing the reader demands is that a journal shall supply him with the general news of the field which it covers; another, that it shall place before him authentic accounts of particular events, such, for instance, as conventions; another, that it furnish him with descriptions, more or less detailed, of large and important works. But if we correctly understand the wants of our readers, the articles of the most real use to them are the accounts of work such as they, themselves, are called upon to do, written by those who have done the work. Such articles, telling how some difficulty has been overcome, what the cost of some operation has been, what success has attended the employment of some particular method, or what failure has resulted from the following of some plan, give information of everyday use.

The engineer engaged in actual work is in an excellent position to obtain the requisite data for interesting and useful articles. His thorough familiarity with the work enables him to arrange his facts properly and present them in the form most helpful to others. When he has done this he can submit it to the journal of his choice and be sure of a fair return for his labor if the article is accepted. And if it describes actual work, giving methods and costs in sufficient detail, he can be reasonably sure that it will eventually be printed.

As we have already stated, no journal receives too much matter of this sort. There are several reasons for this. In the first place, the man on the job is too close to his work to quite realize its importance; because it is his daily work he is prone to think it of too little consequence to be of interest to anyone else. In the second place, he does not always realize that he has anything to gain by preparing a description of the work as a whole, or of some special phase of it. And again, even if he realizes that such a description might be a source of profit to himself and others, he is apt to feel that he hasn't the ability to write an article.

None of these reasons is valid. The work that a man is engaged upon may not be of any particular interest, taken as a whole, and yet it may be of unusual interest in some of its details. For example, there would seem to be little of general interest in the construction of a bridge abutment; yet if some original and ingenious method were employed to deposit the concrete below

water level, that detail would be worthy of note. Again, while the construction of an ordinary country road might not appear to be of any particular interest, yet if an especially efficient contractor's plant had been employed in its construction, a description of the equipment and of the way it was used would be of unquestioned value.

As regards the matter of personal profit, it is only necessary to remind the reader that all reputable publications pay for contributed articles when they are submitted on that basis. The compensation, though not apparently large, will often prove greater in proportion to the time required to earn it than the engineer's remuneration for his regular work. In addition to the money return, there is the benefit accruing to the writer from the publication of articles carrying his name.

The objection having the least weight of all is the average engineer's lack of confidence in his ability to "write an article." While a contribution should, of course, be prepared to the best of the author's ability, its literary excellence is its least important attribute. The matter for technical journals is judged chiefly by the facts and figures it gives, and if valuable data are presented the language in which they are set forth is of minor consequence. The publication has a staff whose duty it is to look after that matter, and if the article is otherwise available, its form will be attended to.

PULP LIMITS.

Ontario must be congratulated on the business-like manner in which they are disposing of their remaining pulp limits. Tenders for the Abitibi pulp limits, consisting of 1,560 square miles of pulpwood, will be advertised by the Government in a few days in accordance with the programme announced some time ago in the matter of development and colonization of the north country.

The successful tenderer must establish a pulp mill to cost not less than $500,000, to produce 100 tons of paper per day, to employ not less than 250 hands, and to run on an average of ten months in the year.

According to the conditions, $100,000 must be paid down the first year, $200,000 the second year, and the remainder, $200,000, the third year. It is stipulated that the pulpwood cannot be touched until $100,000 is spent. After the mill is operated continuously there must be an average output of 75 tons daily. The lessee must pay 40 cents a cord for spruce and 20 cents a cord for all other woods, subject to increases from time to time by Order-in-Council. The wood must be cut in such a manner as the Minister may direct, and it will be further agreed that no wood will be exported. The wood must all be used to supply the pulp mills. Failure to erect the mills within the specified time will entail a forfeiture of the bonus, etc.

The successful tenderer shall be entitled to obtain a lease of the Iroquois and Couchiching Falls on the Abitibi River, and the right to control the water on Abitibi Lake, subject to the stipulations that may be imposed by the Minister. Also, plans for water storage and water regulations must be approved by the Minister.

Other clauses in the conditions infer that the Crown reserves the right to erect dams or enlarge the dams of the pulp mills, to develop power to the fullest extent, and charge a fair and equitable sum for the benefits conferred, the rate to be fixed by the Hydro-Electric Commission.

The T. and N.O. Railway will be entitled to the delivery of all surplus power to the extent of 10,000 horse-power.

No doubt in the early future the railway will be electrified, for this has been the ultimate intention of the Government and its Commission for some time.

COST OF SURVEYS.

The following statement shows the average cost per mile of surveys executed by surveyors under daily pay and by surveyors under contract is taken from the annual report of the Topographical Branch of the Department of the Interior:

	Surveyed under daily pay.	Surveyed under contract.
Total mileage surveyed	3,962	13,927
Total cost	$388,600	$376,477
Average cost per mile	$98.08	$27.03

The high average cost per mile of $27.03 for contract surveys as compared with $17.97 for 1909 is due to the fact that all the townships subdivided during 1910 were wooded while of those subdivided in 1909, 169 were open prairie; the relative rates per mile for surveys in open prairie and in solid bush are as $7.50 to $31.

The average cost per mile for surveys performed under day pay increased from $49.33 in 1909 to $98.44 in 1910. The average per mile for block outline surveys was $175 as compared with $167 in 1909. When the party under Mr. B. J. Saunders, D.L.S., is omitted from the calculation the average cost per mile for block outline surveys is found to be about ten dollars per mile lower in 1910 than in 1909. Mr. Saunders was compelled to abandon the survey of the nineteenth base line west of the fourth meridian when only a few miles had been run, but after all the initial expenses of organization, travel, etc., had been incurred. Other factors to increase the average cost of the surveys in 1910 were the larger number of parties working in the foot-hills in Alberta and in the railway belt in British Columbia and the smaller number engaged upon miscellaneous surveys, resurveys and restoration surveys in other parts of Alberta and in Saskatchewan and Manitoba. Owing to the nature of the country surveys in the foot-hills and in British Columbia are much more difficult than in the level and settled districts, and consequently slower and much more expensive. The average cost per mile of surveys in the foot-hills in Alberta during 1910 was $79, and in British Columbia $85, while the cost in Saskatchewan and Manitoba and other parts of Alberta was $33 per mile.

COMPARATIVE RATES FOR CURRENT.

The following is a comparison of electric current rates in four of the cities of Southwestern Ontario:—

London—Dwellings, 5c. per kw., less 10 per cent.; no minimum rate. Business, same.

Guelph—10c. per kw., less 20 per cent. Business, same.

Berlin—5c. per 100 sq. ft.; 4c. per kw., less 10 per cent. Business, 12c. per kw. for first hour of installed capacity; 5c. per kw. for additional, less 10 per cent.

Woodstock—3c. per 100 sq. ft; 4c per kw., less 20 per cent. Business, 10c. per kw. for first hour of installed capacity; 4c. per kw. for additional, less 20 per cent.

PROPOSED PEACE MEMORIAL BRIDGE.

A student of modern political conditions is conversant with the fact that mankind in general is cultivating an abhorrence of war between nations and communities. Examples have not been few during the past decade when the voice of the people has ended pending hostilities and bloodshed by declaring, through the columns of the press and by other means, that war must not yet be, and if difficulties have arisen, arbitration must be given every possible opportunity to restore a peaceful attitude.

There are two pronounced reasons for this; first the national mental expansion which has kept pace with the unprecedented industrial expansion of the past few years, and secondly, the overwhelming expenditure of public money following a declaration of war between two or more nations.

It may be a coincidence or it may be the natural succession of events, nevertheless, it is a fact that the three nations who have not resorted to a force of arms for over ninety-eight years to settle international difficulties, are the foremost examples of mankind, speaking in general terms, among the nations; these three are Great Britain, France and the United States.

Prominent citizens of the first and last mentioned nations have assumed that was is over between these communities, and, acting upon this assumption, have made preliminary preparations for a tangible celebration when the ninety-eight years shall be increased by two.

The two illustrations show in which direction the plans for the event have turned; the erection of a permanent bridge across the Niagara River between Canada and the United States of America.

The Niagara River is an ideal spot for such a structure on account of the prominence enjoyed by the Falls, the ease of distributing the foundations equally and the possibility of welding into its members the idea that it is an indestructible link that shall bind these two nations together for all time to come. Just at what spot the structure is to be built has not been decided, but that it will be either crossing the river close to Lake Erie or just below the Falls is very probable.

Fig. 1.—Proposed Memorial Arch Bridge at Niagara Falls.

Mr. T. Kennard Thomson, acting as consulting engineer to a committee of prominent men of both nations, has prepared the illustrations which we present to our readers. Figure 1 is a proposed structure to be erected and take the place of the present steel arch bridge a few hundred feet from the Falls. It has a clear span of 840 feet with a clear height of 144 feet, and the materials are steel encased in masonry; the design of the structure, both mechanically and aesthetically, has been prepared with a view of one hundred years' use.

The history of the bridges at this point has been somewhat varied, the first was a suspension bridge with a width just sufficient to allow one wagon to cross at a time; the second was of such a width that two wagons could cross, but the structure met an untimely end and fell a prey to a miniature hurricane which swept the structure from its anchorage. The third was, like its predecessors, of the suspension type, and it was removed to make way for the present structure, which is now considered too light.

Figure 2 is an illustration of an alternative proposed bridge, and is of a much more pretentious nature, having a length of nearly 4,000 feet. The design of this bridge includes six main spans with a length of 300 feet clear each,

Fig. 2.—Proposed Alternative Memorial Bridge Between Buffalo, N.Y., and Fort Erie, Ont.

and a height of 90 feet. The materials prescribed for this structure are granite with concrete backing. The width of this bridge is 100 feet, but a suggestion has been made that the structure be erected at Niagara-on-the-Lake, and should this be adopted the width will be reduced by 50 per cent. A beautiful boulevard is now being constructed from Niagara Falls southward, and it is very probably that this will be used as a connecting ling in connection with this driveway somewhere in the neighborhood of Fort Erie and Buffalo. In the design of this bridge Mr. Thompson received the assistance of Messrs. Griffin and Wynkoof, architects.

Mr. Thomson, in addition to being the consulting engineer of the committee, is a member of the Committee of International Organization and the Commerce on Memorials. He is a Canadian and a graduate of the class of '86 of the School of Practical Science, now the Faculty of Applied Science and Engineering, University of Toronto.

ASPHALT IN THE PAST YEAR.

Aside from its financial features, the annual report of the General Asphalt Company (owning the Barber, Trinidad and Bermudez Companies) issued May 14th, contains information of interest, especially to the paving and road-building industry. The total volume of business increased from $16,004,173.08 to $16,542,281.14. For the first time in the company's history the item "asphalt," which includes crude and refined asphalt and asphaltic products in all forms, exceeds the paving account. Sales of asphalt increased from 247,491 tons in 1910 to 265,677 tons in 1911. Thus while the consumption of asphalt increased in the amount just stated, and produced a revenue increase of $2,297,030, the paving done by the company shows a slight decrease, owing to the fact that a greater proportion of asphalt construction is done by customers of the company using Trinidad and Bermudez asphalts rather than by the company itself.

PUMPING DIAGRAMS.

The power required to pump a given quantity of water to a given height, when the efficiency of the pump is known, or how much water can be raised to a given height by the power available can be determined from the accompanying diagrams which were prepared by W. E. Wort for the American Machinist. These diagrams give the brake horse-power, number of U.S. gallons per minute and per hour, the pump efficiencies, and various heads in feet from 15 to 300 feet.

For example, if it is required to pump 350 gal. per min. against a total head of 85 ft. and the efficiency of the pump is 60 per cent., the brake horse-power is found by following the 350-gal. horizontal line to its intersection with the 85-ft. head diagonal, then following down the vertical line to its intersection with the 60 per cent. efficiency horzlontal line at the lower part of the table. It will be seen that 15 b.-h.p. is the power required for the duty specified.

Pumping Diagram, 100- to 300-ft. Head (U.S. Gallons).

THE HYDRAULIC RAM—ITS POSSIBILITIES OF DEVELOPMENT AND USE.*

By Stirling B. Hill.

The hydraulic ram was first invented by John Whitehurst, in 1772, and was made practical by Joseph M. De Montgolfer in 1796. The latter made the action of the waste valve automatic, thus changing the ram from a laboratory toy operated by hand, to a useful pumping device. Although the hydraulic ram was invented and used over 100 years ago, there was but little improvement in its design up to fifteen years ago.

To-day little is known of the hydraulic ram, even by engineers. The average engineer seems to have the most hazy idea of the characteristics of this much neglected pumping device. It is usually looked upon as a type of pump of small capacity and low efficiency, useful for pumping water for isolated dwellings, or where but a small quantity of water is needed and efficiency of no consequence.

Operation.—The essential features of a hydraulic ram are (See Fig. 1) supply or drive pipe A, ram chamber B, waste or impetus valve C, discharge or check valve D, air or equalizing tank E, and discharge or delivery pipe F.

The mere physical operation of the ram is simple, though the attendant phenomena and hydraulic principles involved seem to be but little understood. The general principle of operation is the same in all rams, however the mechanical workings and construction may differ.

Ignoring, for the present, the cause of the action, suppose the waste valve (C) to have just opened, the water in the drive pipe and ram being stationary, when the valve opens the water in the drive pipe starts to flow through the open valve, gaining in velocity, until the increasing velocity and pressure behind the valve are sufficient to close the latter. When the waste valve closes, the water flowing in the drive pipe with the momentum and energy of the moving column of water behind seeks another means of escape, which is secured by opening the discharge valve (D), flowing through the latter into the air chamber (E), and thence out through the delivery pipe (F). The air in the chamber acts as a cushion to the sudden inflow of water and maintains a nearly constant pressure in the chamber and steady flow through the delivery pipe.

The velocity gradually decreases until all the energy of the moving column of water is expended in forcing water into the air chamber and the flow ceases. The pressure in the air chamber then starts a back flow similar to the oscillation of water in a U tube. This instantly closes the check valve, thus retaining the water pumped. The tendency to back flow together with the sudden closing of the check valve, causes a momentary reduction of pressure in ram chamber (B), which allows the waste valve to open. The water then starts to escape as before and the cycle of operation is repeated. The action after once being started is automatic and the ram will continue to operate.

The back surge is usually sufficient to create for an instant a partial vacuum in the ram chamber. This condition may be taken advantage of, to introduce automatically into the upper part of the chamber a small amount of air at each stroke. During the waste period this air rises to the top of the chamber and at the delivery period is carried through with the flow into the air chamber. Thus the air supply is maintained, which otherwise would be gradually absorbed by the water under pressure.

* Abstract of paper read before the Pacific Northwest Society of Engineers.

Details of Operation.—The operation of the ram may be divided into two distinctive periods, namely, the acceleration or power accumulating period, and the retardation or pumping period. In the former, the waste valve is open and the water escaping through it, while the check valve is closed. In the latter, the waste valve is closed and the water is being delivered through the check valve.

In addition to the two periods mentioned there is the instant between the closure of the waste valve and the opening of the check valve, and also between the closing of the check valve and the opening of the waste valve. Each of these periods, though extremely short, has its distinctive functions and attendant phenomena.

We will now follow more in detail a cycle of operation or a stroke as it is commonly called.

When the waste valve opens the static column of water in the drive pipe, due to the inertia of its mass, cannot get up velocity at once, but is accelerated gradually. The time required to attain a certain velocity depending upon the ratio of supply head to length of drive pipe, or, stated in another way, upon the slope of the drive pipe. Neglecting the effect of friction, the acceleration is constant like that of gravity, and may be expressed in the familiar form $V = GT$, modified, of course, by the slope of the drive pipe, into $V = GT \frac{H}{L} = GT \sin A$, where A equals the angle of slope of the drive pipe, H equals the supply head and L the length of drive pipe. This is approximately correct for small velocities, but the friction varies as the square of the velocity, hence it soon becomes an element that must be considered. For any size pipe on a given slope there is a fixed possible maximum velocity. This is found by the Chezy formula $V = C\sqrt{RS}$ where S is the slope of the drive pipe, $\frac{H}{L}$.

Water Hammer.—Up to a certain point there is practically no resistance to the flow offered by the waste valve, as it will pass the water faster than it comes to it. After attaining a certain velocity, the water begins to head up behind the waste valve and when sufficient velocity and pressure are attained the waste valve is closed. When the valve starts to close the area of flow is further restricted, the pressure rises rapidly and the valve goes shut with a bang.

The sudden stopping of the moving column of water produces an instantaneous rise in pressure, causing what is called "Water Hammer." The intensity of the hammer is limited by the pressure against which the ram is pumping, as when this pressure is reached the discharge valve opens and prevents a further rise.

Experiments have shown that the maximum pressure in the ram exceeds that in the air tank by only a few pounds.

When the waste valve closes the lower filament of water is compressed, and is followed by each succeeding filament under like compression to the head of the drive pipe, while at the same time, the pipe walls due to this compression, are expanded. As this compression wave reaches the open end of the drive pipe, the first filament is relieved, then each in succession as a wave of rarefaction moves down the pipe. Thus the pressure waves race up and down ordinary pipe at a rate of about 4,000 ft. per sec. until worn out by friction.

The intensity of water hammer depends upon the velocity of flow and the rate of its suppression. If it is stopped instantly, the pressure developed is found by the formula, $P = \frac{vVW}{G}$ where P = water hammer pressure (in excess of static pressure) in pounds per square inch.

v = the velocity of wave motion in the pipe.
V = the extinguished velocity of the water.
W = weight of a cubic foot of water.
G = the acceleration due to gravity.

For ordinary conditions this would amount to about 60 lbs. for each foot of velocity extinguished.

Losses Involved in Ram Operation.—During the acceleration period the potential energy in the water supply entering the pipe is being changed into kinetic energy in the form of a moving mass of water, the power being accumulated and concentrated.

Without giving the matter consideration one naturally concludes that since water is running to waste, during the acceleration period, there must be a corresponding sacrifice of power and efficiency. This, however, is not the case, the only loss being the velocity head of discharge, which is usually but a fraction of a foot. The potential energy of this water has been stored in the form of kinetic energy in the moving mass of water in the drive pipe. When water power is used to raise water to a higher level it is self-evident that only a portion of the water can be raised to the higher level, hence, the remainder must be wasted at the lower level. For example, if a theoretically perfect machine were operating with a 10-ft. supply head and lift of 20 ft. ft. above the machine, it is evident that it would require two units of water with 10-ft. head to raise one unit 20 ft. The other unit is running to waste, yet no power whatever would be sacrificed, the machine in that case being 100 per cent. efficient.

The losses involved during the acceleration period are due to entry head, friction in the drive pipe, and the velocity head of the wasting water with the friction of its passage through the waste valve. These are all losses which can be determined definitely, hence the efficiency of the acceleration period is susceptible of accurate calculation when the co-efficients of friction for the design have been established.

In the case of the larger sized rams operating with medium drive head and moderate velocity the efficiency of the acceleration of power accumulating period may exceed 97 per cent.

The two periods of action are independent of each other, The action during the acceleration period is entirely independent of the conditions of delivery or retardation; that is, of the head against which the water is pumped. Likewise the retardation or pumping conditions are independent of the head used or time required in attaining a given velocity in the drive pipe.

The acceleration period ends when the waste valve is partially closed and the retardation period really commences before this valve is fully closed. The interval between this time and the opening of the check valve is really part of the retardation period though no water is pumped. The pressure is being raised in the ram accompanied by the water hammer effect.

A small amount of velocity is sacrificed in water hammer loss, the amount depending upon the head against which the water is pumped, or more directly the rise in pressure. The water pressure strikes the check valve suddenly and, due to its inertia, an increment of time is required to move it. This causes an instantaneous rise in pressure beyond that required to force the water through the valve and a small loss of efficiency is involved. The losses during the retardation period are: water hammer, opening discharge valve, friction through discharge valve, velocity head of discharge and slip of check valve at end of delivery.

Ram Capable of Mathematical Treatment.—Thus it will be seen that the action of the ram is capable of analysis and consequently of mathematical treatment.* When the various co-efficients have been determined by experiment for any given type of ram its performance under given conditions can be determined by calculation. The writer hopes later to acquire sufficient experimental data to be able to determine the proper value of the co-efficients.

Efficiency.—The efficiency of the ram is the product of the efficiency of the acceleration, or power accumulating period, and of the retardation, or pumping period.

There are two different formulas used for computing the efficiency of the hydraulic rams, namely, the D'Aubuisson and the Rankine formulas.

The former is expressed by the equation $E = \frac{q(H+h)}{(Q+q)H}$ and the latter by $E = \frac{qh}{QH}$ where:

E equals the efficiency of the ram.
Q equals the water wasted.
q equals the water pumped.
H equals the supply head.
h equals the pumping head above supply.

The D'Aubuisson formula represents the efficiency of the machine itself, as it considers all the water flowing through the drive pipe as the working force and the work done that of raising the water pumped from the ram to this point of delivery. If Q equals the total water supply and h the pumping head above the ram, then the formula takes the simpler form of $E = \frac{qh}{Qh}$.

The Rankine formula represents the useful work accomplished in raising the water from the level of the supply to the point of delivery.

The losses in the supply pipe are included with those in the machine itself in calculating the efficiency of the ram.

The efficiency of the ram depends upon the size of the machine and the conditions under which it is operating. The efficiency, under ordinary circumstances, of small rams varies from 50 per cent. to 70 per cent., and the larger sizes from 70 per cent. to 90 per cent.

With a properly designed ram, operating under favorable conditions, it is possible to obtain as high as 95 per cent. efficiency (D'Aubuisson).

Effect of Varying the Conditions of Operation.—Supply Head.—The effect of the supply head upon the operation of the ram is confined to the acceleration period. Other things being constant, the efficiency is increased by increasing the supply head. However, the same efficiency can be obtained with different heads by proportioning the velocity to the head.

With the higher heads, a greater velocity, with corresponding increase of capacity, can be used without sacrificing efficiency.

Consequently, the effect of increasing the supply head is to increase the capacity of economical operation, or, if the capacity remains constant, to increase the efficiency.

Pumping Head.—The effect of the pumping head is confined to the retardation, or pumping period.

Approximately the same efficiency during the retardation period can be obtained with any pumping head, but the velocity required to obtain this maximum efficiency increases with the pumping head. The efficiency, however, with

* Leroy Francis Harza, in his paper, "An Investigation of the Hydraulic Ram," published bc the University of Wisconsin, as Bulletin No. 205, gives a very complete mathematical treatment of the operation of the ram. He also carried out an elaborate series of experiments to check his theory.

which this higher velocity can be produced in the drive pipe will decrease; hence, the combined efficiency of the ram will decrease with an increase of pumping head.

If all other conditions remain constant, there is one pumping head for which the efficiency of the ram will be a maximum.

Length of Drive Pipes.—Other things remaining constant, the efficiency with which a given velocity can be produced in the drive pipe decreases as the length of drive pipe increases. This is due to pipe friction. The time required to attain a certain velocity with a given head increases as the length of drive pipe.

The efficiency during the retardation period is theoretically independent of the length of drive pipe. Practically, however, on account of the slip in the check valves and the loss in waste valve closure, it is not. The slip depends upon the frequency of the valve action, which, other things being fixed, depends upon the length of drive pipe. The longer the drive pipe, the fewer the strokes and less the slips.

The proportion of loss due to slip increases with the pumping head, both on account of the greater tendency to slip and the shortening of the delivery stroke. Therefore, a longer drive pipe is required for high heads than for low ones.

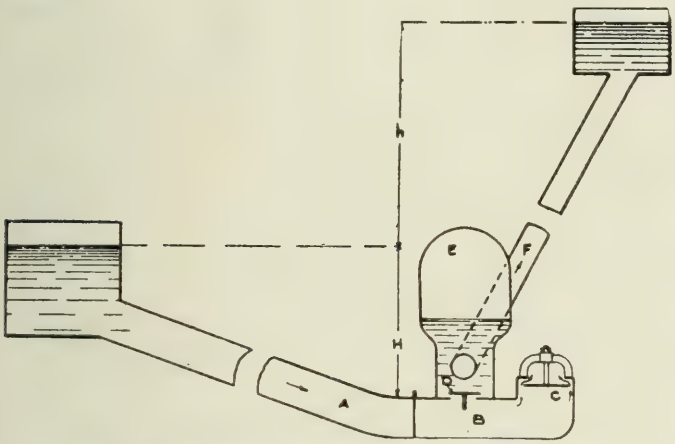

Fig. 1.—Essential Features of the Hydraulic Ram.

If the drive pipe is too long the friction is excessive, and if too short the slip is abnormal, hence there is for each size of ram with each combination of supply and delivery head a certain length of drive pipe that will produce the maximum efficiency.

There is also another working factor involved in the operation of the ram that has an influence on the minimum practical length of drive pipe. If the drive pipe is too short, or steep, the surging and vibration of the water column may interfere with the smooth operation of the valves, and the interfering waves will decrease the efficiency if the stroke is not carefully synchronized with the pressure vibrations. If too long a drive pipe is used, with the ordinary upward discharge, the automatic air supply will not work.

Size of Drive Pipe.—The main loss during the acceleration period is the pipe friction. During the retardation period the pipe friction is a minor loss. The efficiency of the ram will be increased by using the larger pipe, or a greater capacity will be secured with the same efficiency. The larger the size of the ram, with corresponding size of drive pipe, the greater the efficiency of the machine.

Strokes Per Minute.—Under any given conditions the capacity of the ram depends upon the velocity obtained in the drive pipe, and that depends upon the number of strokes per minute with which the machine is operating. The fewer the strokes, the greater the capacity, and the greater the number of strokes, the less the capacity.

A long, slow stroke allows the water to attain a greater velocity at each stroke and a corresponding greater average velocity, or flow through the pipe and ram.

For any given set of conditions there is a certain number of strokes that will produce the maximum efficiency. The efficiency increases with the number of strokes to a certain point, after which it decreases.

With a given supply head the efficient number of strokes increases with the pumping head to a maximum, and then decreases.

Limiting Factors.—The physical possibilities of the hydraulic ram are limited—first, by natural laws governing its operation, and, second, by human ingenuity in devising ways to make practical its possibilities.

Fundamental Limitations.—There seems to be no law law directly limiting the height of supply head that can be used, except that it must always be less than the lift above the ram. Let us, then, consider the pumping head. As stated before, the amount of pressure that can be developed by the sudden stoppage of water in the ordinary pipe is about 60 lbs. per sq. in. per second-foot of velocity stopped. Hence, the problem resolves itself into one of velocity obtainable in the drive pipe. In small pipes the limiting, or critical, velocity is soon reached. For example, a velocity of about 5.5 ft. only per second can be attained in a 1-in. pipe with a slope of 10 to 1, while in a 12-in. pipe with the same slope a maximum velocity of nearly 18 ft. per second could be attained. The practical operating velocity would probably be about two-thirds the maximum.

Thus it is apparent that, while a one-inch ram is limited to about a 400-ft. lift, under ordinary conditions, a 12-in. ram should be able to lift water at least 1,000 ft. The drive head that can be used must in each case be considerably less than the lift above the machine for practical operation. It is apparent that the fundamental limiting factors are beyond all practical requirements; hence, the problem resolves itself into one of practical design and mechanical construction.

Mechanical Limitations.—The design and operation of the waste valve seems to be the vital point. The ordinary hydraulic ram has an upwardly discharging waste valve of the disc type. The force of gravity—that is, the weight of the valve—is depended upon to open it and hold it open until it is forced shut, as previously described.

Machines of this type naturally have their limitations. Fifty feet seems to be the limit of the height of supply head that can be used. In the first place, the static head against which the valves will open is limited. They will not open with a long drive pipe or small ratio of heads. A moderate velocity will close them. For small rams, however, they answer very well. As the size of the disc valve increases, the area exposed to ram pressure increases as the square of the diameter, while the waterway around the circumference only as the first power. Thus the practical limit as to size is soon reached. This limit seems to be about 8 inches.

Certain manufacturers have lately cut the centres out of their discs and introduced light springs to assist the operation. This was quite an improvement, and they were enabled to increase the size of their machines, so that 12-in. rams may now be secured.

A Progressive Step.—Daniel W. Mead, now professor of Hydraulics at the University of Wisconsin, was the first to depart from the old rule-of-thumb design.

In 1895 he built and installed (under conditions that no ram manufacturer would attempt) a machine for the village of West Dundee, Illinois. In fact, no ram on the market today would operate under the same conditions.

This ram was installed with a 43-ft. drive head and 2,200 ft. of 10-in. cast-iron drive pipe. The makers assured Mr. Mead that such an installation was impossible, as the water hammer, due to stopping such a volume of water, would tear any machine to pieces. The ram was designed to suit the conditions; that is, with a large discharge valve area and with a very heavy spring to operate the waste valve, which was given a small movement. Needless to say, the machine operated successfully, and has continued to do so for the last 16 years.

The pressure in the ram exceeded that in the stand tower by about 2.5 lbs. There was no excessive hammer, as the column of water is not stopped or started suddenly, but gradually. This machine developed from 73 per cent. to 75 per cent. efficiency. This seems to be about the average efficiency of commercial rams in the larger sizes.

A New Type of Ram.—Last year the writer had occasion to investigate the subject of pumping machinery with a special view to the use of water power for its operation. The hydraulic ram, on account of its reasonable cost, automatic operation without the necessity of an attendant, low operating costs, durability and reliability, seemed particularly suited for use on irrigation projects, where conditions permit of its installation.

A particular case was presented to the writer some time ago for his consideration, where the supply head was so high that no ram obtainable would operate.

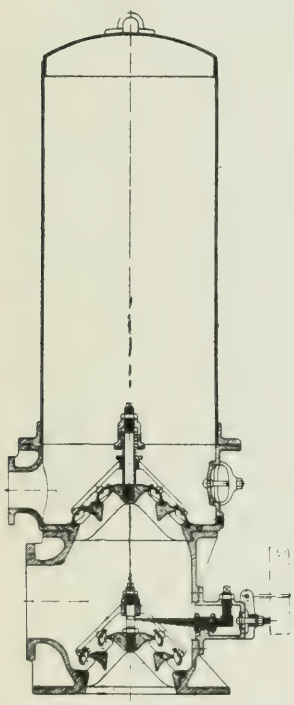

Fig. 2.—Section of 10-in. Sterling Ram.

After a careful study of the principles involved in the operation of rams, there appeared no fundamental reason why their operation should be limited to the narrow bounds of present practice. This being the case, it seemed that it should be possible to design a ram that would operate under a much wider range of conditions. With this idea in mind, a further investigation of existing makes of rams and their construction and operation was made.

It was apparent that a new type of waste valve was necessary in order to increase the strong, and have as large free capacity or field of operation of the ram. This valve must be so constructed as to eliminate the excessive hammer on its seat, must be light and strong and have as large free waterway as possible with a small movement of the valve.

The upward discharge was abandoned on account of the amount of head wasted on the larger sizes. The horizontal side discharge was considered, but passed because the machine would have to be submerged to above the valves to prevent their inhaling an excessive amount of air through the upper half of the valve during the fore part of the waste period. The solution seemed to lie in a balance valve of some description, having a downward discharge and operated with a heavy spring.

After numerous designs had been made and abandoned, a type of valve was finally evolved that seemed to fill the various requirements. This valve is composed of one or more concentric rings of increasing diameter, the number of rings depending upon the size of the machine. The plural rings are carried on a frame consisting of four radial arms, guided by a central stem, so they act as a single valve. The rings were changed from short cylindrical sections to ones having an arched cross section. See Fig. 2.

This allowed the water to escape over, as well as under, each ring when raised, thus nearly doubling the capacity of each ring with a given opening. This shape has the further advantage of offering smooth curved guides to the flow of the water and increasing the strength of the valve ring.

This arrangement of valves gives the greatest amount of clear waterway, with a minimum of weight of moving parts and space occupied, thus giving large capacity with high efficiency.

The valves being thin circular rings, with the vertical ram pressure practically balanced, they close very lightly, eliminating the excessive pounding. The hammer on the seats is the same in large rams, with this type of valves, as in the smaller ones, as they have practically the same shape and size of valve section.

A ram with valves of this type has been built and tested by Hill Bros. (See Fig. 2). It has a 10-in. supply pipe and a two-ring waste valve. The check valve is of similar construction, except that it has one ring and a central disc.

These valves, with a maximum movement of less than one inch, have an unobstructed opening nearly equal to the section of the supply pipe. The large efficient valve opening, with small movement of light valves, gives the machine large capacity without sacrificing efficiency.

The valve rings close on thick rubber seats consisting of a rubber ring inset in a dovetail groove in the metal seats. The rubber is forced into the groove and is just flush with the metal. This type of rubber seat cannot hammer to pieces as do other types of flat rubber packing seats having exposed edges.

The top of the valve ring closes flush with the outer edge of the valve seat above, the crack between being sealed with a rubber packing carried on the top of the valve. The valves are absolutely watertight, and constructed so they will remain so till the rubber disintegrates with age. The rubbers are easily renewed.

Test of 10-in. Sterling Ram.—The experimental machine was set up on the campus of the University of Washington, and a series of careful tests made under the supervision of the Department of Hydraulics. All measuring apparatus was carefully calibrated. A 50-ft. supply head was used and 140 ft. of 10-in. wrought-iron drive pipe.

The conditions were purposely made severe, the drive head being the highest yet used. The machine operated very satisfactorily, and the efficiencies developed were even better than anticipated. Various velocities were used, with lifts ranging from 100 ft. to 325 ft. The efficiencies ranged from 80 per cent, on the high lift, to 95 per cent. on the low (DeAubuisson formula). The drive pipe was too short to give the best results, especially on the higher lifts. Eight runs with a 115-ft. lift showed over 90 per cent. efficiency, the average being about 93.5 per cent.

It was hoped to secure a sufficient range of experiments to determine the characteristics and coefficients of the ram, but on account of the limited water supply available this proved impossible at the time. However, much valuable knowledge was obtained in regard to the fine points of ram operation.

A series of pressure indicator cards were secured on the ram, half way up the pipe and 20 ft. from the head of the drive pipe. These show the variations of pressure at these points. They seem to bear out the theory of the water hammer waves. The vibration in the drive pipe was very noticeable, especially near the head of the pipe, while in the ram

there was hardly any vibration. The indicator cards explain this. The ram cards show an almost constant pressure during the acceleration and retardation periods. The pressure rises very abruptly at the closure of the waste valve, but drops more gradually at the end of the delivery. The rise in pressure is almost instantaneous and scales less than 0.01 of a second in some cases. The closing of the check valve and the opening of the waste valve seems to consume from one-tenth to one-twentieth of a second of time.

Due to the throw of the indicator arm it was impossible to get a reliable record of the actual maximum pressure attained in the ram and drive pipe. In order to secure this data a special device was later made and used. It consisted of a small chamber on which the pressure gauge was mounted, a drain cock was provided in its bottom, and its connection to the ram, or pipe, was through a check valve and stop cock. The chamber contained air so that when the stop cock was opened the pressure vibrations pumped water into the chamber, compressing the air, the check valve preventing the return of the water. When the maximum pressure was reached in the chamber the water no longer was forced in. The gauge then indicated the maximum pressure.

The maximum pressure in the ram was found to exceed that in the air chamber from 3 to 4 lbs. After correcting for difference in the static head, the maximum pressure near the head of the drive pipe was found to be only 10 per cent. to 20 per cent. less than in the ram. The indicator cards show about the same result.

This shows that the stress in the drive pipe does not decrease uniformly from bottom to top, but is nearly constant the whole length. Consequently, the drive pipe should be designed practically full strength its entire length.

Possibilities.—Judging from the results of a careful study of the conditions involved, and observations of the operation of the ram described, it is believed the limits of the possibilities of operation and of capacity are beyond the ordinary requirements of practice.

Mr. Harza, at the conclusion of his paper, says: "If there is any reason whatever tending to limit the size and capacity of the hydraulic ram, it is the practical difficulties which might be encountered in the design of valves. It is believed that these are no more insurmountable than those encountered in the design of valves for other pumping engines of large size." It is believed that the proper valve required to solve the problem has been produced.

Head.—No difficulty should be encountered in operating these rams with supply heads from 1 ft. to 100 ft., and lifts from 5 ft. to 500 ft., the machines being designed to suit the service required.

In addition to the automatic hydraulic ram there is a current ram manufactured by the Lester Duplex Hydraulic Ram Co., of Portland, Ore. The waste valve in this machine is operated mechanically by a separate current wheel. The operating head for the ram is that produced by the velocity of the current of the ditch or stream in which the machine is set.

Capacity.—By the use of the multiple ring valve the size and capacity of the ram may be increased by adding more rings without changing any essential operating conditions. If the capacity is to be doubled, the length of valve ring, the unbalanced pressure on valves, the area of valve seats and the strength and resistance of the actuating spring are all increased in the same ratio. It is believed that rams having at least a 36-in. supply pipe can be built and operated successfully.

Uses.—The possible field of useful operation for the ram includes practically all those cases where water is to be pumped and local water power is available to furnish the power.

Water Works.—The ram is sometimes well adapted for pumping water for domestic supplies and city waterworks, as it operates continuously and efficiently without cost of attendance or power. Hydraulic rams in the past have been used mainly for supplying isolated dwellings and small villages. Now, however, the advent of this new type of ram makes these machines available for use in large city waterworks.

Irrigation.—There has been a great need in irrigation work for a cheap pumping machine that would work automatically, economically, and efficiently under all conditions, and having sufficient capacity to make them practical for large installations. Under some conditions the hydraulic ram is an ideal machine for the purpose. The new design makes possible the use of large units.

It operates automatically, no attendant being required. There are no bearings to oil and no moving parts exposed in the new design. It can be set up and operated miles from an attendant without housing or fear of molestation. It furnishes its own power without cost. The cost of maintenance is practically nil and the first cost of installation small. The machines are very flexible as to their operating conditions, the same machine operating equally well under a high or low head. The delivery head can be changed at any time without touching the machine or interfering with its continuous action.

The hydraulic ram could be included in the design of many gravity projects to advantage. Why construct the main gravity supply canal to the level of the highest land with the great additional length of canal and expense involved, when it is possible to locate the supply canal at an intermediate level using the power of the water dropped from the canal to the lower levels to raise the water to the higher levels? In many cases a great saving in cost could be made in this way and much difficult construction avoided.

On existing irrigation projects there are numerous cases where drops in canals and laterals can be used to operate rams to lift water to cover additional lands above the canals. In many instances the cost of the machines for this purpose would not exceed $3 to $10 per acre thus irrigated.

Mining.—The hydraulic ram is very well adapted for pumping water for mining operations. If there is water power available to do the work the ram is the cheapest and most economical pumping installation for the purpose. No fuel or power is needed, no attendant is required and there is practically no cost of operation. The rams will pump direct to the giant for hydraulic mining. Benches above the river bed could be economically sluiced by the use of these pumps to furnish the water required. It is often cheaper to install a ram for pumping than to construct a long gravity ditch, and much cheaper to maintain.

NEW METHOD OF UTILIZING HEAT FROM GASES.

Prof. W. A. Bone, F.R.S., Professor of Coal Gas and Fuel Industries at Leeds University, in a lecture at Leeds, described a new method of gas heating without flame, which, he believes, may work a revolution in fuel economy and have very important industrial effects.

Prof. Bone is one of the greatest living authorities on the subject of combustion. The new process has already been put into practical operation at Leeds. Hot surfaces promote the combustion of gases in contact with them, and it is on this property that the process is based.

AUXILIARY PLANT FOR POWER STATIONS.*

By A. H. Finch, M.A.

In this paper it is proposed to notice some of the points that should bear on the design of that part of a power installation which is referred to in general terms as the auxiliary system. In its widest sense, the term auxiliary might be taken to include everything except the principal agents involved in the cycle, which would mean practically everything except main engines, feed pumps and boilers.. More commonly the feed pumps are included as auxiliaries, which term will be taken to include also: (a) Thermodynamic appliances not essentially involving moving parts or power (e.g., economizers). (b) Apparatus requiring motive power independent of the main engines. Such a definition excludes transformers and certain small elements, such as oil pumps, which are often driven by the main engines.

The importance of this section of any large power plant is to be gauged by the proportion which it bears to the whole, whether in capital or running costs; figures are given subsequently which exhibit the ratio of auxiliary to main power in the case of some typical stations; but it presents a sufficiently accurate picture at this stage to say that in a modern power station of 30,000 kw. capacity the auxiliaries would account for 2,000 h.p., and probably £12,000.

To illustrate the divergence that can exist in the auxiliary equipment of a power station according to size and circumstances, it is only necessary to enumerate the apparatus employed. Thus it is possible to conceive of a station wherein the simplicity of the early marine engine is copied; where the boiler feed pump, air pump, and circulating pump are driven by levers from one of the main engine crossheads; a chimney produces all the requisite draft; ashes and coal are handled in all their stages by hand labor; and the exciter, if required at all is directly coupled to the generator shaft. Such a system, with the addition of a donkey feed pump or injector, is perfectly possible, and is approached, if not examplified, in many small stations. In fact, in non-condensing stations, a feed pump is the only really needful auxiliary. Its outstanding features are simplicity and thermodynamic waste.

In the opposite direction it is not unusual to find the following independently-driven pieces of apparatus: Exciters, feed pumps, air pumps, circulating pumps, exhaust (or other large) valves, cranes, ash hoists, coal hoists or conveyers, bilge pumps, boiler cleaning pumps, mechanical stokers, fans for induced draft, fans for generator ventilation, fans or pumps for cooling transformers, motor-operated switches, air exhausters for syphon circulating mains, air compressors for cleaning electrical apparatus, circulating water-straining appliances, economizer scrapers, oil pumps, and barring or engine-turning gear. Where what is known as a complete unit system is adopted, some of the above items are multiplied by the number of generators, resulting in an enormous aggregate installation.

Condensing Auxiliaries.

Assuming that for any condensing plant air and circulating pumps are required, it is of interest to consider the opportunity for simplification offered by the development during the last two or three years of rotary forms of air pumps. Whatever their merits or demerits as regards capacity for subduing air leakage on a system when contrasted with reciprocating pumps they possess two attractive attributes from the point of view of simplification in that (1) they occupy a very small space, and (2) they can be directly driven by any high-speed motive agent, whether electric motor or steam turbine. If it can be shown that they require no more maintenance than reciprocating pumps, which is reasonable to suppose from their exceedingly simple construction, a strong case for their adoption exists on these considerations alone. But where a complete use can be made of the exhaust steam, there is a further advantage in adopting a steam-turbine drive, as is shown in the following argument:—

Although such small turbines cannot be constructed to make any expansive use of steam below atmospheric pressure, by using the exhaust steam for feed heating advantage is at once secured even over a drive by electric motor. Let it be assumed that a small turbine is employed to drive on the same shaft the air pump circulating pump and water extraction or life pump attached to a main generating set. And for the sake of illustration let a plant of 3,000 kw. be considered. Then the power may be arrived at thus:—

Steam consumption, 42,000 lbs. per hour.

Circulating water, 65 times feed = 273,000 gallons per hour.

Head across circulating pump (for cooling tower conditions) 45 feet.

Power for circulating pump at 60% efficiency, 100 h.p.

Power for lift pump, dealing with condensed steam, and raising it 30 feet, with 50% efficiency, 1½h.p.

Power for air pump, 30 h.p.

Hence the power required for the combination is about 135 h.p.

At 35 lbs. per b.h.p. hour, the steam consumption of this auxiliary unit, exhausting at atmospheric pressure, is, therefore, 4,725 lbs. per hour. Such a quantity of steam would heat the feed water from 90 deg. to 200 deg. F. Thus the equivalent of $\frac{4725}{6.5}$ or 727 lbs. of coal per hour drives the circulating auxiliaries, and heats the feed 110 deg. F. The alternative, if electric drive be substituted for the small turbine, is 135 h.p. or 112 kw. at 3 lbs. = 336 lbs. coal for power, plus $\frac{4500}{6.5}$ = 692 lbs. of coal for feed heating. Total, 1,028 lbs. of coal as against 727.

Reciprocating air pumps are made with a high degree of efficiency, and may even take less power than the rotary type. But the power, small as it is in comparison with that of the main engine or turbine, is almost wholly dissipated in friction in reciprocating pumps, whereas it can be conserved in the form of heat in some forms of rotary pump, and where, as is the usual practice, separate motors or engines are used to drive the air and circulating pumps, the actual size of motor installed for a reciprocating air pump is settled by the consideration that a reserve of power must be provided in the motor, unless dangerously heavy fuses are used to deal with the case of flooded pumps, such as occurs after a stoppage (from any cause) while the prime mover is running. This means additional cost, and (in the case of induction motors) a bad power factor. No such reserve of power is necessary with a rotary pump. Consequently, the method of independent motors with reciprocating air pumps involves not only two motors instead of one, but that one of those motors should be larger than necessary. This arrangement, too, is likely to consume more energy than a single motor for the combination, and a fortiori more than the steam-turbine drive, if feed heating is placed to the credit of the latter.

* Abstract of paper read before the North-East Coast Institution of Engineers and Shipbuilders and printed in the "Transactions" of the institution.

It will be noticed that in the example given above, cooling tower conditions were assumed in calculating the power of the circulating pump. Their absence would have reduced the power for the pump from 100 h.p. to perhaps 60 h.p., depending on the location of the source of water. Natural-draft towers are responsible, therefore, for an appreciable increase in the motive power installation, and fan-draft towers for a considerable increase.

Economizers.

The question of economizers is almost entirely one of thermal efficiency. It is interesting, therefore, to note that they have been excluded from much important American practice. They are, on the other hand, used extensively in British and Continental work, though to very different degrees. Heating surface may be arranged for either in a boiler or outside it, with the qualifications that if in a boiler, it must be made of steel; but if outside, it can be made of cast-iron; and further, that gases cannot, in a boiler, be cooled below the temperature of saturated steam at working pressure, or in some cases superheated steam. In most designs of boiler these limitations result in a standard form, and a temperatutre of outgoing gases between 450 deg. and 600 deg. F. Such a standard form is accepted—and properly so—as being the outcome of the boiler-maker's experience; and the additional heating surface is arranged for apart from the limitation due to the presence of saturated or super-heated steam. But, while a certain uniformity is to be found in boiler surface provided for a given output, the number of economizer pipes may vary from nothing up to 12 per 1,000 lbs. evaporated. This variation in practice may be accounted for by the space available; but it is often influenced by consideration of the draft necessary.

Draft.

Draft may be created either by a fan or by a chimney. Where there are peculiar conditions such as the existence of long and tortuous flues, or the absolute necessity for drafts upwards of 1½ in., the question is settled automatically in favor of the mechanical method, practical considerations making it impossible to create a high draft by chimney alone. With a chimney the gases cannot be cooled below a certain temperature; otherwise insufficient draft will result. On the other hand, with a fan, gases may be cooled to any degree desired. Practical limitations are soon set in this direction by the space occupied by the economizer; and the result is that, though at first it might be expected that natural draft would necessarily be associated with smaller economizers than mechanical draft, in practice examples can be found of natural draft stations employing as large an economizer surface as even modern fan-draft installations. The mechanical arrangement has, however one advantage in facility of regulation independently of the weather, and in rendering a short chimney practicable.

The value of control over the draft cannot be assessed except in general terms by those who have had extended experience with both methods. Apart from this, the cost of power absorbed by the fans much outweighs the difference in capital charges due to a high natural-draft stack, as the following illustration, applicable to installations of about 10,000 kw. shows:—

For natural draft—	
Cost of chimney 250 feet high, with foundations	£3,000
For mechanical draft—	
Cost of chimney 100 feet high, with foundations	£1,200
Cost of fans and motors and extra flues.....	1,400
	£2,600
Balance of capital expenditure in favor of mechanical system	£ 400
Representing an annual charge, at 15%., of.....	£ 60
Against this is to be set running costs of motors, calculated on 200 h.p. for 5,000 hours at 0.25d. per unit	£ 780

The circumstances of load may, however, demand great elasticity in the steam-raising plant, in which case mechanical draft takes the place of additional boilers, and so may justify itself. Moreover, under normal conditions combustion is effected more economically with a high draft, if boiler and economizer surfaces are ample, less air of dilution being required per pound of coal.

The foregoing discussion is applicable only in cases where very moderate drafts are sufficient; and little variation is called for. The more usual case with an installation supplying power for general uses is that a certain latitude of draft is necessary for the purposes of the load, but the obstruction due to large economizers, coupled with the reduction at the chimney caused by lowering the temperature of the gases would result in insufficient difference of air pressure at the grate. In such cases the choice must be between natural draft with small economizer, or mechanical draft with large economizer; and the following treatment is put forward as being applicable.

The conditions assumed are as follows:—

Gases issue from boilers at.....	550° Fahr.
Air per lb. of coal, on average.....	23 lbs.
Temperature of atmosphere	60° Fahr.
Specific heat of products of combustion.....	0.25

In the case of fan draft, it is further assumed:—

Gases leave economizer and enter fan at..	320° Fahr.
Maximum water gauge required at fan.....	3 inches.
Usual water gauge required at fan.....	2 inches.
Efficiency of fan, 50% per cent. on average.	

In the case of chimney draft:—

Gases leave economizer at.....	450° Fahr.
Height of chimney	220 feet.

Then heat rejected from boiler per ton of coal fired is (2,240 × 24 × 0.25) × 490, or 6,585,600 B.T.U. In the case of chimney draft the economizer absorbs (2,240 × 24 × 0.25) × 100, or 1,344,000 B.T.U., and of this amount about 70 per cent., i.e., 940,800 B.T.U., is conveyed to the feed water, the balance being dissipated in flues, radiation and influx of cold air through economizer chain holes. In the case of fan draft, the power of the fan to create 3 in. water column, with an assumed efficiency of 50 per cent., may be found to be 16.6 h.p. per ton of coal burned per hour.* The usual h.p. required is, therefore, 16.6 × ⅔, or 11 h.p. per ton of coal per hour. The number of B.T.U. required to produce this energy, by way of boiler, turbine, alternator, transformer, and motor, with a combined assumed efficiency of 10 per cent., is $\frac{2,545 \times 11}{0.1}$ or 280,000 B.T.U. The quantity of heat usefully absorbed by economizer is (2,240 × 24 × 0.25) × 230 × 0.7, or 2,170,000 B.T.U. Consequently, of the total heat rejected from the boilers per ton of coal burned per hour, viz., 6,585,600 B.T.U., the natural-draft

* Height of column of heated products of combustion equivalent to 3 inches water column = 306 feet. Maximum horse-power required, with efficiency of 50%—

$$\frac{306 \times 24 \times 2,240}{60 \times 33,000 \times 0.5} \text{ or } 16.6 \text{ h.p. per ton per hour.}$$

method, with small economizer, realizes 940,800 B.T.U., while the fan method, with large economizer, realizes 2,170,000; less power to fan 280,000 = 1,890,000 B.T.U., or about double. Thermodynamically, therefore, under the assumed conditions, there is a gain of over 3½ per cent., really due to the use of the large economizer which is made possible by mechanical draft.

Next, as to the relative cost of the arrangements. This will vary in every case, and no two opinions on the matter will be the same. On the basis of an evaporation of 60,000 lbs. steam per hour, or a combustion rate of 3.84 tons of coal per hour, the capital cost of a fan installation with economizer of 9.6 pipes per 1,000 lbs. evaporated per hour, and short chimney, will be found to be, roughly, the same as for a natural-draft installation with 220 feet chimney and economizer of four pipes per 1,000 lbs., viz., £1,800. Capital charges can, therefore, be left out of a comparison, which might take the following form:—

	Per 60,000 lbs. Steam per Hour.	
	Mechanical Draft. £	Natural Draft. £
Saving of heat expressed as coal at 8s. per ton, 12,000 B.T.U. per lb., and 80% efficiency of evaporation.....	774	336
Maintenance	180	108
Power reckoned for 5,000 hours at 0.25d..	255	16
	435	124
	£339	£212

showing an advantage, in the case of mechanical draft, of £127 per annum. To this saving, which will obviously be greater still with greater load factors and in districts where coal is dear, must be added, for whatever it is worth, the convenience of being able to control draft independently of atmospheric conditions, and to force it to a degree unattainable with any chimney. It may be argued that this proposition depends entirely upon the manner in which the capital expenditure is made up. In the example cited above, variation of 25 per cent. in calculating the capital cost made, so as to swell the mechanical cost and reduce the other, would just about make the final results equal. But even in that case there would remain the practical advantages indicated.

Cost of Auxiliary Power.

Of more importance is the objection that an increase of the cost of power from 0.25d. to 0.38d. would extinguish the saving altogether. And this leads us to enquire what is the cost of power for auxiliary purposes. For most calculations it may be taken as the cost at generator terminals, plus some addition for transformation if necessary; less wages, as these are practically unaffected by the small proportion of output used on the station. The cost thus resolves itself into coal repairs and capital charges on generating and transforming plant. Many stations can now produce energy at 3 lbs. of coal per unit—some, of course, for much less—but at that figure and 8s. per ton the coal cost is 0.13d. Capital charges, at 15 per cent. on £15 per kw. with load factor 40 per cent., amount to 0.154d., repairs to 0.02d., making a total charge, for auxiliary power, of 0.304d. The figures adopted here are liberal with respect to good modern practice, and the price of 0.25d. assumed in former calculations, if low, is not by any means unattainable. On the whole, it would seem that the deciding factor in settling the matter of draft is the nature of the load. In isolated cases such a question as ability of the ground to carry a high chimney might be important—or again, the quality of ease in removal might recommend a short chimney and fan.

Feed Pumps.

It is only by elasticity of definition that feed pumps can be regarded as apparatus to render a thermodynamic principle advantageous. Yet they do not fall naturally into any other subdivision, being rather one of the main organs for carrying out the cycle. The power station designer has here a wide choice, between steam and electrical drive, and between reciprocating and rotating pumps. The latter possess many of the advantages of rotary air pumps already discussed, and practicable forms have been evolved. Such pumps, in respect of minimum wear, absence of valves, elimination of shocks to feed pipes and check valves, inseparable from reciprocating pumps, are almost ideal for power station work.

If a rotary pump can be combined with the circulating auxiliaries already described, and the whole be driven by a turbine on one shaft, a peculiarly compact and economical piece of apparatus results. There are naturally drawbacks in giving effect to this idea: one is that it may be difficult to find one speed suited to four different rotating objects; to a circulating pump, which may possibly have to deal with seventy times as much water as the feed pump, or to an impeller drawing against 29 inches vacuum and one delivering against 250 lbs. pressure.

Though not necessarily dependent upon rotary feed pumps, the closed-cycle system, whereby the feed water is at no stage exposed to the atmosphere, is rendered so much more attractive by their use that it may be noticed here. The idea underlying its application is that by reducing or altogether eliminating the aeration of the feed much trouble with economizers, feed pipes and boiler shells may be prevented. Since the feed is at no stage exposed to view as a current, it cannot be measured by the ordinary methods, and where anything more accurate than a Venturi tube test is required, an alternative arrangement of pipes must be installed for diverting the feed to the test tanks or recorders. For this reason it cannot be heated at atmospheric pressure, and surface heaters are, therefore, necessary. Then some elasticity is required between the discharge of the extraction pump and the suction of the feed pump to meet the case of boilers not requiring, minute by minute, exactly the same quantity as the steam condensed. And again, make-up feed for wastage has to be provided for. There are two or three methods of meeting these points. The simplest, but also the crudest is to provide a relief valve on the feed discharge, and regulate the admission of make-up feed to the condenser by hand. A more elegant suggestion, due to Mr. Sargent, and shown in Fig. 1, is to provide a tank into which the extraction pump delivers, and from which the feed pump draws. The tank is furnished with an overflow to a main reserve tank below, and a float mechanism controlling a make-up feed valve from reserve tank to condenser. When there is a surplus of water discharged from the condenser it overflows to the reserve tank, and when there is a shortage the float valve opens the connection from reserve tank to condenser. In this manner the system is rendered absolutely automatic, while the external make-up for wastage can be introduced by a float-controlled valve in the reserve tank fixed at a suitable level. By introducing the external make-up at this stage it becomes completely de-aerated before reaching the feed pump. Some stand-by pumping plant might be required for the case of banked fires.

In Fig. 2 is shown an alternative suggestion, proposed by Mr. Fullagar, with a tank floating, as it were, between the two pumps, but no provision is made here for de-aerating the make-up feed.

(To be continued.)

PROCESSES OF PULPWOOD MANUFACTURE.

In Quebec, seven-tenths of the wood used for pulpwood was spruce, balsam fir made up 28 per cent., and the remainder consisted of small quantities of hemlock and poplar. Both Quebec and Nova Scotia cut the four species used for pulpwood in Canada. No hemlock was reported from Ontario, in which province 90 per cent. of the consumption was spruce and the remainder was balsam fir. Spruce made up four-fifths of the consumption in Nova Scotia, balsam being used for practically all the balance. New Brunswick used spruce only.

Nearly four-fifths, namely, 78 per cent., of the pulpwood manufactured in Canada in 1910 was manufactured by the mechanical process; the sulphite process produced one-fifth, and the remainder (2 per cent.) was manufactured by the soda process. Quebec made 63 per cent. of the total mechanical pulp in Canada—more than twice as much as did Ontario. Of sulphite pulp, Ontario produced the most, although Quebec was a close second. The latter province manufactured over three quarters of the pulp made by the soda process.

Spruce, as in former years, was the chief wood used in each process. Over two-thirds (68.8 per cent.) was used for mechanical pulp; over one-quarter (28.7 per cent.) was made into sulphite pulp, and the remaining 2.5 per cent. was manufactured by the soda process.

Balsam fir has not yet been used in the soda process and is used to almost the same extent with the two other processes. The mechanical process consumed some 53 per cent. of this wood, while 47 per cent. was manufactured by the sulphite process. Eighty-four per cent. of the hemlock was manufactured by the soda process, which is adapted for most species of wood. One sixth of the hemlock was used to make mechanical pulp.

The physical properties of poplar wood do not adapt it for grinding by the mechanical process, and practically no poplar was manufactured by this process during 1910. It was used in almost equal quantities by the other two classes of manufacturers. Ontario manufactured a little by the soda process; only ground pulp was made in Nova Scotia; while New Brunswick produced small quantities of both sulphite and soda pulp.

Pulp manufactured by the mechanical process forms a greater percentage of the total during 1910 than at any time in the past. In the United States the percentage of ground pulp used is decreasing. The cause of the increase this year in Canada is probably due to the interruption of manufacture by the sulphite mills of New Brunswick. Unlimited supply of clean water is a necessity in the manufacture of wood by the mechanical process. A species of wood is also required which has a long loose fibre, which will not lose its shape and texture in the grinding. For these reasons Quebec with its spruce and balsam fir tracts and numberless waterfalls is the province best adapted for mechanical pulp manufacture.

Spruce furnished 83.2 per cent. of the wood used for mechanical pulp, and balsam fir contributed 16.6 per cent., with small quantities of hemlock and poplar making up the balance. The average cord of wood reduced by the mechanical process in Canada during 1910 produced 1,908 pounds of pulp. This is 257 pounds more per cord than was produced last year, but such comparisons depend greatly on the relative condition of air-dryness of pulp. Slightly over half this amount of pulp is produced per cord of wood by either the sulphite or soda processes, but the quality of texture is much better. The paper used in the average newspaper of to-day is composed of about twenty-five per cent. of sulphite fibre and seventy-five per cent. of the ground wood fibre made by the mechanical process.

In British Columbia, experiments are being carried on with the sulphite process, and, in 1910, 440 cords of spruce were used in the manufacture of paper. Seventy per cent. of the wood used in the sulphite process was spruce, mostly from Ontario. Balsam fir furnished 29 per cent., about three-quarters of which was from Quebec, and the same province used 1,800 cords of poplar to make sulphite pulp. The average production of pulp for every cord of wood used in the sulphite process during 1910 was 997 pounds.

Canada has the distinction of having the oldest soda mill in America, although the process is, at present, not in general use, and is found in only a few small mills. The production by this process, however, will shortly be increased by the completion of a large new mill, for the manufacture of 'Kraft' paper from soda pulp.

The soda process was the principal method used in the reduction of hemlock. Small quantities of spruce and poplar were also used in 1910. Balsam fir, however, is not suited to this process. Of the total, spruce formed 71 per cent.; hemlock, 19 per cent., and poplar, 10 per cent.

Quebec manufactured over three quarters of the pulp made by the soda process; 17 per cent. of the soda pulp was from New Brunswick, and 1,100 cords of poplar consumed by this method in Ontario made up seven per cent. of the total.

The average amount of soda pulp produced per cord was 987 pounds, or 10 pounds less than by the sulphite process.

The annual consumption of pulpwood per mill in Canada, during 1910, was 11,735 cords, as compared with a consumption of 12,442 cords per mill in 1909. The largest mills are those in Ontario, which used an average of 14,037 cords per mill. The average consumption per mill in Quebec was 13,710 cords; in Nova Scotia, 4,934 cords, and in New Brunswick, 3,783 cords.

Canada's foreign trade in pulpwood and wood-pulp is growing greater. Unfortunately, the tendency is still to export wood in the raw form of pulpwood rather than in the manufactured form of wood-pulp. This is a direct loss to the country, for the increased value due to manufacture is given away. In 1910, for the first time, $49,000 worth of pulp was imported into Canada, four-fifths of which was from the United States.

Although pulpwood production was less in Canada during 1910 than during the year previous, exportations of wood-pulp were increased by 48,233 tons. Wood-pulp exportations amounted in 1910, to 69.3 per cent. of the total amount produced in Can da, whereas in 1909 it was only 63 per cent. Of the 328,977 tons of wood-pulp exported, 288,807 tons, or 87.8 per cent., was mechanical pulp, which is a little greater percentage than in 1909. Only 78 per cent. of the pulp manufactured in Canada was mechanically prepared. While the increase in export for 1910 consisted of mechanical pulp, 1,173 tons more of chemical pulp also were exported in 1910 than during 1909. The 40,170 tons of chemical pulp shipped made up 12.2 per cent. of the total export.

The average value per ton of the pulp exported in 1909 was $14.67 for the mechanical, and $36.35 for the chemical pulp. This is an increase over the 1909 price of 70 cents for the mechanical, and a decrease of $2.64 for the chemical pulp. The average price for all pulpwood exported was $17.31, or 14 cents less per ton than the previous year's price. The prices per ton paid to Canadian exporters by the different importing countries were as follows for mechanical pulp: United States, $16.09 (exactly the same as in 1909); United Kingdom, $15.78 ($5.52 more than in 1909); other countries, $10.35 (37 cents more than in 1909). For chemical pulp: United States, $36.32; United Kingdom, $41.60; other countries, $38.30.

During 1910, over three-quarters of the wood-pulp exported went to the United States. This country took 74.3 per cent. of the mechanical pulp, and over 99 per cent. of the chemical pulp exported from Canada in 1910. Except for an increase of 3,000 tons of mechanical pulp to small transatlantic countries, export to other countries decreased. The export of chemical pulp to the United Kingdom has declined from 7,519 tons in 1908, to 178 tons (not one-fortieth as much) in 1910. The mechanical pulp shipped to the British Isles also decreased by 16,407 tons during 1910. The United Kingdom received in 1909, 32.5 per cent. of the mechanical pulp exported from Canada while in 1910, only 21.5 per cent. of the amount exported was used in those countries.

BRITISH COLUMBIA'S COAL MINES.

British Columbia's production of coal, estimated at 2,435,000 long tons, is 365,000 tons less than that of 1910. Coke also shows a decrease of about 140,000 tons; the output in 1911 was only about 78,000 tons as compared with 218,000 tons in 1910. The coal was produced in the several districts in the following approximate proportions:—Vancouver Island, 1,785,000 tons; Nicola Valley and Similkameen, 225,000 tons; and South-East Kootenay, 425,000 tons. Practically all the coke was from the last-mentioned district. The effects of the strike of the coal-mine and coke-oven employees on the production of coal and coke in the Crowsnest District, South-east Kootenay, has already been mentioned; in quantities of products it brought about this position: there was a decrease (net) of 605,000 tons of coal and 140,000 tons of coke. As the net decrease for the whole province was 365,000 tons, it will be seen that in other districts the decrease from the Crowsnest collieries was in part offset by increases in other parts—in the output of Vancouver Island, Nicola Valley and Similkameen coal mines.

Of the average yearly value of the mineral production of the province for the last five years, the production derived from coal and coke has been about 35 per cent. of the whole, while for the year 1911 it was nearly 39 per cent., and this despite the decreased output of the Crowsnest mines. It is true that the output of the collieries for 1911 is considerably less than for 1910, but the year 1910 was the record year in the history of coal-mining in the province, with a production valued at $11,108,335. The output for 1911, with its total value of $8,987,500, in the proportion of $8,522,500 for coal and $465,000 for coke, is second only to that of 1910, and is greater than that of any other year.

No branch of the mining industry of British Columbia appears to have a better prospect for expansion and consequent enlargement of production than that of coal-mining. A gratifying feature in this connection is that the promise of extending operations and increasing the output is general, that it appears evident that all the coalfields in which there has already been production may be expected to show a steady increase in output. That this is so will be manifest if attention be turned to local conditions in these several fields.

Briefly reviewing these conditions it may be noted that recent progress has been general. On Vancouver Island, the Western Fuel Company made the largest production in 1911 it has ever made; not only so, but a new mine is being opened, which it is expected will commence production next autumn, and be rapidly developed to a producing capacity of 1,200 to 1,500 tons a day. At the mines of the Canadian Collieries (Dunsmuir), Limited, there is also evidence of much progress, especially at its Union colliery, in the Comox District, where a new shaft mine is being opened and hydro-electric power for use at the mines is being developed. Production returns for 1911 have not yet been received from the last-mentioned company. It is expected the output of coal in 1911 was not less than 900,000 long tons. The Pacific Coast Mines, Limited, increased the output from its Fiddick mine at South Wellington, and further developed its Suquash mine in the northern part of Vancouver Island. The Vancouver-Nanaimo Company also made headway, for it arranged to provide shipping facilities at tidewater and to add to its coal-mining plant.

In both the Nicola Valley and Similkameen Districts progress was also noticeable, additions having been made to the coal-mining plants, and the output of coal in 1911 was larger. The Nicola Valley Coal and Coke Company increased its output from 141,000 long tons in 1910 to about 190,000 tons in 1911, and enlarged its coal-handling plant to a capacity of 1,000 tons a day. Three other coal properties in the Nicola Valley also had development work done on them in preparation for mining coal on a commercial scale, though as yet their production remains comparatively small. Coal was reached by a long crosscut tunnel on the property of the Columbia Coal and Coke Company, situated between Granite Creek and Collins Gulch, in the Tulameen Valley, and the work of equipping this mine with plant and machinery is in progress, while railway transportation has already been provided. At Princeton, the Princeton Coal and Land Company has made arrangements with a coal-mining machinery firm to supply a tipple and other equipment, the handling capacity to be 500 tons of coal a day and the plant to be ready for use early in 1912.

In East Kootenay, apart from the suspension of production while the employees were on strike, there were interesting developments. The Crow's Nest Pass Coal Company opened three or four practically new mines at its Coal Creek colliery, and it is claimed that from these a comparatively large quantity of coal of excellent quality can be mined. This company also did some effective prospecting at its Carbonado colliery, where new seams were found, and the work done on some of the old seams led to the hope that mines can be opened there in ground where the rock-structure is more favorable to mining coal. At the Hosmer colliery, of the Hosmer Mines, Limited, another level has been made along the outcrop of the coal-seams, about 500 feet above the level of the main entry to the mine, and facilities have been provided for transportation of the coal down to the main incline and thence to the shipping tipple. At the Corbin Coal and Coke Company's colliery an enormous deposit of coal has been opened at the surface and preparations have been made to work this coal open-cast, literally like a quarry. This most unusual occurrence of coal is situated at an elevation of from 800 to 1,200 feet above the main entry to the mine, in which latter the body of coal is also of great size, having a maximum width of about 300 feet.

There was little change in the situation affecting the large coal areas of the upper Elk River region of the Crowsnest District, described in the annual report of this department for 1909, for railway transportation has not yet been provided, and until it shall have been there will not be any commercial production of coal in that part of the province.

Concerning coal in the Skeena country—here, too, there can be no production until after railway transportation shall have become available. Public attention has been directed to what is known as Groundhog Basin, where the occurrence of much anthracite coal is known. A press bulletin, issued recently by the Geological Survey of Canada, gives information relative to this field, as follows: "Considerable interest has been manifested during the past seas-

on in the Groundhog coal-basin, which lies at the head of Skeena River. Probably 600 square miles have been staked and several groups of capitalists are interested in the field. Mr. G. S. Malloch, of the Survey Department, who spent the summer investigating the southern end of the basin on behalf of the Geological Survey, furnishes the following notes on this new coalfield:—

"'The coal-measures so far as known have a northwestward extent of at least seventy miles, and a width at the southern end of thirty miles. The sediments have a thickness of upwards of 3,000 feet, but contain coal in commercial quantities near the top and bottom only, though there are a few thin seams in the intermediate beds. The upper horizon contains seven seams with thicknesses varying from 2 to 6 feet, and, so far as is known, is limited to an area of twenty square miles. The lower horizon contains at least three seams 4 to 6 feet thick, and extends over most of the area occupied by the coal-measures.

The coal is anthracite in character. Some of the seams are high in ash, but from one of them some excellent analyses have been obtained. The basin is faulted considerably, and there are numerous local flexures associated with the faults. The development of a coalfield of this character near the Pacific coast would be of great importance to British Columbia. It lies about ninety (nearer 140) miles from tidewater at Stewart, Portland Canal, along a possible route for a railway, and about 150 miles from Hazelton on the Grand Trunk Pacific railway.'"

On Graham Island of the Queen Charlotte group prospecting of the coal-measures was done, but no coal was mined for the market. A Vancouver company bored for oil on the west side of that island.

With the considerable growth of the Coast cities there has been a correspondingly increased demand for building-stone, brick, lime, cement, etc. Various quarries from which granite, sandstone, andesite, and other building-stones are obtained had considerable demands made upon them. No marble was quarried at Nootka, but the marble-quarry situated about eight miles from the head of Kootenay Lake was re-opened and marble again shipped from it. The Vancouver Portland Cement Company, with works on Vancouver Island, made much cement.

PERSONALS.

MR. H. W. D. ARMSTRONG has been appointed to the position of chief engineer on the Gibson and Minto Railway.

MR. P. S. WEISBROD has been appointed to the position of superintendent of the Canadian Pacific Railway at Moose Jaw, Sask. He was formerly trainmaster at Cranbrook, British Columbia.

MR. ANGUS SMITH has been appointed to the position of city engineer for the municipality of North Vancouver, B.C. For over two years Mr. Smith has held a similar position in Victoria of the same province.

MR. ALEXANDER B. MANSON has been appointed to the position of city engineer for the municipality of Stratford, Ont. For some time Mr. Manson has been superintending construction work for the Canadian Northern Railway near Gowganda Junction, Northern Ontario.

OBITUARY.

MR. GEORGE ALEXANDER KEEFER, according to report received from Victoria, B.C., is dead. Mr. Keefer was a well-known civil engineer and was district engineer of the Department of Public Works of Canada in British Columbia. He entered the government service in 1872, on the preliminary surveys for the C.P.R. and the Rocky Mountains. For a time afterwards he was engaged on general engineering work in Vancouver, but since May, 1900, has been with the Dominion Government. Mr. Keefer was 76 years of age.

MEETINGS.

The regular meetings of the Western Canada Railway Club was held in the city of Winnipeg on the evening of April 8th last. A paper on "The Passenger Department," read by Mr. W. P. Hinton, general passenger agent of the Grand Trunk Pacific Railway, formed the major portion of the evening's programme.

In the course of his address the speaker stated that the organization of a general passenger department may be comparatively simple as it is on a small line or very complex, but nevertheless firmly welded together and carefully shepherded, on a large line. The department proper may be divided into the following branches: Traffics, tickets, excursions; statistics and accounts; train schedule and equipment; advertising; tourist, immigration and colonization; baggage; dining, sleeping and parlor cars.

A detailed description of the various sub-departments followed and concluded the paper.

CANADIAN RAILWAY CLUB MEETING.

The regular monthly meeting of the Canadian Railway Club was held in the city of Montreal on April 9th last. The speaker of the evening was Mr. A. R. Roy, Ph.D., who addressed the gathering on the subject of "Swedish Steel."

In the course of his lecture the speaker first defined steel as an alloy of impure iron and carbon, and then led his audience to a consideration of why one steel with similar apparent analysis possessed different qualities, and stated that there were three answers to this question.

1st. Incorrect analysis, showing equality, when not equal, of the composing factors of the various steels.

2nd. More skillful manufacture. This includes the better experience and practise of the workmen, as well as higher excellence of apparatus and mechanical conditions, such as fuel, etc.

3rd. The undetected presence of enchancing factors or beneficial elements.

The latter possibility received the major portion of the consideration on the part of the speaker.

It is noticeable, he continued, that iron brought from Spain, the Urals, America, Germany, France and Sweden produces different qualities of steel, although the analysis, so far as is known, is exactly the same and all other conditions equal and identical. Yet there is a decided difference in the quality of the steels, for one will do better than another when put to work on the same piece of material, at the same rate of speed, and given the same depth of cut and an equal amount of lubrication. All the composing factors of the steel are supposed to be equal in proportion. Where is the undetected factor?

Steel is a complex alloy, not merely of Fe. & C. but of the complex combinations of Fe. & C. known as Ferite &

Cementite, and Silicon as a base. To this, other elements such as Vd, Wo, Ni, Ti, Mn, etc., are added. Of these only C. & S. are found pure and free in nature but all of the elements can be separated at a certain stage in the laboratory. Iron is never found pure in nature. Late discoveries have detected various foreign elements in combination with iron. Therefore, it must be in the iron that the difference lies. Especially as the phenomenon of variance is found only between the steels produced with irons of different localities. In proof of which experiments have shown that Swedish steel or steels made from a Swedish iron ore base, are able to do more and better work than any other kind of steel. We also know that the Swedish iron ore, in its natural state, is freer from the detrimental combinations of sulphur, phosphorus and nitrogen, etc., than any other ore found on the European continent or America. But even when these harmful elements were removed or reduced to the proportions found in Swedish iron ore, the quality of the steel, although greatly improved, was not found equal to the product compared with, that is Swedish steel.

The presence of varying quantities of vanadium was given as the main reason for the variances.

COMING MEETINGS.

INTERNATIONAL RAILWAY FUEL ASSOCIATION.—May 22nd-25th. Annual Convention at Chicago, Ill. Secy., D. B. Sebastian, La Salle St. station, Chicago.

FOURTH NATIONAL CONFERENCE ON CITY PLANNING.—May 27th-29th. Meeting, Public Library, Boston, Mass. Sec'y, Flavel Shurtleff, 19 Congress Street, Boston, Mass.

AMERICAN WATER WORKS ASSOCIATION.—June 3rd 8th. Annual Convention at Louisville, Ky. Secy., J. M. Diven, 271 River St., Troy, N.Y.

CANADIAN ELECTRICAL ASSOCIATION.—June 19th-21st. Annual meeting at Ottawa, Ont. Sec'y, T. S. Young, 220 King St. West, Toronto, Ont.

SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION.—June 26th-28th. Annual meeting at Boston, Mass. Sec'y, H. H. Norris, Cornell University, Ithica, N.Y.

ONTARIO MUNICIPAL ASSOCIATION —Annual convention will be held in the City Hall, Toronto, on June 18th and 19th, 1912. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ont.

CANADIAN PUBLIC HEALTH ASSOCIATION.—Second Annual Meeting to be held in Toronto, Sept. 16, 17 and 18.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE: Secretary. Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, S. J. Chapleau, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving; Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, C. E. Cartwright; Secretary, W. Alan, Kennedy; Headquarters: McGill University College, Vancouver.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1290.

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydonejack; Meets every first and third Friday of each month, October to April, in University of Manitoba, Winnipeg.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION.—President, Chas. Hopewell, Mayor, Ottawa; Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm. Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, W. Sanford Evans, Mayor of Winnipeg; Hon. Secretary-Treasurer, W. D. Lighthall, K.C., Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, Mayor Mitchell, Calgary.; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALTIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, N. W. Ryerson, Niagara Falls; Secretary, T. S. Young, Canadian Electrical News, Toronto.

CANADIAN FORESTRY ASSOCIATION —President, John Hendry, Vancouver. Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewit, General Manager Consumers' Gas Company, Toronto; J. Keillor, Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President, J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary. H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, D. McDonald, Manager, Montreal Street Railway; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment. London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, Killaly Gamble, 703 Temple Building, Toronto.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, J. E. Ganier, No. 5. Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA —President, F. S. Baker, F.R.I.B.A., Toronto, Ont.; Hon. Secretary, Alcide Chausse, No. 5. Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J.R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, J. P. McRae; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Wm Pierce, Calgary; Secretary-Treasurer, John T. Hall, Brandon, Man.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, 115 Phœnix Block, Winnipeg, Man. Second Monday, except June, July and August, at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc. Printed forms for the purpose will be furnished upon application.

PLANS AND SPECIFICATIONS ON FILE.

The following Plans (P.) and Specifications (S.) are on file for reference only unless otherwise noted at the office of The Canadian Engineer, 62 Church Street, Toronto:—

Bids close		Noted in issue of
5-25—Sanitary sewer, Islington, Ont.	(P. & S.)	5-16
5-29—Water works, sewerage and electric light systems, Melfort, Sask.	(P. & S.)	5-2
6-10—Electrical equipment, Vernon, B.C.	(S.)	5-16
6-3—Electric Generating Station Equipment, Bassano, Alta.	(S.)	5-16

(Bassano specifications also on file at the office of The Canadian Engineer, Montreal).

(Melfort plans and specifications are also on file at The Canadian Engineer Offices, 820 Union Bank Building, Winnipeg, and B33, Board of Trade Building, Montreal).

(Vernon specifications are on file at The Canadian Engineer Offices, Winnipeg and Montreal; Canadian Electrical News, Toronto; Contract Record, Toronto; Mather, Yuill & Company, Limited, Consulting Engineers, Vancouver, B.C.)

TENDERS PENDING.

In Addition to Those in this Issue.

Further information may be had from the issues of The Canadian Engineer referred to.

Place of Work.	Tenders Close.	Issue of.	Page.
Australia, steel rails and fish plates	May 29.	May 2.	60
Bassano, Alta., electric generating machinery	June 3.	May 16.	66
Fredericton, N.B., wharf	June 4.	May 16.	60
Hamilton, Ont., castings, meters, etc.	May 30.	May 2.	72

Vernon, B.C., electrical equipment	June 10.	May 16.	72

TENDERS.

Bassano, Alta.—Tenders for electric generating station equipment will be received until June 3rd, 1912. Specifications at the offices of The Canadian Engineer, Toronto and Montreal. (See advt. in The Canadian Engineer).

Belbeck, Sask.—Tenders will be received up to noon of May 23rd, 1912, for plans and specifications for the erection of a 40,000-bushel elevator for grading-in purposes at Belbeck. W. H. Beesley, Box 74, Belbeck, Sask.

Berlin, Ont.—Tenders for waterworks improvements at Berlin, Ont., will be received by the Water Commissioners. (See advt. in The Canadian Engineer).

Kenora, Ont.—Tenders for the erection of a fire hall in the town of Kenora, will be received up to noon of Friday, May 31st, 1912. Plans and specifications at the Town Office, Kenora, Ont. M. McCulloch, Clerk.

Montreal, Que.—Tenders will be received until June 1st, 1912, for the construction of a steel and cement bridge over Bevan's Creek, in the Township of Arundel, Argenteuil Co., P.Q.; length of span, 50 feet. Plans and specifications may be seen at the office of Cushing & Barrow, 112 St. James Street, Montreal, or at the office of the secretary-treasurer. Wm. Thompson, secretary-treasurer, municipality of Arundel, Quebec.

Montreal, Que.—Tenders will be received by the Board of Commissioners, City Hall, up to noon of May 28th, 1912, for the construction of sewers on the following streets:—

Beresford Street, from Rushbrooke to Wellington.
Western Avenue, from city limits eastwards.
St. Charles Street, from Dorchester Street to its limits.
Sterling Avenue, from Cote Ste. Catherine Road to its limits.
Madison Avenue, from Sherbrooke Street northwards.
Belgrave Avenue, from Canadian Pacific Railway to Sherbrooke Street.
De Repentigny Street, River St. Lawrence to its limits.
De Grosbois Street, from Azilda to De Repentigny.
Bellevue Street, from De Rocheblave, 250 feet eastwards.
Lebrun Avenue, River St. Lawrence to its limits.
Cadillac Street, from Montreal Terminal Railway, to 1,100 feet north of Sherbrooke Street.
Fortune Street, from Wellington to Favard Street.

Full information can be obtained in the office of the Engineer Superintendent of Sewers. L. N. Senecal, secretary, Board of Commissioners, City Hall, Montreal.

Montreal, Que.—Tenders for the supply and delivery of granite and artificial paving blocks, will be received by the Board of Commissioners, City Hall, until noon of May 29th, 1912. Specifications, etc., may be obtained from the Sales & Purchasing Agent, City Hall. L. N. Senecal, secretary, Office of the Board of Commissioners, City Hall, Montreal.

Moose Jaw, Sask.—Tenders will be received until May 27th, 1912, for the laying of approximately 6,700 feet of 12-inch cast-iron pipe. Plans and specifications may be obtained from J. Antonisen, City Engineer. A. W. Maybery, L. W. Rundlett, W. F. Heal, City Commissioners, Moose Jaw.

Moose Jaw, Sask.—Tenders for cast-iron pipe and specials, will be received up to noon of June 1st, 1912, by the City Commissioners. (See advt. in The Canadian Engineer).

Moose Jaw, Sask.—Tenders will be received by the City Commissioners up to noon of June 1st, 1912, for the supply and delivery of valves and hydrants, f.o.b. cars, Moose Jaw. (See advt. in The Canadian Engineer).

Moose Jaw, Sask.—Tenders for the delivery f.o.b. cars, Moose Jaw, of sewer pipe and specials, will be received by the City Commissioners up to noon June 1st, 1912. (See advt. in The Canadian Engineer).

Ottawa, Ont.—Tenders for dredging Toronto Harbor, Ont., will be received until June 4th, 1912. Combined specification and form of tender can be obtained on application to R. C. Desrochers, secretary, Department of Public Works, Ottawa. (See advt. in The Canadian Engineer).

Ottawa, Ont.—Tenders for the construction of a pile wharf at Edmonton, Alta., will be received until June 17th, 1912. Plans, etc., at the offices of F. G. Goodspeed, Esq., District Engineer, Emonton, Alta. L. B. Elliott, Esq., Acting District Engineer, Calgary, Alta., and at the office of R. C. Desrochers, secretary, Department of Public Works, Ottawa.

Ottawa, Ont.—The Department of Public Works, Ottawa, is open to receive tenders for the supply of sorting cases for post offices, until May 30th, 1912. Plans, etc., to be seen on application to Mr. T. A. Hastings, Clerk of Works, Postal Station "F", Toronto and at the Department of Public Works, Ottawa.

Port Arthur, Ont.—Tenders will be called for shortly for the Sailors' Institute. Estimated cost, $30,000. Mr. Potter, Upper Canada Tract Society, Toronto, superintendent; F. Urry, Port Arthur, architect.

Regina, Sask.—Tenders for all of the works required and necessary in connection with the erection and completion of Westminster Church, Regina, will be received until May 27th, 1912. Plans and specifications may be seen at the office of N. R. Darrach, architect, Western Trust Building, city. J. J. McRae, Secretary, Building Committee, Box 455, Regina, Sask.

Regina, Sask.—Tenders will be received up to Tuesday, May 28th, 1912, for the construction of the following reinforcing concrete bridge work:—

Group 1.

(a) Two reinforced concrete bridge abutments for a bridge west of Lumsden.

(b) Two reinforced concrete bridge abutments for a bridge south of Estevan.

(c) Two reinforced concrete bridge abutments and a small reinforced concrete bridge south of Drinkwater.

Group 2.

(a) Two reinforced concrete bridge abutments for a bridge south of Webb.

(b) Two reinforced concrete bridge abutments for a bridge south of Maple Creek.

Group 3.

(a) Two reinforced concrete bridge abutments for a bridge east of Davidson.

(b) Two reinforced concrete bridge abutments for a bridge west of Dundurn.

(c) Two reinforced concrete bridge abutments for a bridge north of Asquith.

(d) Two reinforced concrete bridge abutments for a bridge north of Melfort.

Plans, specifications, etc., may be obtained on application to A. J. McPherson, Chairman Highway Commission, Regina, Sask.

Saskatoon, Sask.—Tenders for the erection and completion, with the exception of heating and plumbing, of a reinforced concrete office building to be erected on 2nd Avenue, Saskatoon, will be received until May 25th, 1912. Owner, Chester Thompson, Esq. Plans can be obtained at the architect's office, or the Builders' Exchange, Winnipeg. Frank P. Martin, Architect, P.O. Box 515, Thompson Chambers, Saskatoon.

Toronto, Ont.—Tenders will be received by W. J. Hanna, Provincial Secretary, Parliament Buildings, Toronto, up to noon, May 28th, 1912, for the delivery of coal as required in the sheds of the following provincial institutions, on or before the 31st day of August next, viz.: Brockville, Cobourg, Hamilton, Kingston, London, Mimico, Penetanguishene, Toronto, Hospitals for the Insane, Orillia Hospital for Feeble-Minded, Woodstock Hospital for Epileptics, also the Central Prison and Mercer Reformatory. Specifications of the qualities, etc., may be obtained on application to the department, or from the bursars of the respective institutions.

Toronto, Ont.—Tenders for concrete abutments for a bridge over a branch of the River Humber, Lot 2, Con. 11, Township of King, will be received up to five o'clock p.m. of Wednesday, June 5th, 1912. Tenders for concrete breakwater to protect the highway at or near Woodbridge in the Township of Vaughan, County of York, will be received up to five o'clock of Thursday, June 6th, 1912. Plans and specifications may be seen at the office of Frank Barber, Civil Engineer, 57 Adelaide St. East, Toronto. (See advt. in The Canadian Engineer).

Toronto, Ont.—Tenders for the construction of: (1) One quarry stone abutment for Islington bridge, over Mimico Creek, on Dundas Street, near Islington, and (2) for concrete truss superstructure for bridge over Highland Creek, near West Hill, Township of Scarboro, will be received up to five o'clock p.m., of Tuesday, May 28th, 1912. (3) Tenders for a concrete arch bridge over a branch of the Don on the Townline, Concession 3, between the Townships of York and Markham, County of York, will be received up to five o'clock p.m. of Thursday, June 6th, 1912. Plans, etc., at the office of Frank Barber, Esq., Civil Engineer, 57 Adelaide St. East, Toronto. (See advt. in The Canadian Engineer).

Vernon, B.C.—Tenders for the construction of approximately 50,000 feet of combined sidewalk and curb, will be received until May 27th, 1912. Plans and specifications can be obtained from the City Engineer's office, Vernon, B.C. D. G. Tate, City Clerk.

Vernon, B.C.—Tenders for the supply and delivery of 17,000 feet of 4-inch cast-iron pipe and 10,500 feet of 6-inch cast-iron pipe, will be received until June 10th, 1912. Specifications can be obtained from the City Engineer's office, City Hall, Vernon, B.C. D. G. Tate, City Clerk.

Vernon, B.C.—Tenders for the supply and delivery of 125 gate valves and 36 hydrants, ranging in size from 4-inch to 8-inch, will be received until June 10th, 1912. Specifications can be obtained at the City Engineer's office, Vernon, B.C. D. G. Tate, City Clerk.

Vancouver, B.C.—Tenders will be called for immediately for the construction of ten steel bridges along the line of the Canadian Northern Railway on the Fraser and Thompson Rivers. The bridge plans were designed by J. A. L. Waddell, City Engineer of Kansas City. The first one will be a 420-foot arch span across the Fraser, directly above the Canadian Pacific Railway bridge at Casco, a few miles below Lytton. Then comes a semi-cantilever bridge across the same river at Lytton. The entire cost of the bridges will be a million and a quarter dollars.

Winnipeg, Man.—Tenders for the erection of a court house in the city of Winnipeg, will be received up to noon of June 1st, 1912. Drawings and specifications may be seen at the office of the Provincial Architect, 261 Fort Street. R. P. Roblin, Acting Minister of Public Works, Winnipeg.

Winnipeg, Man.—Tenders for construction of a pile bridge (over Boundary Creek on the Gimli Road), and approaches thereto will be received until May 23, 1912. Plans, etc., can be seen at the clerk's office, Gimli; municipal office, Winnipeg Beach; Public Works Department, Winnipeg; J. D. Forster, secretary-treasurer, Winnipeg Beach.

Winnipeg, Man.—Tenders for the construction of reinforced concrete tunnels at the Agricultural College, St. Vital, will be received up to noon, of May 27th, 1912. Plans and specifications may be seen at the office of the Provincial Architect, 261 Fort Street, Winnipeg. R. P. Roblin, Acting Minister of Public Works, Winnipeg.

Yorkton, Sask.—Tenders will be received up to noon on May 29th, 1912, for the ventilating, plumbing and heating work in connection with the new west end public school building at Yorkton. Plans and specifications at the office of the architect. J. Pender West, 607 Somerset Block, Winnipeg, 9 Dunlop Block, Yorkton.

Barrett Specification Roofs

A CONCRETE CITY

Covered with Barrett Specification Roofs

IN the illustration below the Turner Construction Company, of New York, has brought together in a scale drawing an accurate representation of most of the important modern concrete buildings which they have erected during the past nine years, at an approximate cost of $12,000,000.

It is an imposing display of best types of modern construction—"*a concrete city*" indeed—scientifically designed for maximum service at minimum cost and minimum maintenance.

In the use of concrete, the designers of these buildings planned for economy—the real economy that results from adequate strength and no repairs.

Barrett Specification Roofs are a *real economy*, and it is significant that 95 per cent. of the entire roof area is covered with this type of roofing. The figures are as follows:

Barrett Specification type of Roofs	1,490,523 sq. feet
Plastic Roofings	14,714 sq. feet
Slate Roofings	21,640 sq. feet
Tile Roofings	5,619 sq. feet
Ready Roofings	38,381 sq. feet
Copper Roofings	6,355 sq. feet
All other kinds	7,448 sq. feet

It is important to remember that while all these buildings were constructed by the Turner Construction Company, the specifications were drawn by a large number of architects and engineers. That the great majority of these specified a Barrett Specification type of roof, emphasizes the fact that whenever this roof is practicable the best modern engineering practice will have no other kind.

These roofs were selected for one reason only, namely, that they would give *better* service at *lower cost*, than any other roof covering.

Barrett Specification Roofs require no painting or similar attention—in other words, there are no maintenance costs. They will last upwards of 20 years without any care.

That the above statement is conservative may be realized from the fact that roofs of this type have lasted, without attention, for thirty-five years, and are still in serviceable condition.

The superior economy of Barrett Specification Roofs justifies their adoption not only on big first-class concrete buildings, but on every flat roofed building from a tenement to a skyscraper—from a small mill to a modern manufacturing plant costing millions—but be sure it's a real Barrett Specification Roof—and the only way to be sure is to incorporate The Barrett Specification in full in your plans.

Copy of The Barrett Specification with diagrams free on request. Address our nearest office.

Montreal Toronto Winnipeg Vancouver St. John, N.B. Halifax, N.S.

CONTRACTS AWARDED.

Calgary, Alta.—Grant Smith and Company and McDonnell, of Vancouver, have been awarded a contract running into over $500,000 for the construction of a large reinforced concrete aqueduct two miles in length near Brooks.

Jansey Bros. and Boomer and Hughes, of Calgary and Spokane, have been awarded a two-year contract amounting to about $300,000 for the construction of a large number of reinforced concrete structures on the canal system in that section of the irrigation block lying between Bassano and Brooks and the Bow and Red Deer Rivers.

The Canada Foundry Company have also been awarded a large contract for the supplying and erection of 30 steel bridges of the main canal system, containing about 1,500,000 lbs. of steel, which, with masonry abutments, will provide practically permanent structures.

Calgary, Alta.—A very large contract has been entered into by Messrs. Jennings & Foster, owners of Lake View Heights, for improvements which call for an outlay of $95,000. They will build a concrete wall around the lake; also boulevards, parks, pleasure grounds and pavilion.

Fredericton, N.B.—Messrs. James H. Corbett and Sons have secured the contract for the construction of the sections of the St. John Valley Railway from this city to Gagetown and from Gagetown to Rothesay, a distance of 66 miles.

The contract for the building of the railway from this city to Woodstock, a distance of sixty-two and one-half miles, was awarded to the Quebec Construction Company, and the contract for the line from Woodstock to Centreville, a distance of about twenty-five miles, has been awarded to Messrs. Kennedy and MacDonald.

Goderich, Ont.—Extension to the north breakwater and dredging; contractor, Wm. Bermingham, Goderich.

Hamilton, Ont.—The Hamilton and Toronto Sewer Pipe Company, Limited, have secured the contract for a considerable quantity of sewer pipe at the town of Exeter, Ont.

Kent County, N.B.—Mr. Whitman Brewer has been awarded the contract for the construction of the James Jardine bridge. The contract price was in the neighborhood of $8,000.

Kamloops, B.C.—Two tenders were received by the city council for construction of cement walks. F. Walkley, $24,000, extra sidewalk 15c per square foot, extra crossings 40c. per square foot and curb 75c. Graff Construction Co., $21,985, extra walks 16c., crossings 14c., curb 40c. per lineal foot. It was decided that the contract be given the Graff Construction Company.

Lion's Head, Bruce Co., Ont.—Extension to wharf; contractor, J. E. Johnston and J. T. Crawford, of Wiarton, Ont.

Moose Jaw, Sask.—The following contracts have been awarded in connection with the Public Library: For heating and plumbing, Frost Bros., and for electrical wiring, the Acme Electric Company. The contract for the heating and plumbing was awarded for $6,695.70; to the Acme Electric for the wiring at $690. Other tenders for the work were the Alexander Plumbing and Heating Company, for plumbing and heating, $6,908; Moose Jaw Hardware Company for same work, $6,980.

Niagara Falls, Ont.—Contracts have been let for the construction of an addition to the plant of the Niagara Falls Canning Company. The papers were executed by Frank H. Boulter, the manager of the company, and call for the expenditure of $100,000.

Ottawa, Ont.—Machinery for 3½ yard dipper dredge; contractor La Cie Pontbriand, Ltd., Sorel, P.Q.

Port Colborne, Ont.—Post Office fittings; contractor, A. E. Augustive, of Port Colborne, Ont.

St. John, N.B.—Dredging in St. John Harbor, N.B., alongside the deep water wharf of the Intercolonial Railway. Contractor, J. S. Gregory, of St. John, N.B.

St. John, N.B.—Messrs. Norton, Griffiths & Company have let the $4,000,000 contract for construction of the mile-long breakwater to Messrs. MacDonald & Boheny, Alexandra, Ont., and G. T. Hervey, Montreal.

Toronto, Ont.—Contracts have been awarded by the Canadian Northern Railway for an electric railway connecting Toronto with Guelph and another line connecting Toronto and Bowmanville.

Vancouver, B.C.—City Engineer Fellowes has successfully recommended the acceptance of the following sewer tenders: Sewer on Keefer Street, Templeton to Union, to Messrs Bruce and Ford, $15,500; sewer on Sixteenth Ave., Manitoba to Ontario, to J. Shunn, $4,258; sewer to China Creek, Seventh to Twelfth Avenue, to the Graff Construction Company, $85,022.20.

Winnipeg, Man.—The following tenders were received and opened by the St. Boniface Council, for the construction of the trunk sewer on Dawson Street to serve the Public Markets, Limited.:

Van Horenbeck and Company, $147,650.75.
Marivet Cotteiner and Graham, $206,970.
Guilbault and Company, Ltd., $149,487.50.

The Van Horenbeck Company was awarded the contract, its tender being the lowest.

Winnipeg, Man.—The contract for the erection of the new St. John's College building, at a cost of approximately $40,000, has been let to Messrs. Worsick Bros.

RAILWAYS—STEAM AND ELECTRIC.

Galt, Ont.—Work has commenced on the spur extension of the Galt, Preston and Hespeler Railway. This will provide railway accommodation for the newly opened factory district.

Province of Manitoba.—A report states that work will be commenced on the line of the Grand Trunk Pacific to Brandon.

Montreal, P.Q.—Recent calculations made by the management of the Canadian Autobusses, Limited, who are negotiating for running rights into this city, show the fifty million persons must be carried to allow a margin of profit on the investment and pay a dividend of 6 per cent. to the shareholders. The company purposed investing five million dollars in plant and rolling stock in Montreal and employing two thousand persons, provided it obtained from the city an exclusive control for ten years. They will put on a service in four months of the date of signing the agreement with the city. In all 286 autobusses will be kept in continuous operation, and the company will have, besides, over sixty autobusses in reserve, bringing the total number to 350.

Saskatoon, Sask. — A report states that the Canadian Northern Railway are about to make a start on improvement work in this locality. The work includes the enlargement of the depot and freight sheds and a new yard. The plans for this work have been approved and the contract will be called in a few days.

South Western Ontario.—It is the intention of the Grand Trunk Railway to lay new 100-pound rails between Woodstock and Sarnia this summer. Sixty section men from Sarnia and points west of London, Ont., have been brought to the latter point, where the work is being started.

Windsor, Ont.—After several months' negotiations between the city and the Detroit River Tunnel Company an agreement has been arranged by which the original assessment of $2,500,000 placed by the Windsor assessor upon the property has been reduced to $444,444. This gives the city $10,000 a year in taxes.

LIGHT, HEAT AND POWER.

Beaverton, Ont.—The municipal council have applied to the Hydro Electric Commissioners for a specific volume of current. Beaverton is the first municipality in this district to make such an application.

Guelph, Ont.—The annual report of the Light and Heat Commission shows that this department has produced a profit of nearly $23,000 for the year ending December 31st, 1911. The following shows the manner in which this amount is made up:—

Total income	$110,188 35
Total expenditure	76,748 97
Net gain	$ 33,439 38
Debenture interest	10,738 85
Balance carried to credit of profit and loss account	$ 22,700 53

The income in the gas department was $55,495.34, and in the electric department $54,693.01. The total income was $110,188.35. Expenditures in the gas department were $37,603.59, of which salaries, $6,074, and labor (purification), $21,082.22, were the chief items. In the electric department's expenditure of $28,004.09, the cost of the Hydro-Electric power, $16,437.01, and $3,291.49 for general repairs were the chief items. There were $6,141.29 of general expenditures, depreciation $5,000, showing a grand total of $76,748.97 for expenditures. The balance sheet submitted by the auditors showed assets of $464,400.28, and total liabilities of $269,253.96, principally for debentures, due bank, city of Guelph and open accounts. The contingent fund for depreciation stands at $75,000, and there is a premium of $4,337.20, written up for reserve fund.

Saltcoats, Sask.—The municipal authorities of this town are about to issue debentures for the installation of electric light facilities. The estimated cost for this work is placed at $17,000. Mr. C. E. Boake is secretary-treasurer of this town.

GARBAGE, SEWAGE AND WATER.

Bordeaux Ward, Montreal, P.Q.—The ratepayers of this ward will get a supply of filtered water at an increase of three cents per 1,000 gallons more than the regular price for the crude article.

Berlin, Ont.—The Canadian Fire Underwriter's Association have made a report on the deficiencies in the town fire preventive appliances. In this report attention is drawn to the fact that the water supply is below the requirements of the number of residents and that the pumping facilities are below the amounts required for a single system.

Edmonton, Alta.—The new water filtration plant has been placed in working order, and is reported to be entirely satisfactory. The sedimentation basin has been repaired, and it is now expected that the water supply of the future will be received favorably by the ratepayers.

Montreal, P.Q.—The Board of Control has resolved to send a report to the City Council asking for an appropriation of $17,000 for the purchase of an engine and pump and the construction of a large reservoir tank, which will contain 200,000 gallons of water. The supply is for the higher levels of Montreal, which cannot be served out of the present upper reservoir.

Nanaimo, B.C.—The municipal council will give serious attention to a proposed increase in the water supply to the outer districts of the city.

North Bay, Ont.—Mr. John Shaw, C.E., has presented a report on a proposed water supply from Four Mile Lake, to the municipal council.

Four and one half or five miles of pipe are required in his recommendations.

This lake has an area of 208 acres and a depth of from 10 to 40 feet and with the watershed contains a sufficient supply for a population of 28,000 persons.

Vancouver, B.C.—Two 18-inch water mains have been placed in position for laying across the Second Narrows.

BUILDINGS AND INDUSTRIAL WORKS.

Courteney Bay, St. John, N.B.—The harbor improvements, etc., at this point, for which the Dominion Government has awarded a contract to Norton Griffiths and Co., Ltd., (Canada), are to be completed by March 30th, 1917, and embrace:

The construction of a breakwater 4,570 ft. long, including that of five groynes each 150 ft. long.

The dredging of a channel about 6,800 ft. long and 500 ft. wide at bottom to a depth of 32 feet below low water, from the main ship channel leading into the St. John River to the head of the breakwater mentioned above.

The dredging of a basin to a depth of 32 ft. below low water in Courtenay Bay.

The construction of about 4,890 lineal ft. of quay walls.

The filling of an area of about 28 acres.

The construction of a dry dock of the first-class.

Fort William, Ont.—A report states that an announcement has been made to the effect that the projected programme calling for the erection of a large plant of the Canada Car and Foundry Company in this city has now reached a definite stage and that work on the same will commence at an early date.

Fort William, Ont.—The members of the Fort William Rowing Club have arranged for the erection of a new club premises during the coming year. The cost of this work is estimated at $10,000. Mr. A. A. Wilson is the president of this organization.

Kenora, Ont.—The Public Works Department will commence the construction of a new dock at this point. The dock will cost about $11,800 and will be under the supervision of W. G. Earle, district engineer of this department.

Moose Jaw, Sask.—Mr. R. G. Bunyard has prepared plans for the erection of a new Roman Catholic school building to cost about $25,000. It will be of brick construction with a generous amount of stone trimming, 50 × 82.

Moose, Jaw, Sask.—Plans for the erection of a $60,000 Young Men's Christian Association building for this city have been prepared. It will be three stories in height.

Niagara Falls, Ont.—The American Cyanamid Company have decided to proceed with the extension of their plant. The work involves the expenditure of about $400,000 in reinforced concrete buildings alone.

Port Arthur, Ont.—The Ruttan Estates have begun the construction of a large block for stores and offices on Court St. Estimated cost, $80,000.

J. J. Carrick will erect a two-story brick block for stores and offices on south end of Cumberland St. Estimated cost, $30,000.

It is stated that the James Whalen interests will erect an office block on corner of Lorne and S. Water. Carl Wirth, of Fort William, architect.

Port Colborne, Ont.—Construction work on the plant of the Canadian Union Furnace Company will be undertaken in the course of a few days.

Stratford, Ont.—As soon as the plans for the new Grand Trunk passenger station have been approved by the Railway Board, construction work will be commenced. Mr. U. E. Gillen, superintendent of the middle division has the matter under his jurisdiction.

St. Catharines, Ont.—Messrs. Whitman and Barnes are about to commence building operations on an addition to their plant. The work will entail an expenditure of about $35,000.

Toronto, Ont.—The Engineers' Club have completed the purchase of property in this city, and will erect a new club house. The site of the purchase is near the corner of York and Richmond Streets, and has a frontage of 46 feet.

Vancouver, B.C.—Messrs. Braunton and Liebert, architects, will let the contract within the next ten days for the construction of a modern warehouse, five stories high, on Alexander Street, between Columbia and Main Streets. This building will be 50 feet × 125 feet, and will represent an expenditure of $125,000. It is to be of mill construction faced with with pressed brick.

Vancouver, B.C.—Plans have already been prepared and tenders will be invited in the near future for the erection of a fully modern apartment building on Hastings Street East, for Mr. J. A. Cockburn. This building will be 75 feet square and three stories in height.

Winnipeg, Man.—A report states that a start will be made on the new provincial legislative buildings this year. It is expected that the completed drawings of the successful architects will be finished by July 15th.

BRIDGES, ROADS AND PAVEMENTS.

Dauphin, Man.—The municipal council are making preparations for the construction of certain bridge works to be completed upon the sale of a bond issue now on the market. Mr. J. A. Gorby is secretary-treasurer of this town.

Port Arthur, Ont.—The municipal council have accepted the gift of a tract of land near the reservoir and will commence the construction of a driveway around it.

Moose Jaw, Sask.—The following tenders have been received by the municipal council and will be reported upon by the city engineer. The Bithulithic Paving and Contracting Company, Winnipeg, for $2.90 per square yard for bithulithic paving of five inch thickness, with additional cost of 30 cents per square yard for work between the tracks. The

THE TRIPLEX BLOCK

A Triplex Block hung from a temporary rigging and used for laying pipe.

What is the Life of a Triplex Block?

WE don't know. Triplex Blocks built by the Yale and Towne Co. at the very beginning—twenty-five years ago—are still in actual use. The Triplex Block of to-day possesses greater lasting powers. With its steel parts—its chain superior to any other—its non-wearing gear movement—and the guarantee of a rigorous test before shipment under a fifty per cent. overload. It will outlast the man who buys it, no matter how young he may be.

Fielding and Shepley of St. Paul, for 16 pound treatment creosoted wood paving at $2.84 per square yard, this being the lowest tender. Extra per yard between the tracks in this tender is 30c. The National Paving aind Contracting Company on sheet asphalt at $2.60 per square yard. R. Bangha, Windsor, Ont., at $3.44 per square yard for 2½ asphalt block with an additional 60c. per square yard for between the tracks.

FIRES.

Hamilton, Ont.—The factory of the Diamond Flint Glass Company was badly damaged by fire on the evening of May 18th last. The loss is estimated at $6,000.

Montreal, P.Q.—The premises of the British American Dye Works were damaged by fire on the evening of May 15th last. The damage was confined to the boiler room and the rear portion of the premises.

New Westminster, B.C.—The main factory of the Royal City Mills, together with two boiler-houses, landing platforms and docks, were burned early this afternoon. The loss will be in the vicinity of $100,000, fully covered by insurance.

Owen Sound, Ont.—The saw mill plant of the Carney Lumber Company was destroyed by fire on May 20th last, with a loss of $150,000.

CURRENT NEWS.

Calgary, Alta.—The Civic Industrial Bureau have appointed a committee to confer with the municipal council regarding the erection of an auditorium to house a display of "Made in Calgary."

Calgary, Alta.—The newly formed Tregillus Clay Products Company have awarded the contract for the supply of machinery to Bonnot Company of Ohio, U. S. A. This brick and tile company are arranging for the largest output of materials of this nature in Western Canada and are estimating 10,000 brick per hour as a reasonable output. These will be baked in twenty kilns of the down draft type. The raw material will be brought to the plant entirely by gravity, the location of the plant being admirably adapted by nature, and allowing for excellent drainage. Natural gas and the finest shales in this portion of Canada are at the disposal of the company.

Lethbridge, Alta.—A colony of seventeen ready-made farms will be established by the Canadian Pacific Railway near this city during the coming summer.

Montreal, P.Q.—Improvements to cost $2,000,000 will be begun on the Montreal harbor in a few days. They include the erection of a new 1,200-foot pier, the lengthening of several others, and the deepening of basin No. 1. The entrances to the Lachine Canal will be moved over in their entirety to a point opposite an open space between Mackay Pier and Windmill Point, which is being reserved for the Georgian Bay terminals.

Northern Canada.—The Clergue interests, which are promoting the proposed construction of the Nottoway River Railway, are sending up the steamer Baeotic with a party to make surveys, and the railway department is negotiating to send along a staff of engineers by the same boat to investigate further the question of terminals of the Hudson Bay Railway in connection with the proposal to have a second outlet from the Hudson Bay by way of a railway connecting James' Bay with the N.T.R.

Ottawa, Ont.—It is expected that competitive drawings and designs will be invited for the new Government buildings to be erected on the recently acquired Wellington Street site.

Prince Albert, Sask.—The ratepayers recently voted in favor of the following by-laws:—To raise $73,800 for extensions to the water mains; to raise $19,000 for storm sewers; to raise $21,500 for the city's share of granolithic walks; to raise $55,000 for common sewers. F. H. Creighton, city engineer.

St. Catharines, Ont.—The ratepayers approved of the concessions being granted to the management of the Warren Axe and Tool Company. The management will receive a free site and be exempt from certain taxes for a term of ten years.

St. Croix River, N.B.—Work has commenced on a dredging job that is designed to greatly improve the St. Croix River channel for a distance of four miles. The work is being carried on by the United States Government working under an agreement with the Canadian Government, each country paying a proportionate share of the cost and the Canadian Government maintaining an inspector on the work to protect its interests. The spoil is to be dumped into the river some distance below Mark Point, where the river has a depth of between 60 and 100 feet.

Sydney, C.B., N.S.—A report states that the management of a shipbuilding concern now carrying on negotiations with the municipal authorities of this city has made the following offer:—They ask a bonus of a million dollars in the shape of fifty-year civic bonds in instalments beginning when the plant is completed. They guarantee an expenditure of six millions, five dry docks, minimum of a million on shipbuilding plant. The dock proposed is to be 1,160 feet long, 44 feet at low water and 136 feet in width.

Thorold, Ont.—The head gates at Lock 24, of the new Welland Canal, at Thorold, had a narrow escape from being carried away on Sunday evening last. The steamer Beaverton entered the lock, bound up, when the steel cable that secured her broke and she drifted ahead and opened the head gates a foot or more, pushing them out of mitre. This allowed the water to rush through. This particular pair of lock gates kept back nearly a mile of water in the long and wide level that reaches south to lock 25.

TRADE ENQUIRIES.

The following were among the enquiries relating to Canadian trade received at the office of the High Commissioner for Canada, 17 Victoria Street, London, S.W., during the week ended May 5th, 1912:—

A Yorkshire firm of varnish, paint and color manufacturers, oil boilers and tar and rosin distillers are prepared to consider the appointment of Canadian agents.

A Scottish manufacturing firm producing all classes of paints and enamels, and specializing in export trade, are prepared to undertake Canadian business.

A Toronto correspondent desires to secure the agency of a United Kingdom firm manufacturing lines saleable to the drug trade from Winnipeg to Vancouver.

From the branch for City Trade Enquiries, 73 Basinghall Street, E.C.:—

A Midlands firm manufacturing springs of all kinds, also every variety of specialties in wirework and presswork, are looking for a suitable resident Canadian firm prepared to act as their buying agents.

A British firm manufacturing fancy metal photo frames, calendars, cigarette cases, and advertising novelties, desire to appoint a resident representative in Canada.

A German firm of merchants who have experience in chemicals and drugs, dyes and colors, glass and earthenware, machinery, metals and hardware, ores, scientific instruments, textiles, toys, etc., wish to enter into business relations with Canadian houses, either in a buying or selling capacity.

REGINA ENGINEERING SOCIETY WANTS CATALOGUES.

Mr. Edgar I. Wenger, Librarian of the Regina, Sask., Engineering Society, the formation of which was referred to recently in The Canadian Engineer, is starting a catalogue file for the use of its members and would be very pleased to receive trade literature of all kinds from manufacturers of machinery and engineering equipment generally. Mr. Wenger's address is Whitmore Building, Scarth Street, Regina, Sask.

CONCRETE SUB-CONTRACTORS WANTED.

We have about twenty thousand cubic yards of concrete work distributed in small bridges, abutments, head-gates, drops, etc., which we will let to responsible contractors in quantities to suit at good prices.

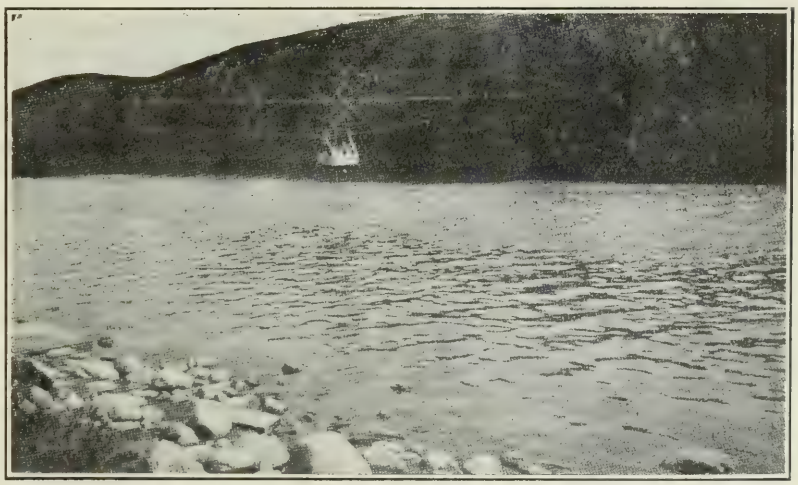
The Canadian Engineer

An Engineering Weekly

STREAM MEASUREMENTS.

In *The Canadian Engineer* dated November 3rd, 1910, was published an abstract of a report presented by Mr. P. M. Sauder to the Dominion Government on stream measurements in Alberta, Sask. Mr. Sauder, as chief hydrographer to the Government, presented his second Progress Report on Stream Measurements recently, and this report has just been issued. The methods used on the work are of interest, and we here present an abstract.

Moosejaw District.—For some time it has been realized that as the country becomes more thickly populated and the towns spring up, there are portions of the West which will not have a sufficient water supply for domestic and industrial purposes. The Council and Board of Trade of Moosejaw for 1909, were among the first to realize that while there is a sufficient water supply in the district, it is allowed to run off into the larger rivers, in the freshets, and the district is left with an inadequate supply during the remainder of the year. They petitioned the Government to investigate and report on the resources of the Moosejaw Creek and the best methods for the development of same.



Cable and Car on Elbow River, at Calgary, Alta.

Two gauging stations were established on the creek; one at a bridge on the N.W. ¼ Sec. 16, Tp. 16, Rge. 26 W. 2 M; and the other at a bridge on the road allowance between Secs. 14 and 15, Tp. 15, Rge. 25, W. 2nd Mer. Daily records were obtained at these stations, and the total annual run-off computed. A careful stadia survey was made of the valley from Moosejaw to a point a few miles above Rouleau, and a map showing the configuration of the surface of the ground by contours of 10-foot intervals, was prepared. While the topographic survey was in progress, a careful reconnaissance was made to discover the most inviting places for the location of dams and reservoirs. Cross-sections were taken at four dam sites offering the best opportunities for storage. The contour map shows the lands which would be flooded by the erection of a dam of any feasible height and tables showing the flooded areas and capacities of the reservoirs were also prepared. A report of this survey is given under the heading of Moosejaw Creek Drainage Basin.

The water supply in the vicinity of Regina, Moosejaw, and along the Soo Line of the Canadian Pacific Railway is limited and it is very important that we should continue a study of the regimen of flow of Moosejaw Creek for several years. This district will be extended during the coming year to include Souris, Qu'Appelle, and South Saskatchewan Rivers. Souris River, which heads in Canada, crosses the International boundary into the United States and then recrosses into Canada and finally empties into Assiniboine River east of Brandon. This river traverses a large territory in Canada and is the only stream in that district. It is proposed to divert it for irrigation purposes, in North Dakota, which may affect Canadian interests.

In all investigations of water resources the most important factor is the available supply. It is also the factor that requires the longest time to determine satisfactorily, owing to the great fluctuations in stream flow from year to year. The stream gaugings already undertaken should, therefore, be continued for a number of years in order that the records may be long enough to show extremes of flow as well as a reliable mean.

The low flow of 1910 has demonstrated the part that municipal water supply and sewage disposal have in the use of rivers and therefore data should be compiled to show the amount of such water supply and sewage and the source of the former (where in surface waters) and the disposal of the latter.

I do not think it necessary to elaborate on the importance of continuing observations during the winter on the more important streams. The minimum flow occurs during that season and should be determined for use in considering power schemes.

Next in importance to a knowledge of the available water supply is a knowledge of the fall of the streams, and the possibilities of storage. This is necessary to determine the value of the river for irrigation, water power, as an outlet for drainage ditches, and as an available channel for flood prevention work. River profile and reservoir site surveys should therefore be commenced as soon as possible on the more important streams of the West.

Definitions.—The volume of water flowing in a stream is known as run-off or discharge. In expressing it various units are used, depending upon the kind of work for which

the data are needed. Those used in this report are "second-feet," "acre-feet," "run-off per square mile" and "run-off in depth in inches" and may be defined as follows:

"Second-foot," is an abbreviation for cubic foot per second and is the body of water flowing in a stream one foot wide and one foot deep at the rate of one foot per second.

The "acre-foot" is the unit capacity used in connection with storage for irrigation work, and is equivalent to 43,560 cubic feet. It is the quantity required to cover an acre to a depth of one foot.

The expression "second-feet per square mile" means the average number of cubic feet of water flowing each second from every square mile of drainage area on the assumption that the run-off is uniformly distributed.

"Depth in Inches" means the depth of water in inches that would have covered the drainage area, uniformly distributed, if all the water could have accumulated on the surface. This quantity is used for comparing run-off with rain-fall, which quantity is usually given in depth in inches.

It should be noticed that "acre-feet and depth in inches" represent the actual quantities of water which are produced during the periods in question while "second-feet," on the contrary, is merely a rate of flow per second.

Explanation and Use of Tables.—The data obtained and the estimates made therefrom have been compiled in tabulated form and for each regular gauging station are given, as far as available, the following data:—

1. Description of station.
2. List of discharge measurements.
3. Daily gauge height and discharge table.
4. Table of monthly discharges and run-off.

The description of stations gives such general information about the locality and equipment as would enable the reader to find and use the station. It also gives, as far as possible, a complete history of all the changes that have occurred since the station was established and that might affect the records in any way.

The list of discharge measurements gives the results of all the discharge measurements that have been made at or in the vicinity of the gauging station or have been used in completing the records for the gauging station. It gives the date on which the measurement was made, the name of the hydrographer, the width and area of cross-section, the gauge height and the discharge in second feet.

The table of daily gauge heights and discharges given in this report is a combination of two tables kept in the office of the survey, namely, the table of daily gauge heights and the station rating table. The table of daily gauge heights gives the daily fluctuations of the surface of the water above the zero of the gauge, as reported by the observer. During high water, two observations of the gauge were made at some stations and the gauge height given in the table is the mean of the observations for the day. The discharge measurements and gauge heights are the base data from which the other tables are computed. The table of the daily discharges is the discharge in second-feet, corresponding to the stage of the stream, as given by the station rating table.

In the table of monthly discharge the column headed "Maximum" gives the mean flow for the day when the mean gauge height was highest. As the gauge height is the mean for the day, there might have been short periods when the water and the corresponding discharge were greater than given in this column. Likewise, in the column "Minimum" the quantity given is the mean flow for the day when the mean gauge height was lowest. The column headed "Mean" is the average flow for each second during the month. The computations for the quantities in the remaining columns have been based upon this mean. The drainage area for each gauging station was marked off on the sectional maps of the Department and the area taken off with a planimeter. In many districts, information regarding topographical features is very incomplete and the computed areas are only approximate. As the surveys of the Department are extended and completed these computations will be checked and, if necessary, corrected.

Convenient Equivalents.—The following is a list of convenient equivalents for use in hydraulic computations:—

1 second-foot equals 35.7 British Columbia miner's inches, or one British Columbia miner's inch equals 1.68 cubic feet per minute.
1 second-foot equals 6.23 British imperial gallons per second; equals 538,272 gallons for one day.
1 second foot equals 7.48 United States gallons per second; equals 646,272 gallons for one day.
1 second-foot for one year covers 1 square mile 1.131 feet, or 13,572 inches deep.
1 second-foot for one year equals 31,536 cubic feet; equals 724 acre-feet.
1 second-foot equals about 1 acre-inch per hour.
1 second-foot for one 28-day month covers 1 square mile 1.041 inches deep.
1 second-foot for one 29-day month covers 1 square mile 1.079 inches deep.
1 second-foot for one 30-day month covers 1 square mile 1.116 inches deep.
1 second-foot for one 31-day month covers 1 square mile 1.153 inches deep.
1 second-foot for one day equals 1.983 acre-feet.
1 second-foot for one 28-day month equals 55.54 acre-feet.
1 second-foot for one 29-day month equals 57.52 acre-feet
1 second-foot for one 30-day month equals 59.50 acre-feet.
1 second-foot for one 31-day month equals 61.49 acre-feet.
100 British Imperial gallons per min. equals 0.268 second-foot.
100 United States gallons per min. equals 0.223 second-foot.
1,000,000 British Imperial gallons per day equals 1.86 second-feet.
1,000,000 United States gallons per day equals 1.55 second-feet.
1,000,000 British Imperial gallons equals 3.68 acre-feet.
1,000,000 United States gallons equals 3.07 acre-feet.
1,000,000 cubic feet equals 22.95 acre-feet.
1 acre-foot equals 43,560 cubic feet.
1 acre-foot equals 271,472 British Imperial gallons.
1 acre-foot equals 325,850 United States gallons.
1 inch deep on 1 square mile equals 2,323,200 cubic feet.
1 inch deep on 1 square mile equals 0.0737 second-foot per year.
1 acre equals 43,560 square feet.
1 cubic foot equals 6.23 British Imperial gallons.
1 cubic foot equals 7.48 United States gallons.
1 cubic foot of water weighs 62.5 pounds.
1 foot per second equals 0.682 miles per hour.
1 horse-power equals 550 foot pounds per second.
1 horse-power equals 746 watts.
1 horse-power equals 1 second-foot falling 8.80 feet.

To calculate water power quickly: $\frac{\text{Sec.-ft.} \times \text{fall in feet}}{11}$ = net horse-power on water wheel, realizing 80 per cent. of theoretical power.

Methods of Measuring Stream Flow.—There are three distinct methods of determining the surface flow of streams: (1) By measurements of slope and cross-section and the use of Chezy's and Kutter's formulae; (2) by means of weirs, which include any device or structure that by measuring the depth on a crest or sill of known length and form, the

flow of water may be determined; (3) by measuring the velocity of the current and the cross-section. This third method is the one most commonly used by this survey. The second is used when the flow is too small to be accurately determined by the third, while the first is only used in making estimates of the discharge of a stream when the only data available are the cross-section and slope.

Slope Method of Determining Discharge.—The slope of a stream, or rather of a section of a stream, is the difference in elevation between the upper and lower ends of the section, commonly called the fall, divided by the distance or the length of the section. Slope sections vary in length from two or three hundred feet to several hundred feet, depending largely upon the nature of the stream.

It is difficult to ascertain accurately the slope of the water surface in a stream, since in nearly all streams there are pulsations in the water, causing the surface to rise and fall locally. In most streams the slope of the bottom is far from uniform, and the flow of water in any given section is more or less influenced by the flow in the adjacent section, above or below. For this reason it is a good plan to consider a number of adjacent sections, comprising a considerable length of the stream in one computation, being careful to take into account the diversity of cross-section at various places in the length.

In determining the slope of the surface of a stream, levels are taken of the water surface at each end of the slope section, and referred to some datum or bench mark. A good plan is to set firmly a stout wooden stake below the water surface at each end of the slope section, and then to drive a nail into the top of each stake, so that the nail-head will exactly coincide with the water surface. The difference in elevation between the two nail-heads, divided by the distance between the stakes, will give the slope.

The wetted perimeter is that portion of a stream channel that is in contact with the water. The form or outline of the wetted perimeter of a stream has an important influence upon the velocity of the current. It is usually determined graphically from the plotted cross-section or may be measured by means of a flexible tape or chain after the flood has subsided.

The hydraulic radius, which is sometimes called the mean radius of the channel below the water surface is found by dividing the area of the cross-section (in sq. ft.) by the length of the wetted perimeter (in feet).

The Chezy formula, which is the fundamental formula for stream discharge, is:

$$Q = A\,V$$

in which Q = the discharge of the stream in sec. ft.
A = the area of the cross-section in sq. ft.
V = the mean velocity of flow, in ft. per sec.

In applying this formula to the determination of stream discharge, the mean velocity of a stream is considered a function of the slope and one of the wetted perimeter of the stream. This may be expressed by formula as follows:

$$V = C\sqrt{r\,s}$$

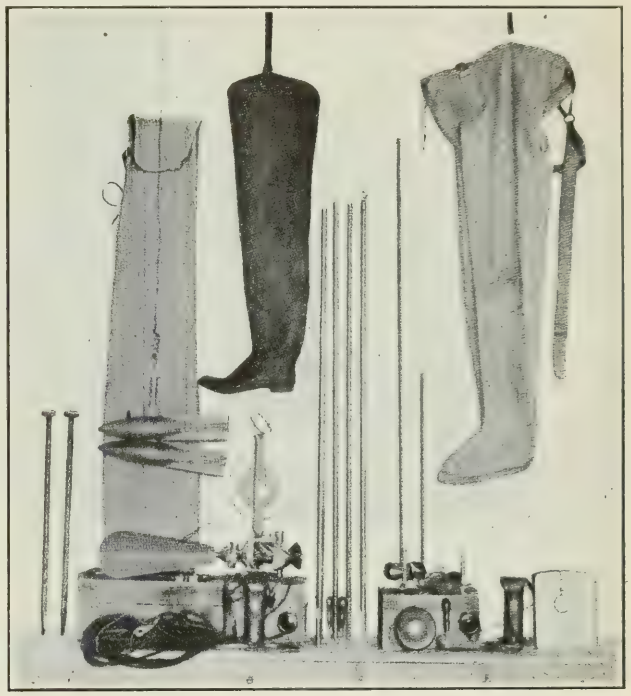
in which r = the hydraulic radius of the channel.
s = the surface slope.
and C is a variable coefficient, depending upon the nature of the channel.

In determining the value of C for any given case it is customary to make use of Kutter's formula, which is:—

$$C = \frac{41.6 + \dfrac{.00281}{s} + \dfrac{1.811}{n}}{1 + \left(41.6 + \dfrac{.00281}{s}\right)\dfrac{n}{\sqrt{r}}}$$

In this formula r and s have the same significance as in the Chezy formula and the new factor n is called the coefficient of roughness. It is a variable coefficient, and its value is dependent upon the size, shape, slope and degree of roughness of the channel. Tables of values of n are given in various text books, but it is difficult to choose the correct value. It is therefore advisable whenever possible to compute the value of n from a measured discharge. As the slope method of determining discharge is seldom employed except to estimate flood discharge, a current meter measurement is very often made at the slope section, during low water. Having determined the mean velocity, slope and hydraulic radius at the time of the metering, the value of C may be found from the formula $V = C\sqrt{rs}$ or $C = \dfrac{V}{\sqrt{rs}}$.

Trautwine's Pocket Book for Civil Engineers and other texts contain tables giving the value of n for different values of



Meters and Equipment for Measuring the Discharge of a Stream by the Velocity of Method.

r, s, and c. From these tables we can interpolate the proper value of n for a particular section of the stream, at low water stage. In most cases this value of n is applicable to high water and flood conditions of the stream also and is used with values of r and s for the high water or flood cross-section to determine the value of C at the higher stage. Having determined the value of C the computation of the discharge is simple.

The results obtained by the slope method are in general only roughly approximate, owing to the difficulty in obtaining accurate data and the uncertainty of the value of n to be used.

Weir Methods of Determining Discharge.—As yet no permanent weirs have been constructed by this survey, and the only regular weir measurements have been on small streams by means of a temporary weir. The weir used consists of a wooden base of 2-inch plank, to which is bolted

a rectangular notch of three-eighths inch steel with bevelled edges.

In making a measurement by means of a temporary weir, the following directions should be followed as far as possible. The weir should be placed perpendicular and at right angles to the bed of the stream with the crest level. The discharge should be free in so much as the nappe should have sufficient fall to allow air to have free circulation underneath it, and the head or depth on the crest should not exceed one-third of the length. The channel of approach should be several times as wide as the opening and the depth of water in the bay or pond should be at least twice the head on the weir, so as to eliminate velocity of approach and cross-currents. In choosing a site for a weir, a point should be chosen that will fulfil the above conditions and give a good sized bay or pond.

To set up a temporary weir, a dam of sods and earth are thrown across the stream, the weir set in place and the sods tramped firmly around it to stop all leakage. On a stream with a sandy bed sods or clay must be placed on the bottom for a few feet upstream to form a mattress to prevent the undermining of the dam.

After the bay has filled up the head of the water is observed by taking the difference in elevation of the crest of the weir and the elevation of the water surface in the bay at a distance of 4 to 10 feet from the weir, with an engineer's level. Two common methods of getting the elevation of the water surface are (1) hold the levelling rod on a stone or other body under water and subtract the depth of water on the rod from the sight on the rod; (2) drive a pin divided into tenths of feet into the bed of the stream so that an even tenth is level with the surface of the water, then hold the levelling rod on the top of the pin and add the length of pin above the water to the sight on the rod.

When the head of water has been determined, the discharge is computed by using one of the standard formulae which will suit the case. Tables giving the discharges for different heads and lengths of crests are published in many engineering texts.

The formula used by this survey for rectangular sharp-crested weirs is:

$Q = 3.33\ (L - .2H)\ H3/2$ being a modification of Francis' formula, to allow for end contractions and elimination of velocity of approach.

in which Q = discharge in sec. ft.; L = length of crest in feet; H = head in feet.

Measurements by means of temporary weirs should be made some distance above or below the gauge. If they are made close to a gauge, the gauge must be read before the weir is placed in the stream and the pond must be allowed to run off after the weir is removed before the gauge is re-read.

Velocity Method of Determining Discharge.—There are two methods of determining the velocity of flow of a stream, namely, direct and indirect. In the direct method by which the velocity is determined by means of floats, the liability of error is large, and the results far from satisfactory. This method is seldom used except for very rough estimates or when a current meter cannot be used. There are three common kinds of floats, viz.: surface, sub-surface and tube or rod floats. In each the procedure in the same. A straight piece of channel is selected for the run and two cross-sections taken at some convenient distance apart. usually from 100 to 200 feet. They are then divided into strips by means of a tagged wire. The velocity in each strip is then measured by noting the time taken by the float in traversing the run or distance between the two cross-sections. As the time and distance are both known the velocity can easily be computed. The velocity, whether measured by surface, sub-surface or tube floats, must be multiplied by a coefficient less than unity to reduce the mean velocity before being used to compute the discharge.

The indirect or current meter method is the most reliable and most widely used method of determining the velocity of the flow of a stream. The meter used by this survey is the Price Patent, manufactured by W. & L. E. Gurley. Troy, N.Y. It consists of six cups attached to a vertical shaft which revolves on a conical hardened steel point when immersed in moving water. The number of revolutions is indicated electrically. The rating or relation between the velocity of the moving water and the revolutions of the wheel is determined for each meter by drawing it through still water for a given distance at different speeds and noting the number of revolutions for each run. From this data a rating table is prepared which gives the velocity per second of moving water for any number of revolutions in a given time interval.

The accuracy of a discharge measurement taken at a velocity-area station is dependent on two factors. the accuracy with which the area of the cross-section and the mean velocity of the flow normal to that section are measured. There is no special difficulty in measuring the first factor, but the second, the velocity, is very difficult to measure accurately, because it is constantly changing. It varies not only from the surface to the bottom but from one bank of the stream to the other, making it necessary to measure it at a number of points.

In making a measurement with a current meter, a number of points, called measuring points, are measured off above and in the plane of the measuring section, at which observations of depth and velocity are taken. These points are spaced equally for those parts of the section where the flow is uniform and smooth, but should be spaced unequally for other parts according to the discretion and judgment of the engineer. In general, the points should not be spaced farther apart than 5 per cent. of the distance between piers, nor farther apart than the approximate mean depth of the section at the time of measurement.

The measuring points divide the total cross-section into elementary strips at each end of which observations of depth and velocity are made. The discharge of any elementary strip is the product of the average of the depths at the ends, the width of the strip, and the average of the mean velocities at the two ends of the strip. The sum of the discharges of the elementary strips is the total discharge of the stream.

Methods of Determining Mean Velocity.—There are a number of different methods of determining the mean velocity at the ends of these strips, or, as it is commonly called, the mean velocity in a vertical, namely, multiple-point, single-point, and integration. These three principal multiple-point methods in general use are the vertical velocity-curve, three point, and two point method.

Vertical Velocity Curve Method of Determining Mean Velocity.—In this method the centre of the meter is held as close to the surface of the water as is possible, being careful to keep it out of reach of all surface disturbances, and then at a number of different depths throughout the vertical. The velocity at each position of the meter is recorded. These observations are then plotted with velocities in feet per second as abscissae and their corresponding depths in feet as ordinates and a mean curve is drawn through the points. The mean velocity for the vertical is obtained by dividing the area bounded by the curve and its axis by the depth. In the absence of a planimeter for measuring the area, the depth is divided into 5 to 10 equal parts, and the velocities of the centre ordinates of these parts are noted. The mean

of these velocities will very closely approximate the mean in the vertical.

It is often more convenient, when the depth is a number of feet and a fraction, as 7.4, to divide the depth into 7 parts of a foot width, and a part of 0.4 foot width. Then the velocity to enter for the narrow part is 0.4 of the velocity at the centre of it.

The vertical velocity curve is useful in studying the manner in which velocities occur in a vertical. From a study of a number of these curves the other shorter methods of determining mean velocity are deduced. This method is not used in general routine measurements, except during the winter, on account of the length of time taken to complete a measurement, for a change of stage is almost sure to occur during a measurement on a large stream which counterbalances the increased accuracy. For this reason its use is limited to the determination of the coefficient to be used in the reduction of values obtained by other methods of measuring velocity to the true value, to the measurement of velocities under new and unusual conditions of flow, and for measurements under ice.

Three-Point Method of Determining Mean Velocity.—This method gives the greatest accuracy outside of the vertical velocity curve and is the method most commonly used by this survey during the open season. The meter is held at 0.2, 0.6 and 0.8 depth. The mean velocity is then obtained by dividing by 4 the sum of the velocities at 0.2 and 0.8 depth plus twice the velocity at 0.6 depth. It is the best method to use during low water or in wide shallow streams having a rough bed where the thread of mean velocity varies considerably from the 0.6 depth.

Two-Point Method of Determining Mean Velocity.—In studying the vertical curves made at a number of different points and under varied conditions it has been found that the mean of the velocities occurring at 0.2 and 0.8 depths gives very nearly the mean velocity in the vertical. Use is made of this fact in the two-point method of determining mean velocity, the meter being held at 0.2 and 0.8 depth in the vertical. This method has been found more accurate than the single point method and the time required for a metering is not very much greater. This method has been found to give, also, a very close approximate to the mean velocity in measurements of ice-covered streams, although these flow under very different conditions from those of open water.

Single-Point Method of Determining Mean Velocity.—Experiments made under most favorable conditions and extending over a long period have established the point of mean velocity in a vertical at 0.6 of the depth. Therefore the error resulting from the use of the 0.6 depth as the depth of mean velocity is very small though in some few cases a study of the vertical velocity curve will show the need of a coefficient to reduce the observed velocities to the mean. The variation of the coefficient from unity in individual cases is, however, greater than the two or three point method and the general results are not as satisfactory. For that reason this method is not employed very extensively by the survey.

In the other principal single-point method the meter is held near the surface, at from 0.5 to 1 foot below the surface; care being taken to sink the instrument below the influence of wind or waves. The resulting velocities must be multiplied by a coefficient to reduce them to mean velocities. This coefficient as found by a large number of experiments, varies from 0.78 to 0.98, depending upon the depth and speed of the stream. The deeper the stream and the greater the velocity the larger the coefficient. In flood work coefficients varying from 0.90 to 0.95 should be used. This method is only used when the current is too strong to permit the sinking of the meter to any great depth below the surface of the water. It is often employed at times of flood, or when a stream is carrying a lot of drift wood or ice.

Integration Method of Determining Mean Velocity.—This method of determining the mean velocity in a vertical consists in moving the meter at a slow uniform speed from the bed of the stream to the surface and return in a vertical direction, the time and revolutions being observed. In travelling through all parts of the vertical the meter is acted upon by each and every thread of velocity from the bed to the surface of the stream, and the resulting observations determine the mean in that vertical.

This method is very useful in checking the results of other methods. It is, however, seldom used by this survey as the Price meter is not suited to observations by this method, since the vertical motion of the meter causes the wheel to revolve.

Gauging Stations.—The first step is to select a suitable locality for a gauging station. Although apparently simple, this is really a difficult task. Not only must the water be moving in nearly straight lines over a solid bed and between well defined banks, but the place must be accessible at

Measuring the Velocity with a Current Meter by Wading.

moderate cost and there must be living near a competent person who can be engaged to serve as observer. Permanent gauging stations should only be selected after a very thorough reconnaissance. In the irrigation districts and in more thickly populated districts there is more or less diversion of water. This is apt to complicate matters for the hydrographer, or a gauging station above all works may not include all the tributaries of the stream and it is often necessary to establish gauging stations at several points along the streams, and on tributaries, canals and pipe lines, in order to obtain complete information regarding the water supply in a particular stream.

There are three classes of gauging stations, namely, wading, bridge and cable stations. The wading station can, of course, only be used in the case of small streams having a maximum depth at its highest stage of 3 feet or less. The equipment for a wading station is small, consisting usually of a plain staff gauge, graduated to feet and hundredths, and fixed vertically to one of the banks of the stream. For convenience a measuring line, usually a wire with tags, may be fixed permanently at this section. When taking the reading, the hydrographer should stand below and to one side of the meter so as to not cause eddies in the water.

Bridge stations, because of their permanency and the freedom of movement allowed the hydrographer, are much preferred. Very often, however, more particularly in swift

currents, the piers materially affect the accuracy of the results. When the gauge cannot be attached to a pier, it is often attached horizontally to the guard-rail or floor of the bridge and the height of the stream is found by lowering a weight by a chain over a pulley. It is indicated by a marker on the chain. Distances of three, five or ten feet according to the size of the stream are marked on the lower chord of the down stream side of the bridge, to serve as a measuring line.

Frequently it is impossible to establish a permanent gauging station at a bridge. In that case the wire cable of a ferry can be utilized, or, if that is not available, a permanent wire cable is stretched across the river. For spans of average length a galvanized wire cable three-fourths of an inch in diameter is safe. It is supported at each bank by means of high struts or by passing it through the crotch of a tree. The cable is run into the ground and anchored securely to a "dead man" buried at least six feet below the surface, or, if convenient, it is anchored to the lower part of the trunk of a tree. A turnbuckle is inserted in the cable between the strut and anchorage to permit tightening the cable when it begins to sag. A permanent measuring line, usually a wire with tags 5 or 10 feet apart, is stretched across the stream just above the cable. A cage large enough to carry two men and instruments is constructed and suspended from the cable by means of cast iron pulleys. The cage is moved from point to point by hand. A stay line, usually quarter-inch guy wire, is stretched across the stream about thirty to forty feet upstream from the cable, and securely fastened. By passing a sash cord through a pulley hung on this stay line the current meter is prevented from being carried down stream.

Low Velocity Limitations.—Owing to the presence of a slight amount of friction in the current meter, a certain definite velocity is required to make the wheel revolve, i.e., to overcome the frictional resistance of the wheel. For this reason the meter is unsuitable for the measurement of low velocities, approaching this value. This velocity, which is required to overcome friction, and which is obtained from the meter rating curve, is called the velocity of no flow for the particular meter referred to. It varies in different types of meters, and also slightly in meters of the same type, according to the time the meter is in use, but very seldom exceeds 0.2 foot per second in any meter. From a number of observations the low velocity limit, below which values of velocity are unreliable, is found to be 0.5 foot per second. In many cases at low stages the gauging station on a stream becomes unsuitable for a discharge measurement owing to the mean velocity in the section falling below the safe limit. In such instances where it is possible to wade the stream a suitable gauging section may be located within a reasonable distance of the regular station and the discharge measurements made at this point. When a gauging is made at a cross-section other than the regular station, sufficient soundings should be made at the latter at the time of the gauging to develope the cross-section and compute the area. The measurement is thus referred to the regular gauging station and the mean velocity and area at the regular section is reported and used in the office computations.

Winter Measurements.—Previous to the season of 1910-11, no records were taken of the flow. During the past winter daily gauge height records were collected for a number of the more important streams in the Calgary and Macleod districts. Discharge measurements were made at these stations at intervals of from two to three weeks.

The laws governing the flow of stream in open channels have, through extensive investigations, become well defined, but the flow under an ice cover has been but little investigated. In winter as in summer the daily discharge of a stream is computed from frequent discharge measurements and daily gauge height observations. In most cases, however, the vertical, velocity curve method is used for the determination of the mean velocity in the vertical, as the mean velocity varies considerably. In fact, there are usually two points in the vertical at which the thread of mean velocity occurs under an ice cover. These points are near 0.2 and 0.8 depths and two-point method will give fairly accurate results, but in this report all discharges are based on computations from vertical velocity curves.

The discharge measurements are made through holes in the ice from 5 to 10 feet apart, and large enough to allow the meter to pass through freely. The measurement is then taken in the same manner as at open sections, except that the depth of the stream is taken as the distance from the bottom of the ice to the bed of the stream. The soundings, however, are always referred to the surface of the water in the holes, the distance from the surface of the water to the bottom of the ice being measured and subtracted from the sounding to obtain the depth. The meter should be kept in the water continuously to prevent the wheel from freezing and sticking.

The gauge is read once a day, the observer noting the elevation of the water as it rises in a hole cut through the ice, the height of the top of the ice, the thickness of the ice, presence of needle or slush ice, snow on top of ice, ice jams, and also any sudden changes in temperature. To do this observers are provided with an ice chisel for chopping holes, and a square to measure the thickness of the ice. Any form of gauge may be used but the chain gauge is the most satisfactory, as the staff gauge being frozen to the ice, heaves with it.

Some of the cross-sections used in the summer were found to be unsuitable for winter measurements. This was usually caused by the cross-section filling up with slush, needle or anchor ice. There is a flow through this ice and it is impossible to measure it. The most suitable stations for winter measurements are those where there is a long stretch of very smooth sluggish water above the station and a rapid fall below.

Re-Rating of Current Meters.—Each meter is rated before being used, in order to determine the relation between the revolutions of the wheel and the velocity of the water. The meter is driven at a uniform rate of speed through still water for a given distance, and the number of revolutions of the wheel and the time are recorded. From this data the number of revolutions per second and the corresponding velocity per second is computed. Tests are made for speeds varying from the slowest which will cause the wheel to revolve to several feet per second. The results of these runs, when plotted with revolutions per second as abscissae and velocity in feet per second as ordinates, locate points that define the meter rating-curve, which for all meters is practically a straight line. From this curve a meter rating table is prepared. Theoretically, the rating for all meters of the same make and type should be the same, but as a result of slight variations in construction, and in bearing of the wheel on the axis at different velocities, the ratings differ. After a meter has been in use for some time the cups may have received small injuries, or the bearing of the wheel on the axis may have changed owing to unavoidable rough usage. These changes will affect the running of the meter and change its rating. As a consequence each meter is re-rated at regular intervals and a new rating curve and table prepared. During 1910 several meters were re-rated by F. H. Peters by means of a gasoline launch on Chestermere Lake, and with only one excetion the meters varied but little from the original rating.

The boat method of rating meters is, however, very crude, and Mr. Peters has designed an up-to-date rating station consisting of a concrete lined tank, 250 feet long, 6 feet wide, and 5½ feet deep, and a car operated by a motor. This will be constructed at once and all the meters will be carefully re-rated at regular intervals.

Office Computations.—Rating Curves and Tables.—When a series of discharge measurements has been made at a gauging station a rating curve is constructed for that station, showing graphically the discharge corresponding to any stage of the stream within the limits covered by the gaugings. This curve, as it is usually drawn, has an abscissae, the discharges in second-feet and as ordinates, the corresponding gauge heights at which the discharges were made. A smooth curve is drawn through the resulting set of points and from this curve the discharges at any stage within the limits of the curve are taken. Some measurements may be more reliable than others owing to more or less favorable conditions at different times of gauging, or to other causes. In order to obtain the weight of the different measurements, curves with area and mean velocity, as abscissae, and gauge heights as ordinates, are also drawn. From a study of these curves any discrepancies in a measurement, either in its area or mean velocity, may be detected. Should it be necessary to extend the rating curve beyond the limits of actual discharge measurements the area and mean velocity curves may be constructed to the stages for which the discharge curve is desired and the latter found by taking the product of the two curves. The discharge curve under natural conditions of flow is always convex to the gauge height axis. The area curve is either a straight line or is convex to the gauge height axis, except in the case of overhanging banks when it becomes concave to the axis. This mean velocity curve is always concave to the gauge height axis, except in cases where standing water occurs below the stage of no-flow. In this case the curve will assume a reverse form, starting from the gauge height of zero flow with a curve convex to the gauge height axis and gradually reversing to a curve concave to this axis. In plotting all three curves the horizontal and vertical scales should be so chosen that the curves may be used within the limits of accuracy for the work, and in their critical position will make, as nearly as possible, angles of 45 degrees with each axis.

The rating curve being constructed, it becomes necessary to prepare a station rating table, giving the discharge at any stage of the stream within the limits of the daily gauge height observations on record. From this rating table the daily discharges corresponding to the daily gauge heights are read and tabulated. The rating table is constructed for tenths, half-tenths, or hundredths of feet, according to the readings of the gauge to which it is to be applied. The discharges for this table are read directly from the rating curve and are then adjusted so that the differences for successive stages shall be either constant or gradually increasing, but never decreasing, unless the station is affected by backwater.

Daily Discharge, Monthly Mean, and Run-Off.—The rating table being made to cover the range of daily gauge height observations, the next procedure in the computations is to make out a table of daily discharges from this rating table. The daily gauge heights are copied as they were sent in by the observer and opposite each the corresponding discharge is filled in from the rating table. The monthly discharge is found by totalling the daily discharges for the month in question and the monthly mean is obtained by dividing this total by the number of days in the month.

The run-off is computed with two different sets of units, depending upon the kind of work for which the data is intended, as follows: (1) Run-off in inches is the depth to which a plane surface equal in extent to the drainage area would be covered if all the water flowing from it in a given time were conserved and uniformly distributed thereon; it is used for comparing run-off with rain-fall, which is usually expressed in depth in inches. The mean run-off in second-feet per square mile for each month is used. The monthly mean run-off in second-feet is divided by the area of the drainage basin in square miles to find the monthly mean run-off per square mile. This result, reduced to run-off in depth in inches for the monthly period, is in the form required.

(2) The run-off in acre-feet is the form of most use in connection with storage. An acre-foot is equivalent to 43,560 cubic feet, and is the quantity of water required to cover an acre to the depth of one-foot. The monthly mean run-off in second-feet is used for the computation of run-off in acre-feet. The monthly mean is reduced to cubic feet per month and this quantity divided by 43,560 gives the run-off in acre-feet.

Thirty-Six-Inch Sharp Crested Rectangular Weir Used on Small Streams.

The run-off of the stream being computed both in depth, in inches and in acre-feet for each month, the run-off for the period, during which observations of run-off were made, is found by the summation of the amounts of run-off for the several months making up this period.

Changing Conditions of Channel.—On streams such as Milk River, whose bed is in a constant state of motion, measurements of discharge should be made every few days, otherwise considerable data relating to changes cannot be obtained. For discharges on days other than those on which measurements are taken, the interpolation method is used. The two methods of interpolation in general use are the Stout and Bolster Methods.

The Stout method deals with the correction of the gauge heights. A curve is drawn, using the difference between the actual gauge heights at the time of measurement and the gauge height corresponding to the measured discharge as ordinates and the corresponding days of the month as abscissae. From an irregular curve drawn through these points corrections for gauge heights can be made for days on which there was no discharge measurement. When the

discharge is greater than that given by the curve the correction is positive and vice-versa. Each daily gauge height is corrected by the amount shown on the correction curve, and the corresponding discharge taken from an approximate rating curve for the station.

The Bolster method deals more particularly with the modification of the discharge. Results of discharge measurements covering a whole year or season are plotted, and though considerably scattered, will define one or more regular curves, called standard curves, the number and position of each indicating the radical changes. Where the river bed changes from day to day, the position of the standard curve also varies and must pass through the points indicating the different days. The points indicating two successive measurements are joined by a line, which for short distances on the cross-section paper is a straight line and otherwise a curve. This line is divided into a number of equal parts, each indicating an intervening day, the assumption being that as the change during this period is gradual the daily rating must pass through each point, or day, as represented by the divisions. A simple and convenient way of making these interpolations and moving the daily rating curve is to make a tracing of the standard curve with a vertical line of reference. By keeping the lines of reference coincident this curve can be shifted into any desired position and the discharge read for any gauge height.

PUMPING TERMS.

A number of different terms are used in connection with pumping, and very often it is hard to determine just what is meant by certain designations. The accompanying dia-

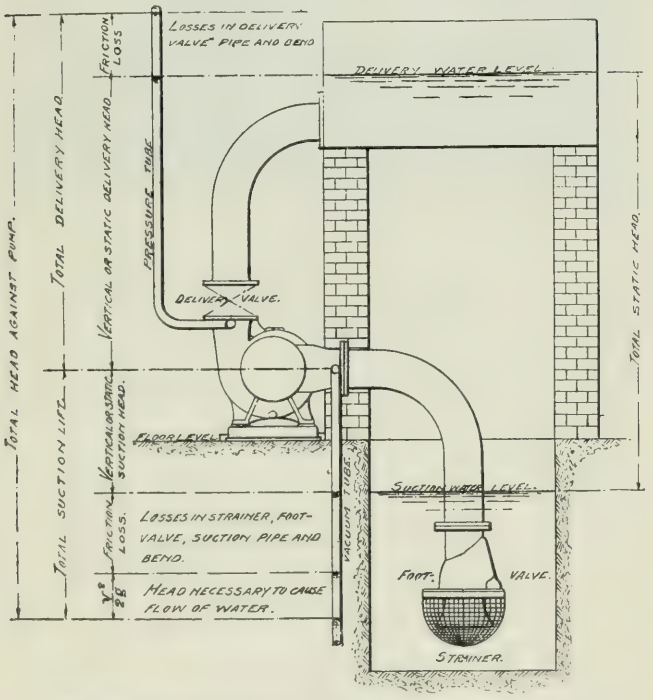


Diagram illustrating the Terms generally used in connection with Pumping.

gram, reproduced through the courtesy of Drysdale & Co., Limited, Yoker, Glasgow, W., from a pamphlet issued by them, shows graphically and clearly the meaning of the different terms.

AUXILIARY PLANT FOR POWER STATIONS.

By A. H. Finch, M.A.

(Continued from last issue.)

Auxiliaries as Labor-Saving Devices.—We now come to another class, or sub-division, of auxiliaries; those, that is, which are in reality, only substitutes for labor. It is here that a temptation towards multiplication is so often evident. Certain of them, however, are so obviously superior to the intermittent or collectively large amount or labor which they displace that there is usually no question as to the advisability of adopting them; such are water-service pumps and coal-handling machinery, cranes, and bilge pumps. In the case of cranes, it is the ability to concentrate the requisite power into a small space that is valuable; with coal-handling machinery it is advantageous in any event to use some form of mechanical lifting appliance, and the question of applicability of the power settles at once the method of driving.

Stokers.—No such argument applies to mechanical stokers. Here the question is between an expensive appliance, capable of giving smokeless combustion and better efficiency due to absence of frequently-opened doors and more even distribution of fuel, and a cheap arrangement involving a larger amount of labor and producing poor combustion at times. No comparison in an exact sense is possible, for the reason that the conditions prevailing in any given station—such as load factor or number of shifts worked—will radically influence the figures.

The following illustration is intended to apply to a boiler house running on a load factor of about 60 per cent. with three equal shifts, capacity 8,000 kw. The capital costs are taken to be:—

For mechanical stokers, shafting, motors, and wiring, and dumping gear	£3,460
For fire-bars and furnace fronts adapted to hand firing	320

Capital charges taken at 15 per cent. Maintenance charges on mechanical stoker gear, at 10 per cent., and on hand-firing apparatus, due to wastage of fire-bars, at 80 per cent.:—

Mechanical firing—	
Capital charges	$ 519
Maintenance	346
Power, say 16 kw. for 4,600 hours per annum at 0.25d.	77
Labor, 3 shifts at 125s. per week per shift	975
	£1,917
Hand firing—	
Capital charges	48
Maintenance	256
Labor, 3 shifts at 245s. per week per shift	1,910
	£2,214

In this instance there is apparently a balance of £300 in favor of mechanical stokers, making out a fairly obvious case. If, however, no night shift (in the ordinary sense) is worked, the necessary night attendance, if any, being in both cases the same, the mechanical arrangement is reduced to £1,592, and the hand firing to £1,577, and in such a case a more careful inquiry into the actual figures for maintenance, cost of power, etc., obtained in practice might point to adopting hand firing in spite of the better combustion obtained with the alternative method. Or, again, if we con-

sider the case of an installation where native labor is available, the account for a 3-shift load might stand as under:—

Mechanical stoker—	
Capital charges as before	£ 519
Maintenance as before	346
Power as before	77
Labor, 3 shifts at £104 per shift per annum, being composed of twice the number of men assumed in the previous example, but at something like one-sixth the rate	312
	£1,254
Hand firing—	
Capital charges	£ 48
Maintenance	256
Labor, 3 shifts at £200 per shift per annum	600
	£904

showing a substantial advantage in hand firing.

Clearly, then, the labor conditions and the nature of the load are weighty factors in settling such a point. In fairness to the stoker method, it must be pointed out that better combustion generally results from its use, and inferior coals can be successfully burned. On the other hand, the method of hand firing offers greater flexibility and enables a wide variety of coals (as regards their components) to be used. Hence it is that no exact comparison is possible without details being in every case considered; while a further factor is the limitation imposed by the length of grates where very large hand fired boilers are involved. In such cases the necessary grate area can only be obtained by increasing the width of boiler, which may lead to structural difficulties and an abnormal amount of floor space.

Ash Handling.—Another item in which the labor question is a prominent feature is ash handling. Owing to the nature of the material, all mechanical apparatus, except of the simplest character, is a source of excessive maintenance costs. On the other hand, the conditions under which ashes have to be handled make it difficult to obtain labor at a reasonable rate. Where tunnels are used they are often unbearably hot, or, being situated below everything else, and liable to choked drains, they readily become flooded. Large quantities of dust are produced in the process of handling, and if quenching or spraying is resorted to, this results in the formation of active corrosive agents.

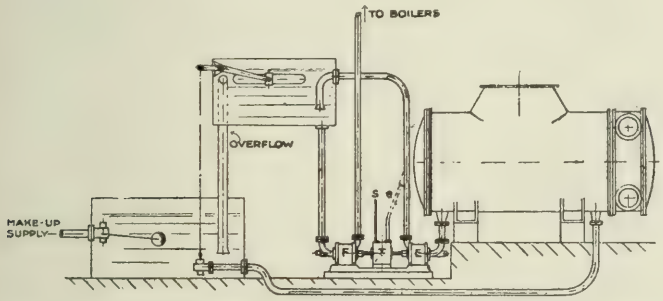

Fig. 1.—Diagrammatic Arrangement of Proposed Closed-Cycle System of Boiler Feeding.

E = Extract on Pump. F = Feed Pump. T = Auxiliary Turbine. S = Steam to Auxiliary Turbine. e = Exhaust from Auxiliary Turbine.

Systems have been developed in which air or water is the conveying agent, and these have the advantage over any mechanical system in that the handling involved is a minimum, and no moving machinery is required except a pump, which can be placed out of reach of damage from the dust, and a breaker or crusher. With this arrangement there is necessarily considerable wear on the tubes or channels which convey the ashes; but such parts are cheaply replaced. The drawback of the system, from the point of view we are now considering, is that it introduces two auxiliaries, viz., the crusher and pump; but the former can be a very robust piece of apparatus. The channels for conveyance of ashes can be brought close up to each boiler, and by using suitable means for introducing them into the crusher or channels, dust can be effectually confined.

Where the conditions of manual operation are so unfavorable, there is a strong case for mechanical handling, but the choice of apparatus should fall on that which can be made of the stoutest construction, a consideration which would operate against conveyors, elevators, or hoists of the usual description.

Switches.—The working of switches is a question wherein ease of manipulation from a distance is the paramount consideration. To bring the control of a large number of switches into any convenient compass can, it is true, be accomplished in the same way as with railway signals and points, by a system of levers and rods; but this system is being replaced on important signal installations by electricity, either alone or in combination with compressed air. In a power station where electrical manipulation is unaccompanied by exposure of apparatus to the rough conditions of a railway track, it is obviously indicated in preference to a purely manual process for control of a large number of switches, failure of the current being a remote contingency owing to the invariable practice of employing a battery.

There remains for consideration a class of casual services whereon motors are often employed, such as water softeners, weighbridges, air compressors, and boiler-cleaning pumps. The general principle applicable to such cases is that the extent of use should settle the method of driving. To take the cases cited; the softener may be used continuously, and so require regular attendance, or intermittently, being idle for weeks. In the former cases power operation is justified, in the latter, not; unless, owing to great size, manual labor cannot be advantageously employed. Weighbridges of a type in which a motor is necessary to move counterweights or raise the table only justify themselves by frequency of use. Air compressors, universally used for cleaning electrical apparatus, are a necessity in a large power station, but a luxury in a small sub-station where bellows will do the work; and boiler-cleaning pumps (for use with water-tube boilers) become necessary where the frequency of use is such that a boiler feed pump cannot be spared for the purpose, or where soft water is used for cleaning and the risk of getting it into the boilers cannot be run.

Certain auxiliaries are to be found associated with the purely electrical portion of a station, which do not fall exactly into either of the two arbitrary divisions that have been discussed. Such are fans for ventilating electrical apparatus whether rotating or stationary. The measure of the value of these is, in general, the degree to which they increase the capacity of a given weight of copper or iron in electrical apparatus. With rotating plant, the alternative is ventilation by what really amounts to a fan on the rotating portion of the generator itself; and as the rotating of this portion in most designs is necessarily accompanied by some fan action, it would appear a logical extension of the principal to make the rotor do the whole work of ventilation, the slight additional power requiring no increase in the shaft or bearings. Clearly, then, an auxiliary fan is not justified in this case, unless the conditions are such (for in-

stance) that air has to be brought to the generator from a distance in an enclosed duct, the friction of which, unless it be unduly bulky, might result in an insufficient supply; or where air filters are necessary; or, in similar circumstances, when the resistance to be overcome is greater than can be dealt with by a rotor fan whose speed and diameter are fixed by those of the generator.

With non-rotary apparatus, such as transformers, the method of direct ventilation by air finds an alternative in cooling by oil, or water. Oil is of necessity the immediate cooling agent of the metal. It is practicable to cool the oil either by water-pipes within the transformer case, or by passing it through an external cooler, wherein water is circulated. Where a supply of water exists under sufficient head, a water pump is not necessary; but an oil pump is introduced with the method of external cooling. This is against the method; its advantage lies in more effective cooling and a reduction in the risk of leakage of water into the oil, which can be accomplished by giving the oil within the cooler a higher pressure than the water. Any system of water cooling has the advantage over the usual methods of fan cooling that the heat abstracted is not liberated within buildings; more important perhaps in tropical climates than in these latitudes.

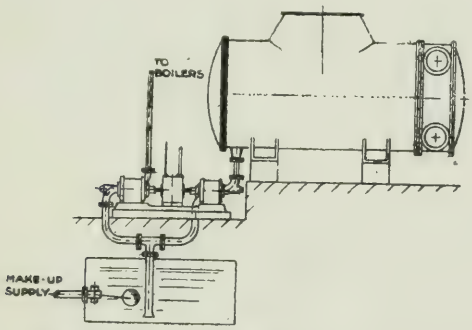

Fig. 2.—Diagrammatic Arrangement of an Alternative Closed-Cycle System of Boiler Feeding.

Exciters almost claim a place for themselves, particularly since so much attention has always been devoted to the subject. As between the independently-driven machine, and one directly coupled to the shaft of the alternator it is intended to excite, the arguments may be grouped thus:—

Against the direct coupled exciter—(1) Small size and inefficiency. (2) In turbine stations, addition to length of whole unit which may require a wider engine-house. (3) Cumulative effect on bus-bar pressure of a fall in speed. (4) Inability to be used for station lighting, etc.

Against the independent exciter—(1) Cost of separate engine or motor (usually the former) to drive it. (2) Cost of running the same, including maintenance and ultimate coal consumption. (3) Duplication.

Given sufficiently good voltage regulation, the method of direct-coupled exciter, even if accompanied by motor generators for battery charging or station lighting, produces a simpler total combination and one more easily kept in an efficient state of repair.

Methods of Driving Auxiliaries.—Three systems are in vogue, viz., electricity, steam (for certain limited services) compressed air. The last is the least efficient, but has the merit (where a reservoir is provided) of being to some extent independent of failure of the main supply.* For an infrequent service such as valve operation, economy ceases to be of importance, and the use of air may be justified by cheapness of the actual engine and piping employed in comparison with an electric motor and wiring. On the other hand, an independent source of power, viz., air compressor, is necessary, whereas auxiliary current at most requires only a transformer. On general grounds, since a power station must employ steam and generate electricity, it would seem preferable to use one of those agencies rather than air, which requires additional apparatus and only introduces an indirectness in the application of power.

*Employed for this reason in actuating the brakes on some form of electrical winding gear for collieries.

Steam v. Electricity.—As between steam and electricity, the principle suggested is that steam should only be used where it introduces a simplification, not so much in respect of economy as by offering a simpler combination of apparatus. This is said with particular reference to the use of exhaust steam for feed heating. Where the exhaust cannot be so used, either wastefulness is introduced by exhausting to atmosphere, or complication ensues from the addition of an auxiliary condenser, and possibly an oil separator, to the total of auxiliary plant.

Let us examine the case of a direct-acting feed pump working without lubrication. It consumes anything between 65 and 100 lbs. steam per water horsepower per hour, say 75 lbs.; whatever the pressure at release, in round numbers the exhaust carries away 1,200 B.T.U. (reckoned from 0 deg. F.) per lb. To fix the ideas, consider a 1,000-kw. turbine, using 18,000 lbs. steam per hour. With boiler pressure 175 lbs. per square inch, the water h.p. is 3.58, and the pump steam per hour $= 3.58 \times 75 = 268$ lbs. Therefore the heat available for feed heating is $268 \times 1{,}200$, or say 320,000 B.T.U. If the initial temperature of the feed be 90 deg. F. (28 in. vacuum corresponds to 101 deg. F.) each pound contains 90 B.T.U. reckoned from zero, and the whole feed contains $18{,}000 \times 90$, or 1,620,000 B.T.U. The final temperature therefore becomes—

$$\frac{1{,}620{,}000 + 320{,}000}{18{,}268} \text{ or } 100 \text{ deg. F.}$$

In this case, an expenditure of $\frac{268}{6.5}$, say 41 lbs. of coal of coal per hour, pumps the necessary feed, and heads it by 16 deg. F.

To effect a comparison, we may consider pumping the same quantity of water electrically, and heating the feed by live steam, assumed at 175 lbs. per square inch:—Water h.p. $= 3.58$; efficiency of pump and motor, 60 per cent. Then power required by motor, in kw. $= 3.58 \times \frac{5}{6} \times 0.746 = 4.5$ kw., which at 3 lbs. per kw.-hour, would result in a consumption of 13.5 lbs. of coal per hour. Quantity of steam to heat the feed 16 deg., $= 256$ lbs., requiring $\frac{256}{6.5}$ or 39.4 lbs. of coal. Total coal by this method, 44 lbs. which is therefore inferior as regards both steam economy and power to vary speed within wide limits.

Thus, apart from the question of capital cost, which is almost certainly in favor of the steam pump, a clear case can be shown for steam. But such superiority might vanish if, owing to the introduction of lubricant, an oil separator were rendered necessary, or the exhaust were wasted. Small reciprocating engines are inferior to electric motors in respect of upkeep, coal consumption, and stand-by losses when not in use, but kept ready for use; but small turbines are not necessarily so.

Reference was made at an earlier stage to a set consisting of a small turbine driving the condensing auxiliar-

ies; and it was shown that certain advantages accrued to such a use of steam if the exhaust could be profitably employed. We thus arrive at an argument of the following order:—In modern high-vacuum plants, the air-pump discharge is so much reduced in temperature that if introduced into an economiser without further heating it would cause sweating of the pipes. Consequently feed heating is a necessity. Steam feed pumps and turbine-driven condensing auxiliaries can be shown to have a thermal superiority over similar electrically-driven services if the exhaust be used to heat the feed, and are compact and easily maintained. To the extent, then, that the exhaust can be usefully absorbed for this purpose steam driving is clearly indicated for such services. But if the use of steam involves either waste of the heat of exhaust or the introduction of additional appliances, it ceases to have any recommendation as against electricity, with a possible exception in cases where speed variation within wide limits is required. It has been argued that steam offers a protection against failure of the auxiliaries in company with the main generators when a complete electrical breakdown occurs. In the system just described, the auxiliaries most essential to the restarting of the plant, viz., those connected with the condensers, would be steam driven.

To the advantage of steam it is to be added that it detracts nothing from the capacity of electrical generating and transforming plant, and little more from that of boilers than does an electric service.

Electric power, on the other hand, while it detracts from capacity of alternators, etc., has the following broad advantages:—(1) Small attention required while running. (2) Relative ease of installation at any distance. (3) Ease of control from any desirable point. The latter quality is particularly useful in the case of motors which drive stoker gear or fans; or for an object like a coal conveyor which extends over a great length and may have to be stopped from anywhere in case of accident.

Means of Providing Power.—Where steam is employed it can usually be taken from the main range. Cases sometimes arise where the main supply is superheated, but saturated steam is required for, say a feed pump; in such cases, provision can be made by drawing the saturated steam supply from two or three boilers, which are not likely to be shut down all at the same time. As regards electricity, the distinctive advantages of the three-phase current (absence of brushes or commutator, and solid and cheap construction) and its disadvantages (invariable speed) are well known. A three-phase supply for auxiliary circuits may be provided by three different methods:—(1) By separate transformers connected with each generating unit; (2) by transformers from the bus-bars; and (3) by separate auxiliary generating sets.

(1) The first-named, generally known as the complete unit system, wherein all the auxiliaries connected with any main generator are driven from a transformer attached to that generator, possesses advantages in the matter of reliability, but it is obviously costly. In isolated stations and with electrically-driven condensing auxiliaries, it is justified if not pushed to excess, as is liable to become the case where the boiler-house is concerned. Without an altogether disproportionate amount of spare boiler plant, each boiler-house or group of boilers must be considered the common property of the engine-house. Consequently a unit system must be interconnected in some way, which leads to expense and begins to vitiate the principle of unity. But apart from this, the argument against the alternative of driving from bus-bars, which is valid in the case of the turbine auxiliaries, is not necessarily applicable to the boilers. For a bus-bar failure, or a failure of one of the station transformers, does not vitally affect the supply of steam, if feed-pumps are steam-driven, and natural draft can be substituted for artificial; the grates (if mechanical) can be operated by hand, for long enough to enable the bus-bars to be made alive again, or the reserve transformer switched in. Coal or ash-handling plant, or the crane, cannot be allocated to any one turbine. It thus becomes necessary to have in any case a connection from the station bus-bars to the unit transformers. Apparatus which is inalienable from its own generator is usually confined to air pumps; and in some cases, circulating pumps and ventilator fans. Where the circulating and air pumps are steam-turbine-driven, and the alternator supplies its own draft, the principal arguments for the unit system are absent.

(2) A supply from the main bus-bars through transformers has an advantage over either of the other methods in the matter of initial cost. The transformers detract, of course, as much capacity from the main alternators as the unit method, and have to be in duplicate. Otherwise this system is exceedingly simple and obvious.

(3) The recommendations of the independent method are protection from electrical breakdown of the main system, and increased saleable capacity in the main alternators. The cost is necessarily much greater than that of the bus-bar method, and space has to be found for at least two auxiliary steam-driven generators with their equipment.

A supply of continuous current from a three-phase station can be furnished (1) by motor-generators, with or without a battery; (2) by independent generators. The advantage of continuous current is its particular applicability to variable-speed services, cranes and locomotives. With the addition of a battery, auxiliaries are quite independent of the state of the main bus-bars. After these things are granted, its disadvantages soon become apparent in the upkeep of commutators and brushes, increased initial cost, and perpetual loss in conversion by motor-generator or storage in the battery. This, of course, would not apply in a D.C. station.

In some cases where alternating current is generated, the device has been adopted of having some auxiliaries driven by alternating, and others by direct, current furnished by a motor-generator in normal operation, and by a battery if the supply fails. Thus some at least of the auxiliaries, and the station lighting, can always be kept going. But the introduction of two electrical systems is objectionable.

Conclusion.—We may now summarize the conclusions indicated by the foregoing remarks. Starting from the assumption that a large station is to generate three-phase high-tension current, certain services must be arranged for, some driven by steam, others by electric power. Preference is to be given to three-phase current which can be provided for either by independent generators, by transformers from the bus-bars, or by transformers from each generating unit. Being necessarily in duplicate and steam-driven, independent generators are a costly means for obtaining the power. It has been shown that turbine-driven air and circulating pumps, with the possible addition of feed pumps on the same shaft, besides fulfilling a useful and economical function in heating the feed, render unnecessary a subdivision of auxiliary services into unit groups. Therefore, it is submitted that such pumps, with other electric auxiliaries supplied by transformers connected only to the station bus-bars, combine simplicity with a sufficient measure of reliability. The transformers must, of course, be in duplicate. But where

for any reason, such as small size of units, with consequent wasteful consumption on auxiliary power, or excessive power rendered necessary by exigencies of the pumping system, steam cannot be economically adopted (having reference to the heating of the feed water), a grouping of motors into units, in which either one or two generators may participate, with electrically-driven condensing auxiliaries, is to be recommended on the score of immunity which it furnishes from simultaneous breakdown of all auxiliary services.

The following services may with advantage be electrically operated:—Mechanical stokers, if fitted; fans, if fitted (variable speed motors are desirable here, if efficient at low speeds; water service pumps of all sorts, except those very rarely used, where steam ejectors can be employed; economizer scrapers; coal and ash-handling plant; cranes.

The following should, where possible, be steam-driven: —Feed-pumps, and combined air and circulating pumps for the condensers.

Exciters should preferably be directly attached to the shafts of their generators.

Ventilation of alternators to be effected by fans on the rotors.

Switches to be electrically operated.

Large valves where speed of operation is essential may be operated either electrically, or, if the station is on a large enough scale to warrant a supply of compressed air always available for cleaning electrical apparatus and driving pneumatic tools, by air.

We may conclude by a brief reference to the tables which are appended to the Paper. Motor-generators and auxiliary D.C. sets are shown in separate column, as their inclusion among auxiliaries proper would be misleading. Steam feed pumps are estimated. A great divergence is exhibited in the degree to which auxiliary power is actually employed. Local peculiarities account for some of this divergence. For instance, in the case of Greenwich power is wasted due to the leakage of circulating water in connection with the straining appliances rendered necessary with Thames water, and electrically-driven feed pumps bulk largely in the total. At Carville, the station being set back some distance from the river in order to obtain suitable foundations, the power required for pumping water is considerable: on the other hand, practically none is needed for coal-handling owing to the advantageous use of the natural levels of the ground.

Of the two Glasgow stations, one (St. Andrew's Cross) employs fan-draft cooling towers, the other a canal. Hence the high figure in the case of the former.

At Stepney circulating pumps and fans account for much of the power. The latter also contribute a large proportion in the case of Brighton and Carville. In fact it is almost correct to say that they constitute the principal difference between the high figures and the low figures at Dunston where fan power is moderate and not duplicated.

Cambridge is of interest because it exhibits another factor of the auxiliary question. Being started as a single-phase station in days when single-phase motors were unsatisfactory, the bulk of the power is furnished by steam 12 h.p. only being electrical; the air and circulating pumps are for the same reason driven by gearing from the main turbines.

The installation of induced draft apparatus accounts for a large proportion of the power at the Newcastle and District Company's station. As a matter of everyday practice induced draft is not used there, but the fan motors are included because a classification has to be made on an uniform basis for comparison. The rated power of motors installed, which is the figure stated, is roughly a measure of the capital spent on auxiliaries. The daily energy used, which would be more indicative of the annual cost, might have been selected, but such a figure would be difficult (in some cases impossible) to arrive at: and the former figure perhaps brings out in a more striking fashion the importance of the whole question from the capital point of view.

Table I.—Aggregate of Auxiliary Power Installed at Various Stations.

STATION	Total main generating plant. kw.	Auxiliary power installed h.p.	Motor-generators or Auxiliary steam sets.	Auxiliary power h.p. per 1000 kw. of Main Plant.	Remarks
Lots Road, Chelsea	48,000 3-ph.	2,223	Four 135-kw. steam.	46.5	The 4 steam sets supply excitation and some D.C. motors.
Carville	35,000 3-ph.	3,411	Two 25-kw. One 100-kw. M.G.'s	97.5

A LARGE CONCRETE VIADUCT.

In municipal districts where railroad tracks traverse thickly populated sections the question of proper accommodation for safe and uninterrupted traffic across the railroad property has become a serious matter. At Weston, a small municipality just to the immediate west of Toronto, the problem has been solved by the erection of the concrete and girder steel viaduct forming the subject of the accompanying illustrations.

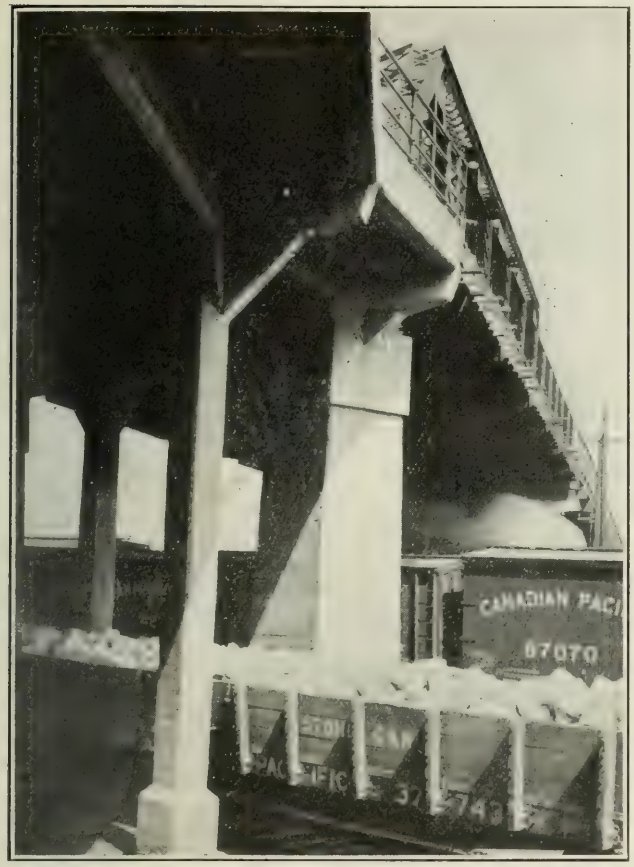

Fig. 1. View Showing Columns and Floor Beams.

A busy section of the main line of the Canadian Pacific Railway occupies the entire lower, open portions of the viaduct which, at this point is supported by a number of reinforced concrete piers. Leading to the spans an earthwork slope, held in place by a retaining wall of concrete, gives easy access to the higher parts of the structure. The entire length of the viaduct is almost 500 feet.

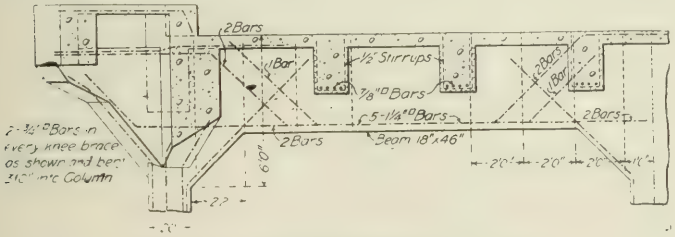

Fig. 2. Section through Bent Cap.

It is natural that the concrete columns supporting the central steel girder and bridge work should receive the major portion of the engineering attention. The footings for the columns were carried to a depth of 6 ft. below the ground level.; the area of the base being 64 sq. ft., stepped up to a 2 ft. by 2 ft. 4 in. area at the base of the columns. The columns are 16 × 20 in. reinforced by four ¾-in. bars, extending from the bottom of the footings up through the columns; at the top of which they are bent at an angle of 45 deg. passing through the floor-feams up into the floor slab. These bars are hooped with No. 12 gauge wire at 6 in. intervals.

The floor beams have a varying thickness, according to their position in the scheme, from a section of 16″ × 36″ to a section of 36″ × 50″. These beams are reinforced by four bars each.

The overhanging sidewalk and sidewalk supports are carried on cantilever arms reinforced with ¾-in. iron bars bent to the shape of the cement work which forms a right angle with the viaduct at the end of every floor beam. The sidewalk stringer is 12 × 24 in. and is reinforced with three ⅞-in. bars, two of which are bent up an angle of 45 deg., at each sidewalk bracket. The sidewalk is 4 in. thick and is reinforced with No. 16 gauge expanded metal. It is finished with a 1-in. facing of 1 part Portland cement, 1 part sand and 1 part screened gravel not exceeding ⅝ in. in diameter, which was floated to a smooth surface. The surface was marked off in blocks about 6 ft. in length and afterwards rolled with a patent roller.

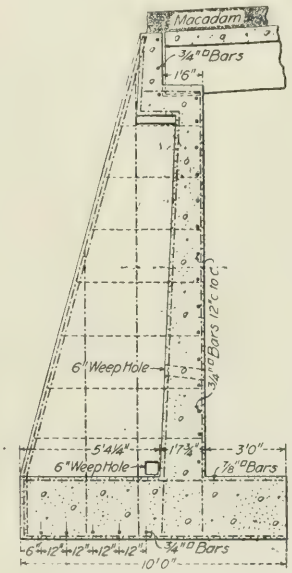

Fig. 3. Section Through Retaining Wall.

The bent supporting the steel span consists of two outer piers and a centre column. The outer piers are 6 × 6 ft. at the base, tapering to 5 × 5 ft. at the top and resting on footings each 10 × 10 ft. in area. These piers are reinforced with four ⅞-in. bars, one in each corner, and ½-in. stirrups spaced 12 in. on centres. The centre column is 20 × 20 in. with a base 2 ft. 4 in. × 2 ft. 4 in. × 2 ft. 8 in., resting on a footing with a base area of 8 × 8 ft. This column is reinforced with 4¾-in. bars hooped with No. 12 gauge wire.

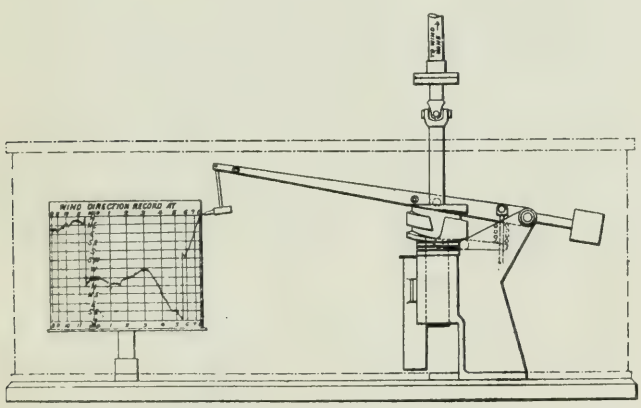
Fig. 4. View Showing Retaining Wall and Approach to Viaduct.

The sectional drawings, Figures 2 and 3, make clear the details of construction in the sloping approach. The footings of these walls from the lower end to the expansion

joints which are located 104 ft. from the lower end are 1 ft. 6 in. in thickness, increasing in width from 5 ft. to 7 ft. 4 in. and are reinforced with eight ⅝-in. horizontal bars, spaced as shown in the accompanying drawing, and ¾-in. transverse bars, spaced 12 in. centre to centre. At the expansion joint the footings are increased to 2 ft. 4 in. in thickness and widen it to 10 ft. at the abutment, at a distance of 120 ft. This portion is reinforced with five ¾-in. longitudinal bars and ⅞-in. transverse bars placed 12 in. centre to centre. The lower section of the retaining wall, 104 ft. long, is designed as a simple reinforced concrete wall, while the upper section, 120 ft. long, is designed with counterforts. Both sections are reinforced with a double system of rods, When the structure has taken a more finished appearance the earthwork will receive a coating of macadam pavement and by this means there will be completed a substantial road bed over the entire traffic way. The cost of this viaduct is estimated at $25,218. The contractor was Mr. C. E. Lewis, of Toronto, and the work was designed in the bridge department of the city engineer's office.

A WIND-DIRECTION RECORDER.

The wind-direction recorder which is shown in the accompanying figure, and was described in a recent issue of London Engineering, forms an example of a singularly simple solution of an awkward problem. The instrument, as will be gathered, consists of a pen which moves in a vertical plane, and traces a recording curve on the surface of a revolving drum. The pen is driven from a cam which is connected up to and actuated by a wind-vane, while the drum is driven by self-contained clockwork. The wind-vane is not



Diagrammatic Sketch of Recorder.

shown in the figure. It is mounted at the top of the vertical spindle, which is made of such length as may be necessary to enable the vane to be situated in an exposed position above the building in which the instrument is placed. Wind-direction recorders of other types than the present have, of course, been constructed. In one of these the chart is connected to the drum, and the pen is driven by clockwork, while others use two pens in various ways. The advantage of the present type lies in its extreme simplicity and in the fact that the movements of the pen are vertical and the charts rectilinear. It is obvious that an instrument having a simple and continuous groove in the cam could not be constructed on the lines of the figure, since with backing and veering winds the vane, after making a complete revolution, would cause the pen to so alter its zero in reference to the chart that the readings would become meaningless. In other words, if the vane is to be free to make complete revolutions in any direction—and this is, of course, essential—then there must be, at some point, a means of re-setting the pen on the chart. The simple method which has been devised for this purpose forms the main point of interest of the recorder under notice. As will be seen from the figure, the cam groove is in the form of a spiral, so that as the vane moves round, one way or the other, with a wind of varying direction, the pen either rises or falls on the chart. The zero adjustment is arranged for by the vertical slots at the ends of the cam groove, one of which can be seen in the figure. If, owing to continuous progression in one direction, the roller on the pen lever reaches one end of the spiral groove, it immediately moves through the vertical slot into the upper, or lower, part of the groove, as the case may be. The effect of this is naturally to trace a vertical line on the revolving chart, and at the same time to alter the zero of the pen. The chart, as will be seen, has a portion of its direction scale duplicated, so that after this vertical movement, the pen still indicates correctly the direction in which the wind is blowing. The instrument produces a broken curve of the type shown in the figure, but it is clear that such a curve presents no difficulties in reading. The details of the instrument are well shown in the figure. The pen lever is counterweighed and is also controlled by a spring. Its downward movement, when its roller travels in the vertical slot in the side of the cam remote from that shown in the figure, is brought about by its own weight; while its upward movement, when its roller is in the slot shown, is brought about by the spiral spring, which is compressed at the right moment by means of a lower lever, which has a roller working on the underside of the cam. This underside of the cam is formed to engage the roller of the second lever only when required. The pen lever is fitted up with a dashpot to prevent shock when it makes its quick vertical movements. The instrument is manufactured by Messrs. Negretti and Zambra, of 38 Holborn Viaduct, London, E.C.

MILLION-DOLLAR DAM.

According to a statement of Mr. A. S. Dawson, chief engineer of the department of natural resources of the Canadian Pacific Railway, Calgary, contracts have been let for a million-dollar work on the irrigation block. This includes a concrete aqueduct to cost half a million, other concrete structures to cost $300,000, and thirty steel bridges to cost one hundred thousand. The aqueduct is the first of its design to be constructed. It will be ten thousand five hundred feet long, with a maximum height of fifty-five feet, and will irrigate one hundred thousand acres of the Canadian Pacific block. The contract is awarded the Grant-Smith Company & McDonnel of Vancouver.

PLATINUM AT NELSON, B.C.

The investigation of the Geological Survey as to the platinum discoveries reported in Nelson last summer shows there is no foundation whatever for the statements then made that metals of the platinum group occur in the dykes in which they were reported. Two of the most reliable assayers who handled samples of the supposed platinum bearing dykes stated that they were unable to get even a trace, and their reports are now confirmed by the Geological Survey, as in all the samples taken by Mr. Leroy no platinum whatever was found with the exception of a doubtful trace in one sample.

TORONTO BUILDING BY-LAW.

The revision of the Toronto building by-law is nearly completed. It will be remembered that in May, 1911, a Citizens' Committee, composed of representatives of the technical and business organizations of the city, presented a memorial to the Mayor and the City Council, asking for a general revision of the by-law, and suggesting along what lines the revision should be done. The draft by-law for regulating reinforced concrete construction is now complete, and has been submitted to the Citizens' Committee for their opinion. A copy of the by-law will be found in this issue of *The Canadian Engineer*. The Citizens' Committee states that, in the main, the by-law as revised is acceptable. The committee offers a number of comments covering certain minor points on which the by-law is excessively severe. It must be said that the Citizens' Committee has secured a vast improvement in the conditions of the old by-law. The useless and prohibitive restrictions on reinforced concrete construction in the original regulations are, many of them, struck out, or so modified that the by-law as it now stands is a workable instrument; while severe, it is not excessively or unfairly so. It is unlikely that any further change will be made in the draft as published. With restrictive legislation against reinforced concrete construction reduced to a fair competitive basis, there is no question that there will be a great impetus in the number of buildings of this type which will be erected in Toronto in the future. The revision comes too late to have much effect on the building industry this year, but next season will undoubtedly show a great increase in the number of reinforced concrete buildings erected.

THE REPORT OF THE TORONTO WATER COMMISSION.

The report of the Commission appointed to investigate the question of Toronto water supply has at last been published. An abstract of the report will be found in this issue of *The Canadian Engineer*. On the whole, the recommendations made are what were expected. The Commission has taken a definite stand against Lake Simcoe water and in favor of Lake Ontario as a source of supply. Taking this view, naturally their decision is in favor of Scarboro' as a point of local supply on account of prevailing currents, etc. They mention, however, the possibility of an auxiliary lake supply later from the west of the city. One feature of the report which merits commendation is the emphasis placed on the prevention of waste by means of meters. We have in these columns emphasized the necessity of taking measures to prevent the criminal waste of water going on in Toronto, and it is high time steps were taken, either by the installation of meters or the organization of an efficient inspection department to cut down this waste. The present plant on the Island is to be retained, and it is recommended that the intake pipe and the filtration plant there be duplicated. The Commission reasons that on account of the already large outlay on the Island plant that it would be uneconomical and unnecessary to abandon it. We must confess that we find it hard to understand why the Commission recommends

slow sand filtration at the Island and mechanical filtration at Scarboro'. If one method is good in one place, why is it not good in the other? The water at both locations is Lake Ontario water, with little difference in quality and conditions of turbidity. If the slow sand filtration plant at the Island is not as good as the mechanical filtration plant at Scarboro' will be, why duplicate the present installation? The Commission may have good reasons for their recommendations, but these reasons have not been given in the report.

The report recommends an emergency chlorination plant in connection with the plant at Scarboro', at which it will be possible to chlorinate either before or after filtration. To avoid interruption of service, they recommend another independent source of electric power other than Niagara. It is an open question whether an auxiliary power plant, either steam, oil or gas, should not be provided rather than another electrical supply. The difficulties of electrical supply are mainly in the transmission systems, and a storm which would cause interruption of service on the Niagara line would probably have a similar effect on any other line.

RAILWAYS AND THE PEACE RIVER REGION.

The progressive railway policy in Alberta, planned by Premier Sifton, has again drawn attention to the possibilities of the Peace River country. The trend of settlement in Canada, and also in the United States, has been westward, following the construction of railways. As the land in the railway belts (the more southern part of Western Canada) is being rapidly filled, as the older railway lines throw out their feeders northward, and, as the location and construction of the new National Transcontinental Railway proceeds, attention is being attracted to the great northern reserves.

The two sections next likely to receive the greatest attention from capital and immigration are Northern Ontario and the Peace River district. We have previously discussed in these columns the possibilities of the former. Even the little known about the fertile Peace River country creates substantial hopes of future development.

At a point some 400 miles due north of Edmonton, for instance, splendid crops of wheat, barley, oats, peas, etc., have been regularly raised for over twenty years, the product for the season of 1906 being 25,000 bushels. That the production of grain in these northern, sparsely-settled regions has already resulted in the establishment of local grist mills of considerable capacity, which manufacture flour by modern processes. Potatoes and other vegetables have been for many years satisfactorily cultivated at Fort Good Hope, on the Mackenzie River, fourteen miles from the Arctic circle.

Vegetation matures quickly in northern latitudes, owing to the long days during the season of growth. According to a statement made to the Senate Committee, which took evidence regarding the unexplored regions of the Dominion in 1907, there is in the Peace River section as much good agricultural land fit for settlement, and yet unsettled, as there is settled in Manitoba, Saskatchewan and Alberta to-day.

Mr. J. K. Cornwall, an enthusiast regarding the Peace River region, considers the waterways of the Mackenzie watershed as the finest in North America. The most southern point reached by navigation on the Mackenzie watershed is at Fort McMurray, at the junction of the Clearwater and Athabaska Rivers, a point about 275 miles north, and a little east of Edmonton. The distance from McMurray to the Arctic ocean is approximately 1,600 miles. In all this distance, the connected waterways are navigable for steamers that are now plying upon them, and have been for twenty years. There are in this long system of waterways two distinct divisions.

The Peace River practically passes through the centre of the vast Peace River district, and in the development of this district will always play an important part, as navigation is practically without a dangerous rapid or obstacle of any kind throughout its whole course, with the exception of one at the Vermilion Chutes.

As to the number of months in the year that this stretch of waterway in the Mackenzie basin is open for navigation, Mr. Cornwall says that all the rivers running to the north, and each with their source in the Rocky Mountains, namely, the Athabaska, the Peace and the Liard, "go out" between April 20th and May 1st, on the average. They are all navigable a week after they go out, but where these rivers enter the lakes the navigation opens later, it being not much before the first week in June, when the lake ice breaks up and disappears. Navigation is opened on an average about the middle of June.

This waterway runs through a country of great natural resources. Timber, asphaltum, copper, salt and fish are some of its natural resources. The agricultural possibilities of the Peace River district are unsurpassed in the North-West. Flour is ground at Fort Vermilion, which is 670 miles north of the United States boundary, and is in latitude 58.30. The Hudson Bay Company has a large and excellently equipped flour mill there which cost $45,000.

As progress is made in the Alberta government's railroad programme, we shall hear much more regarding the Peace River region, rich in possibilties and natural resources.

EDITORIAL COMMENT.

If it is true, as reported, that Mr. K. L. Aitken, the managing engineer of the Toronto Hydro-Electric Commission, will not return to take up his duties after his six months' leave of absence, it looks to us as if the Commission were making Mr. Aitken the scapegoat for the troubles they see looming up, and which they are primarily responsible for. We have had occasion to criticize the Toronto Hydro-Electric Commission before, and we feel that it is not too late even yet to replace the present Commission with one more thoroughly in touch and in sympathy with the Ontario Hydro-Electric Commission.

* * * *

In the inquest being held over the collapse of the Neilson building in Toronto the testimony of the witnesses has been of considerable interest. We do not care to comment on the accident until the inquest is closed. The evidence of the Assistant City Architect as given on Monday last, however, shows a most remarkable lack of appreciation of the eccentric loading of walls, and his evidence throughout has been conspicuous in his misunderstanding of the terms, "factor of safety" and "safe load."

REPORT ON TORONTO WATER.

During the latter part of 1910 and early in 1911, serious conditions developed in connection with the water supply of the city of Toronto. These conditions were, apparently, due to the failure of the seventy-two inch steel intake pipe, which partly filled with sand, thus cutting off the lake supply from the city. During the month of February, 1911, the city was compelled to fall back upon the Blockhouse Bay as its source of water supply. At this time the citizens were advised to boil all water used for domestic purposes.

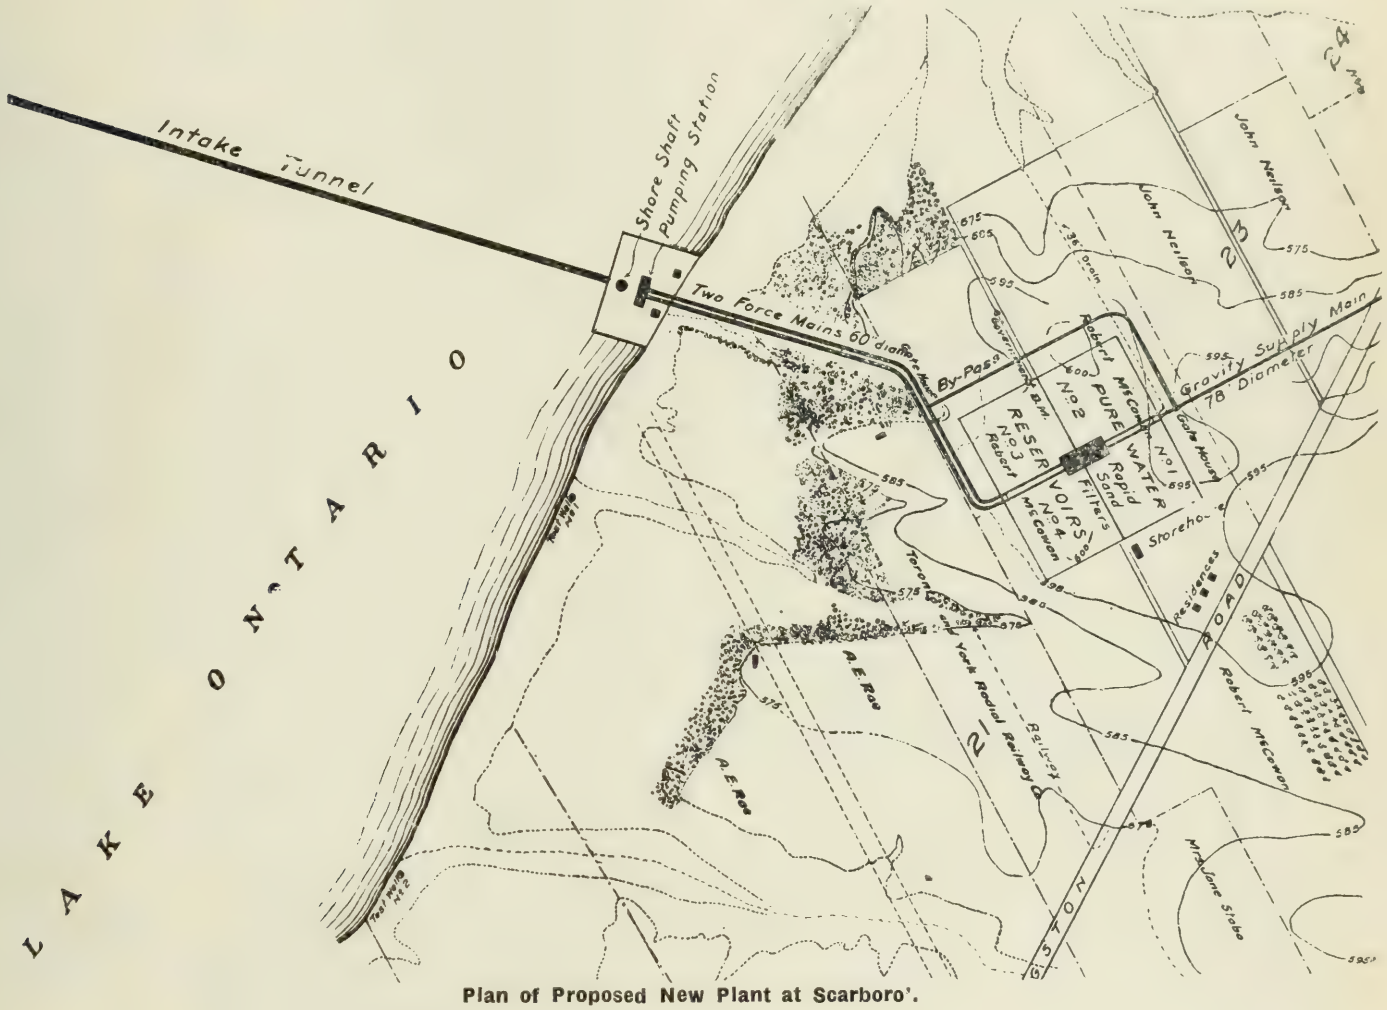
The chlorination plant, which had been in continuous operation since March, 1910, so purified the water, however, that there was no apparent increase in disease that could be attributed to the use of the Bay water. It was reasonable to conclude, however, that after the breaking up of the ice, the polluted harbor water might readily find its way to this temporary supply, and the advent of warm weather would increase the danger.

The waterworks department was then strenuously engaged in removing sand from the intake pipe in order to secure lake water at the earliest possible moment.

At this same time a sand filtration plant was under construction for treatment of the water supply.

The above circumstances, together with an acknowledged general feeling that the whole question of the present system of water and future requirements demanded immediate consideration, led the city council to ask for an independent examination and report. A board of consulting engineers was appointed, composed of Messrs. Isham Randolph, J. G. Sing, T. Aird Murray and W. Chipman, to consider the question, and they have now formulated and presented their report. An abstract of their report appears herewith.

A first interim report was presented to the Board of Control on March 24th. This report dealt exclusively with improving the supply, which was then being drawn from Blockhouse Bay, as it did not appear that Lake Ontario water could be obtained through the intake pipe for some considerable time. It was recommended that "Long Pond" be converted into a settling basin by constructing three dams on the harbor or city side leading from the harbor, and that a cutting be made to Lake Ontario at Clandeboye Avenue, across the Island, in order to introduce lake water into the pond. This report was adopted and the work immediately proceeded with, but it was not until May 10th that it was completed, from which time to June 29th, the city supply was drawn from the lake by way of Long Pond.



Plan of Proposed New Plant at Scarboro'.

For the first three months the greater part of this board's time was occupied with problems connected with protecting the temporary city supply from contamination while repairs were being made to the intake pipe, and in designing a new duplicate intake pipe to ensure a constant supply to the system.

Surveys, soundings, collection of and analyses of samples of water, and compilation and study of data, have been in almost continuous progress since the appointment of this board. Two test wells were also sunk on the beach at Scarboro' to determine the character of the underlying strata, about which there existed conflicting opinions.

The recommendations and estimates of cost with reference to a supply of water from Scarboro' are here given.

Recommendations and Conclusions.—(a) That the present and future source of water supply for the city of Toronto must depend solely upon Lake Ontario.

(b) That bacteriological, chemical and visual examinations of Lake Ontario water from Mimico to Scarboro' Heights have demonstrated that there is no locality within ten miles from the north shore of the lake from which water can be drawn which will at all times present a safe supply, unless such water be subject to some form of purification Although it is also apparent, from the evidence gathered, that water in the immediate vicinity of the city is subject to a greater degree of impurity for longer periods than water at a distance. It is also concluded, from the evidence, that

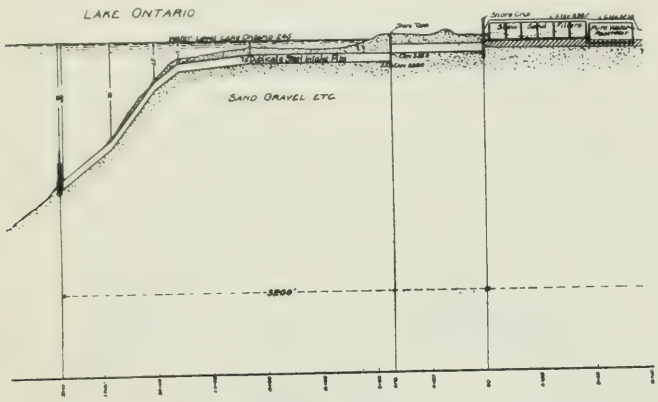


Diagram Showing New Intake Pipe.

the transporting lake currents are from the east to the west, and that there is a lesser probability of impure water to be met with off Scarboro' than off Mimico.

(c) That, taking into consideration the existing system, including filtration works, intake, conduits, tunnel under the bay, pumping machinery, large mains, and reservoir, it would be uneconomical and unnecessary to abandon it.

That the entire system should, however, be maintained in a proper condition of efficiency and each part or section brought up to a safe minimum capacity of at least sixty million gallons per day.

(d) That, by laying the duplicate intake pipe, now under contract, the duplication of the filtration plant, the connecting up of the sixty-inch steel conduit across the Island, and the installation of additional pumping machinery at John Street station, the existing system may be relied upon to supply sixty million gallons per day, and for a short period may meet a demand of ninety million gallons.

And that these proposed improvements be immediately undertaken, otherwise the city will undoubtedly be confronted with a water famine in the immediate future.

It is concluded that until the second intake be completed, Long Pond be retained in such condition that it may be converted into a settling basin for the city water supply upon twenty-four hours' notice.

(e) That all available evidence points to the necessity of increasing the water supply to meet the demands of one million population, and that it is not advisable to rely upon the present location for such increased supply. Taking into consideration the probable future rapid growth of the city, it is reasonable that the present location of supply be considered only as a central unit, and that extra units be installed either east or west of the central unit. That, owing to the demonstrated fact that purer water is obtainable for longer intervals of time east of the harbor than to the west, and owing to the high elevations of the plateau at Scarboro', a second unit be first installed at this location.

That all preliminary surveys, plans, etc., for the Scarboro' system be proceeded with immediately and works placed under contract.

It is concluded that, until Toronto can be assured of a second independent and reliable supply of water from the lake, what have been considered as exceptionable and unpreventible circumstances may again arise to the discomfort of the citizens and consequent lack of confidence in the organization of the waterworks department of the city.

The possibility that a third unit of supply may in the future be required to the west of the harbor, is admitted but not as yet anticipated.

(f) That, owing to the fact that the city is about to discharge its sewage into Lake Ontario at a point about two and one-half miles east of the harbor, it is of the utmost importance that the sewage be so treated that infectious matter be destroyed before being so discharged. That it is not apparent that the city is at present, by the proposed method, about to dispose of the sewage in a manner and to a degree which will insure a safe water supply from Lake Ontario in the vicinity of Toronto.

Improvements to Existing System.—In the interim report of November 30th a brief description is given of the improvements proposed to the existing system, together with an estimate of cost.

Protection works in connection with the old intake pipe were not fully completed in December last, and there exist grave reasons for doubting the stability of the old intake pipe, which was broken in February, 1911, and out of commission from that date until August. Dredging for the proposed duplicate intake progressed during the latter part of last season, but no pipes have yet been laid.

The filtration plant, with a nominal capacity of forty-five million Imperial gallons per day, was completed in December 1911, and by January 4th all of the filter beds were in operation. The pumping machinery, however, for lifting the water from the lake level to the filters has not the capacity specified, but this matter will probably be remedied by the contractors. The filtration pumping station is much too small for the machinery installed therein, and this board includes in the proposed improvements an extension of the filtration pumping station to the southward. Some of the machinery in the existing building may be moved into the

Sketch Showing General Proposed Extension.

extension proposed, and there should also be installed therein a second steam pumping unit and duplicates of the electrically operated machinery. It may not be necessary, at first, to double the capacity of the filters, but another pure water reservoir should be immediately constructed and a sufficient area of filters to meet the maximum demand for water that may be anticipated during the time that the Scarboro' project may be under construction.

The construction of the second reservoir will permit the existing one being emptied for cleaning, inspection and repairs. By the by-pass pipes shown, the contents of either

of the pure water reservoirs may be discharged into either of the conduit pipes. In case of accident to either intake, the arrangement shown will permit water being drawn from Long Pond to the filtration plant pumps and from thence passed through the filters and the second conduit to the tunnel.

A connecting pipe about 600 feet in length is to be laid from the sixty-inch conduit to the south shaft of tunnel, provided with valves at each end. This pipe is to be laid below the bed of the bay.

At the John Street pumping station the board recommends that a steam operated pumping engine of twenty-five million gallons capacity be added, or it may be advisable to substitute two fifteen million gallon units in lieu of one twenty-five million gallon unit. To accommodate this machinery it is proposed to extend the 1904 pump house westerly.

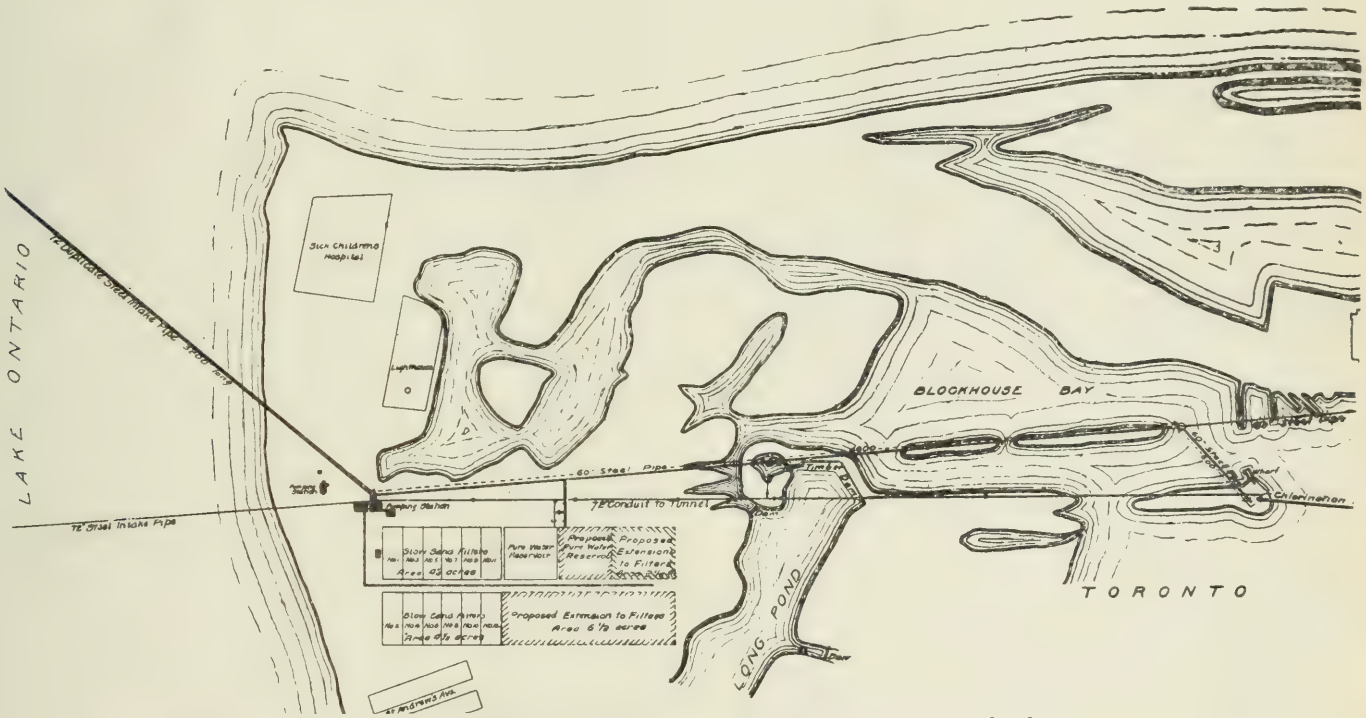
It would also now appear advisable to add two additional electro-turbine units each of not less than thirteen and one-half million gallons capacity.

If the electro-turbine units are added, and the two steam units substituted for the larger unit recommended, then the estimate of cost given in the interim report should be increased by $157,000, making a total of $1,287,000 exclusive of the duplicate intake pipe.

At Cleveland, Ohio, with Lake Erie as a source of supply, the general metering of the services was decided upon in 1901, at which time about six per cent. of the services were metered, the per capita consumption per day being one hundred and sixty-nine U.S. gallons, or one hundred and forty-one Imperial gallons. The reduction effected in the consumption was as follows:

Year.	Number of Services	Percentage Metered.	Gallons per Capita.
1901	55,130	6.42	169.40
1902	56,816	19.88	167.80
1903	58,852	42.81	141.60
1904	60,627	50.09	138.50
1905	64,137	69.70	130.80
1906	69,128	82.19	123.00
1907	72,225	88.60	117.50
1908	74,490	93.61	100.30
1909	76,777	97.48	93.64
1910	80,686	97.67	101.80

With fifty per cent. of the services metered the consumption was only reduced seven per cent.; with seventy-five per cent. metered the reduction was twenty-five per cent., and with practically all of the services metered, forty per cent. reduction.



Plan Showing Proposed Extensions to Present Plant on the Island.

The foregoing estimate will include a new forty-eight-inch force main from the pump house to Front Street, with connections to existing mains.

Waste Prevention.—The problem of waste prevention by the installation of meters, and efficient inspection, has not been considered in detail by this board, so far as Toronto is concerned, as it is understood that the city is taking up the question by means of a special committee. It is concluded, however, from the experience of this board, that the general metering of the domestic supply, with a minimum charge for each service, would reduce the per capita consumption by approximately one-third, and that the cost of installing the meters would be more than compensated for by the reduction in the cost of delivery. Furthermore, the existing plant could be made to supply a third more population than at present.

The main argument that is now urged against the adoption of meters is the cost of installation, and the maintenance charges. The argument that meters restrict the use of water has proven fallacious from experience, and may be dismissed.

As to the cost, the results at Cleveland are of value. At the end of 1910, 78,809 meters were installed, the cost of the meters and setting being $1,340,000, but this included several thousand meters in stock. The average cost of each meter set was about $17.50. The setting in the basement cost less than $4 each, and during recent years a larger percentage are being set in the basements. Of the eighty thousand meters over seventy thousand are on services five-eighths inches in diameter. The largest size of meters may be installed in brick chambers, but it will be found more economical and convenient to instal them in basements.

In Toronto, the cost of the meters would be higher than in Cleveland, also the cost of the setting, but as the great majority of the buildings in this city are of brick with proper basements and cellars, it would not be necessary to construct many brick vaults or chambers. To meter the entire city would cost approximately as follows:

60,000 meters set in basement, at $14	$840,000
10,000 meters set in vaults or chambers, at $30	300,000
Total	$1,140,000

The interest and sinking fund on the above amount may be estimated at $60,000 per year. At Cleveland the annual maintenance charges are less than thirty cents per meter. It may be assumed, therefore, that the maintenance charges in Toronto would be $20,000 per year. The depreciation may be taken at six per cent., or $66,000. This gives a total annual expenditure of $146,000 for metering.

By the report of the city engineer for 1910, Schedule 21, the cost of supplying water in Toronto is given for that year as five and three-quarter cents per thousand gallons, delivered to the consumer. This cost is the highest since 1894, the average for the twenty-six years being about five cents per thousand gallons.

The filtration plant constructed in 1910 and 1911, which has been in operation since January, 1912, will probably increase the cost of the water by three-quarter cents per thousand gallons, making a total of six and one-half cents per thousand gallons, or $65 per million for 1912.

The prevention of a waste of fifteen million gallons per day would, therefore, result in a total annual saving of $355,875. It is quite true that the cost of pumping and filtration is only two cents per thousand gallons, but the waterworks system must be considered as a whole, of which the pumping machinery and filtration plant is only a part. If more water is to be pumped through the mains, they must be increased in capacity or in numbers, and larger conduits will be necessary, as all parts of the existing system are now taxed to their full capacities in the summer months.

The general adoption of meters in the city of Toronto would probably result in a saving of $200,000 per annum.

Estimates of Cost of Specific Recommendations Made in Existing System.

(As Given in Interim Report No. 3.)

Duplication of Island filtration plant	$750,000
Lowering, repairing and connecting the sixty-inch conduit in Blockhouse Bay	50,000
One 25,000,000-gallon pumping engine	155,000
Three 200-h.p. boilers	20,000
Engine house and boiler house, complete	50,000
Engineering and superintendence, 10 per cent.	105,000
Total	$1,130,000

(Extra Expenditure not Given in Interim Report No. 3.)

Duplication of intake pipe	$333,000
Substitution two 15-million gallon pumping units for one 25-million gallon engine	40,000
Two electro-turbine units, each 13½-million gals. capacity	60,000
Additional boiler	7,000
Additional buildings	25,000
Force main, 48-in., across Esplanade to Front St.	10,000
Engineering and superintendence, 10 per cent.	15,000
Total additional	$490,000

Cost of meters:

60,000 meters set at $14	$840,000
10,000 meters set at $30	300,000
Total cost of metering	$1,140,000

Description of Proposed New Works.—The supply of water for the proposed new system is to be drawn from the lake at a distance of about two miles from shore, and opposite lot 16 in the township of Scarboro'. At this point the depth of water is about one hundred feet.

The proposed intake crib will be of reinforced concrete and steel, with a diameter of one hundred and ten feet at the base, and a height of about one hundred and fifteen feet. This crib will be sunk into the shale and clay of the lake bed, and the compartments filled with concrete. The inlet shaft will be sunk vertically from the centre of the crib to the elevation of the tunnel, from which point work on the tunnel will be prosecuted towards shore.

The interior of the crib will be an open cylinder about seventy feet in diameter, into which the water from the lake will flow through a number of ports at different elevations, controlled by valves, by means of which the supply may be drawn from any desired depth.

The crib is to be covered by a concrete and steel building surmounted by a small lighthouse for the guidance of vessels.

The proposed location of the intake crib is seven miles east from the effluent discharged from the Morley Avenue sewage disposal works, the existing water intake being five miles to the west. Furthermore, the transporting currents are westward rather than eastward, as pointed out in the observations upon the lake currents. All currents caused by easterly and south-westerly winds have a tendency to follow the shore line, consequently the greater the distance the intake be located from the shore, the less the turbidity.

At the point selected the turbid zone rarely extends one-half mile from shore; further, between Ashbridge's Bay and Highland Creek, there are no surface streams of any consequence discharging turbid water into the lake. The watershed adjoining the lake at Scarboro' presents a very limited area of land draining toward the lake, and can have practically no effect on its purity. A small amount of surface water now drains through a number of small water courses and gullies from the highlands to the shore. This area will, no doubt, become a residential section of the city, from which the domestic sewage may be conveyed by gravity to the main sewage disposal works near the Woodbine, while the greater part of the storm water may be diverted northward to the Don and Highland Creek.

From data obtained from the office of the Geological Survey, Ottawa, and other sources, the surface of the Hudson River geological formation was assumed to be at a depth of less than one hundred feet at the shore line at Scarboro'. Two test wells were sunk by this board on the beach, in each of which the surface of the rock was struck about fifty feet beneath the lake level. The depth at which the rock of the Hudson River formation is struck on the south side of Lake Ontario has been determined by borings, and the vertical distance to the top and to the bottom of the formation has also been determined at a few points along the north shore between Highland Creek and Mimico, from which it may be safely concluded that the Hudson River shales form the bed of the lake for some miles southward from the north shore, although the rock surface may be overlaid with a few feet of clay, sand and silt.

The intake crib is to be connected with the pumping station at the shore by a tunnel two miles in length and ten

feet interior diameter, to be constructed in the shale of the Hudson River formation at a depth of about one hundred and sixty feet below the lake surface, to avoid as far as possible the infiltration of water. At the shore end, a vertical shaft will be constructed one hundred and sixty feet in depth, through which the water will rise to supply the pumping machinery.

Before preparing detailed plans of the intake crib and tunnel, a sufficient number of borings should be made along the line of the proposed tunnel to determine accurately the surface of the Hudson River shales and the character of these shales for some feet in depth. This work can only be performed advantageously in the summer months, and should be proceeded with during the coming season.

At the shore end of the tunnel about five acres should be enclosed by a concrete breakwater, the interior space to be filled by materials excavated from the tunnel, and the surplus from the grading on shore.

Upon the site thus formed a pumping station is to be erected, also shop and residences for engineers, office, etc. The building may be of brick or reinforced concrete, fireproof throughout.

The pumping machinery will comprise four electrically operated high pressure turbine pumps, each of fifteen million Imperial gallons capacity per twenty-four hours. Three of these units should be installed at first, and space left for two or more additional units.

Electric current is to be transmitted to the new pump house from the municipal hydro-electric sub-station to be erected at the south-east corner of Gerrard Street and Carlaw Avenue, a distance of about eight miles. To avoid all possibility of interruption to the service, another independent source of electric power should be connected with the pumping station, preferably from the Trent Valley or some source other than Niagara.

From the pumping station two parallel rising mains of steel, each sixty inches in diameter, will convey the water to filtration works on the plateau above, the total lift being about three hundred and seventy feet. These two mains are to be laid on a grade not exceeding forty-five degrees at any point on the line, the total distance from the pump house to the filtration works being two thousand feet.

As the water supply off Scarboro' will be free from turbidity, excepting after heavy gales, and as the possibility of sewage pollution from the city will be less than at the existing intake, and as this pollution can only occur with strong westerly winds, the necessity of filtration may not at first be apparent; but, it should be borne in mind that bodies of infected water are floating in the lake, and to guard against the possibility of danger from this source, it is advisable that the water should at all times be filtered.

The board has concluded that a mechanical filtration plant will meet the requirements at Scarboro', and will cost less than a slow sand filtration plant similar to that on the Island.

The filter tanks or beds are to be constructed over the reservoirs.

A chlorination plant for emergency service is also to be provided in connection with the filtration plant, so located that the chlorine may be applied to the raw water or to the filtered water.

The capacity of the reservoir estimated upon will be one hundred and thirty million gallons, equivalent to twenty acres in area and twenty-five feet in depth. By subdividing the reservoir into four units, opportunity will be given for repairing and cleaning. The reservoirs will be constructed of reinforced concrete, and covered by a groined roof.

The outlet from the reservoir will be through two or more pipes leading to one supply main By means of by-pass pipes the supply may be pumped directly from the pumping station into the main leading to the city.

About forty acres of land will be required for the reservoir and filtration works, but this board recommends that one hundred and twenty acres be purchased, or all of lot 22 between Kingston Road and the lake. The pumping station and the rising mains will be located on lot 21, which adjoins lot 22 to the eastward.

Estimated Cost of Scarboro' Project.

1.	Intake tunnel, 10,560 lineal feet, 10 feet diameter	$633,600
2.	Shore shaft, 160 feet at $150, and lake shaft, 60 feet at $150	33,000
3.	Intake crib	500,000
4.	Pump house site, retaining wall	80,000
5.	Pump house	30,000
6.	Pumping machinery, 60 millions capacity (4 units, 15 each)	150,000
7.	Transmission line, 8 miles	48,000
8.	Rising mains, two 60-inch pipes, each 2,000 feet long	80,000
9.	Grading for and laying rising mains	20,000
10.	Land for filtration works, reservoir, etc., 120 acres, at $600	72,000
11.	Filtration works, mechanical filter, capacity 60 millions per day, machinery and laboratory	653,400
12.	Covered reservoir, 130 millions capacity	1,071,000
13.	Gravity supply main from reservoir to high level pumping station, 55,000 feet steel pipe (delivered)	880,000
14.	Excavating for, laying, and covering at $5 ..... $275,000 Tunnel at Castle Frank, 1,200 ft., at $25 extra ..... 30,000 Crossing River Don, extra 15,000	320,000
15.	Main from high level pumping station to West Toronto, 17,500 feet. 48-in., 42-in., and 36-in. (laid)	262,500
		$4,833,500
16.	Ten per cent. for contingencies, engineering, etc.	486,500
	Total estimated cost	$5,320,000

From the Scarboro' reservoir the water supply will gravitate to the city through a steel conduit, the diameter from the reservoir to East Toronto being seventy-eight inches, from East Toronto to the westerly side of the Don seventy-two inches, and from the last named point to the existing pumping station at Poplar Plains Road, the diameter may be reduced to sixty-six inches. This gravity main is to be laid along the concession road allowance westerly from the reservoir to the north side of the G. T. Ry., thence following the north-westerly side of the G. T. Ry. to Danforth Road, thence westerly along Danforth Road and Danforth Road produced, to the westerly side of the River Don, thence by a tunnel under the Castle Frank Hill to the Rosedale Ravine, thence along Rosedale Valley Road and McPherson Park to Yonge Street, thence via Ramsden Park, Peers Avenue, Avenue Road and McPherson Avenue, to the high level pumping station.

The pressure from this gravity supply main will be sufficient for all that portion of the city located south of the escarpment known as Wells Hill in the central part of the city, and all south of the easterly branch of the Don in the easterly part of the city. East Toronto area, now supplied by the intermediate service, and West Toronto, will thus be supplied from the Scarboro' reservoir by gravity. For the

higher districts, lying north of Davenport Road and the easterly branch of the Don, it will be necessary to repump the water required, and as this district is rapidly increasing in population, additions to the pumping machinery will be frequently demanded.

By the adoption of the Scarboro' scheme, all of the existing pumping machinery at Poplar Plains station may be used for the highest district, the intermediate district being served by gravity.

In the West Toronto district and the East Toronto district, it may be eventually found desirable to instal booster pumping stations for general service, but in the low level district and the intermediate district, it would be a mistake to increase the ordinary pressure materially for fire service, although in the out-lying districts it may be permissible to do so.

A large supply main is also to be laid from the intersection of Avenue Road and McPherson Avenue westerly along McPherson, Bridgeman, Main, Brandon, Kingsley, Pelham and Lyndon to West Toronto, this main to be forty-eight inches in diameter at McPherson, reducing to thirty-six inches at Lyndon.

It is estimated that the construction of the proposed Scarboro' works will take from three to five years to complete.

POWER SITES IN THE WEST.

Notwithstanding the various rapids, the North Saskatchewan River may be considered a navigable stream throughout its length from the head of the Grand rapids, near Lake Winnipeg, to Edmonton and beyond. For many years, it has been navigated by the Hudson's Bay Company's steamboats, which make one or two trips a year to carry supplies for the posts.

The Bow River rises in the watershed of the Rocky Mountains, and flows in a southeasterly direction until it reaches the foothill country at the "Gap." It then turns to the east as far as Calgary, and, thence, runs south and east to its confluence wih the Belly River. Between its source and the "Gap," a number of streams flow into it from the various mountain valleys that it intersects. Almost immediately after leaving the mountains it is joined from the south by the Kananaskis River, a stream of good size and fairly uniform flow, which has its source in the eastern ranges of the Rocky Mountains in muskegs and lakes lying at a considerable elevation. From this point to its confluence with the Belly River, the Bow furnishes the run-off channel for the eastern slope of the Rocky Mountains and is fed by numerous streams. It is broken in several places by falls and rapids. At Calgary, a hydro-electric plant, operating under a low head of 14 feet, derives its power from one of these. A large development at Horseshoe and Kananaskis Falls, where a head of 70 feet is obtained, is now completed.

Rising in the watershed range of the Rocky Mountains and receiving many glacial tributaries, the Athabasca River contains many valuable power sites between its source, at an altitude of about 5,000 feet, and its debouchement into Lake Athabasca at an altitude of 690 feet. Of these, the most noted are at the succession of falls and rapids known collectively as the Grand Rapids. As they can only be rendered navigable by canals, the question of interference with navigation does not require consideration.

The remarks respecting the Athabasca also apply in large measure to the Peace River. In addition to the power sites in the ranges west of the Rockies, there are two important sites on this stream. The upper is at Rocky Mountain portage. At this point the river is a raging torrent flowing 25 miles through a canon, and has a total fall of 270 feet. The lower is situated at Vermilion fall, the only interruption to navigation between its confluence with Slave River and above Dunvegan, a distance of upwards of 530 miles.

NEW BUILDING BY-LAW FOR TORONTO.

The text of the new by-law for Toronto regulating reinforced concrete construction is given below. Some slight changes may be made before the by-law is ratified by the City Council.

1. The term "reinforced concrete" as used in this by-law is to be understood to mean an approved concrete mixture reinforced by steel of any shape so combined that the steel will take up the tensional stresses and assist in the resistance to shear, and the construction must be of such a nature that the stresses can be calculated by the accepted formulas of modern engineering practice.

2. (1) Before permission to erect any reinforced concrete structure or any structure containing reinforced concrete is issued, complete drawings and specifications, signed by the architect or engineer who designed the structure and clearly showing all details of the proposed construction, and the size, shape and position of all reinforcing rods, stirrups or other forms or metal, also a certified copy of the computations of the architect or engineer showing how the strength of the different portions of the structure was arrived at, shall be submitted to the department of the city architect and superintendent of building for examination and approval, and when satisfactory, the approved signed drawings, specifications and static computations shall be filed in the said department until the completion of the work, provided, however, that permission to erect any reinforced concrete structure does not in any manner imply the acceptance of the work or relieve the architect or engineer who designed the structure from full responsibility for the actual construction.

(2) All reintorced concrete construction shall be performed under the personal and constant supervision of either a fully qualified engineer or competent superintendent.

(3) It shall be the duty of the engineer or superintendent in charge of the work to keep an exact record of the progress of each operation, which record shall clearly show the position of and give the date of placing of all concrete and the date of removal of forms, a certified copy of which is to be furnished the inspector of buildings weekly, and upon the completion of the work the correctness of the records, which have been furnished weekly, to be certified to and sworn to, if considered desirable, by the person under whose constant supervision the work was carried out.

(4) Inspection by the engineer or superintendent in charge shall cover the following:

(a) The materials;

(b) The correct construction and erection of the forms and supports;

(c) The sizes, shapes, arrangement and fastening in position of all reinforcements;

(d) The proportioning, mixing and placing of the concrete;

(e) The strength of the concrete by tests of standard test pieces made during the progress of the work;

(f) Whether the concrete is sufficiently hardened before the forms and supports are removed;

(g) Prevention of injury to any part of the structure by and after the removal of the forms;

(h) Comparison of dimensions of all parts of the finished structure with the plans.

(5) The execution of reinforced concrete work shall be confided to workmen accustomed to this class of construction who shall be under the control of a competent foreman, and it is to be distinctly understood that under no conditions will the engineer or superintendent in charge of the work be permitted to act in the dual capacity of both inspector and foreman.

Forms.—3.—(1) All forms shall be built rigid, plumb and true, thoroughly braced and with tight joints so that no appreciable part of the concrete mixture can escape, and their interior dimensions must conform to the dimensions of the concrete sections shown upon the approved plans. All forms shall be supported so as to carry the dead load of the construction as a liquid without spring or deflection, and any form that becomes twisted or warped shall be correctly adjusted before concrete is placed therein. Building paper will not be allowed in forms for any purpose whatsoever.

(2) If forms are to be hung from steel beams the hangers and the method of hanging shall be subject to the approval of the inspector of buildings, and no hangers that are difficult to remove shall be used.

(3) The forms for beams, girders and lintels shall be so designed that at least one side of each beam or girder may be removed without disturbing the bottom portion of the form or its supports.

(4) All posts supporting forms for slabs, beams or girders must rest upon wedges which can be loosened and removed without producing undue strains in the floor or roof system.

(5) Posts which are to be supported from the ground must be provided with footings of sufficient area to do away with any liability of appreciable settlement owing to insufficient foundation.

(6) All column forms shall have an opening left at the bottom to enable cleaning out and adjustment of the steel to be attended to, which opening is not to be closed until the column is to be poured.

(7) All shavings, chips, sawdust, ice or other foreign matter must be removed from within all forms before concrete is placed therein.

Cement.—4.—(1) Only Portland cement will be accepted in reinforced concrete construction and this cement must comply in all respects with the requirements of the standard specifications of the city engineer's office of the city of Toronto, which are as follows:

(a) The specific gravity of the cement shall not be less than 3.10. Should the test of cement as received fall below this requirement, a second test may be made upon a sample ignited at a low red heat. The loss in weight of the ignited cement shall not exceed 4 per cent.

(b) It shall leave by weight a residue of not more than 8 per cent. on the No. 100 and not more than 25 per cent. on the No. 200 sieve.

(c) It shall not develop initial set in less than thirty minutes and must develop hard set in not less than one hour, nor more than ten hours.

(d) The minimum requirements for tensile strength for briquettes one square inch in cross section shall be as follows, and the cement shall show no retrogression in strength within the periods specified:

Age.	Neat Cement.	Strength.
24 hours	in moist air	175 pounds
7 days	(1 day in moist air, 6 days in water)	500 "
28 days	(1 day in moist air, 27 days in water)	600 "
	One part cement, three parts Standard Ottawa sand.	
7 days	(1 day in moist air, 6 days in water)	200 "
28 days	(1 day in moist air, 27 days in water)	275 "

(e) Pats of neat cement about 3 inches in diameter one-half inch thick at the centre and tapering to a thin edge shall be kept in moist air for a period of 24 hours.

(f) A pat shall then be kept in air at normal temperature and observed at intervals for a least 28 days.

(g) Another pat shall be kept in water maintained at as near 70 degrees F. as practicable and observed at intervals for at least 28 days.

(h) A third pat shall be exposed in any convenient way in an atmosphere of steam above boiling water in a loosely closed vessel for 5 hours.

These pats to satisfactorily pass the requirements shall remain firm and hard and show no signs of distortion, discoloration, checking, cracking or disintegrating.

(i) The cement shall not contain more than 1.75 per cent. of anhydrous acid (SO_3) nor more than 4 per cent. of magnesia (MgO).

(2) No cement shall be used in any reinforced concrete work unless it has been tested either at the manufactory or at some acceptable laboratory and a certified report of the test filed with the inspector of buildings.

(3) All such tests shall be made in not more than carload lots or in smaller quantities if so directed by the inspector of buildings, and when laboratory tests are to be made the cement shall be delivered at the job at least two weeks before it is required for use so as to allow ample time for testing.

(4) Proper care is to be taken to separate lots delivered so that they can be easily identified if found unsatisfactory, and a suitable place must be provided for the storage of all all cement. No cement shall be used that has absorbed sufficient moisture to cause it to granulate or become lumpy when thoroughly dried.

(5) Any cement without the makers' name and brand on the barrel or package will be rejected without test, as will also any cement in barrels or packages bearing other than the makers' name and brand.

(6) The inspector of buildings may require a certificate from the manufacturer to the effect that the cement has been seasoned or subjected to aeration for at least thirty days before leaving the works.

(7) All tests shall be made at the expense of the contractor, and all cement or other rejected material must be immediately removed from the job and the vicinity.

Aggregates.—5.—(1) Extreme care shall be exercised in selecting the aggregate for mortar and concrete and careful tests must be made where any doubt exists of the materials for the purpose of determining their qualities and the grading necessary to secure maximum density or a minimum percentage of voids.

(2) Fine aggregates shall be uniformly graded from coarse to fine and consist of sand, crushed stone or gravel screenings, passing when dry, a screen having one-quarter inch diameter holes, and not more than six per cent. passing a sieve having 100 meshes per lineal inch. It shall be of clean silicious material free from vegetable loam and other deleterious matter.

(3) Mortars composed of one part Portland cement and three parts fine aggregate, by weight, when made into briquettes, shall show a tensile strength of at least 70 per cent. of the strength of 1:3 mortar of the same consistency made with the same cement and standard Ottawa sand.

(4) Coarse aggregate shall consist of inert material such as crushed stone or screened gravel which is retained on a screen having one-quarter inch diameter holes. The particles shall be clean, hard, durable and free from dust or other deleterious material, and the maximum size shall pass in any direction through a one inch diameter ring. A graduation of the size of the particles from fine to coarse will be considered advantageous.

(5) Samples of all aggregates must be submitted to the inspector of buildings and his approval of them obtained before being used in any work.

Reinforcement.—6.—(1) All steel used for reinforcement shall be medium steel made by the open hearth process,

and be rolled from new billets. No re-rolled steel will be allowed. The steel shall have an ultimate tensile strength of not less than 60,000 pounds per square inch of net cross section, and an elastic limit of at least one-half of this ultimate strength, and for sizes up to ¾ inch in diameter shall bend cold 180 degrees around a diameter equal to the thickness of the piece tested without sign of fracture on the outside of bent portion.

(2) For sizes greater than ¾ of an inch in diameter it shall bend cold 180 degrees around twice its own diameter without sign of fracture on the outside, except in cases where all bends necessary in the construction are to be made hot, in which case the steel shall bend cold 90 degrees around its own diameter without sign of fracture.

(3) All material tested to destruction shall show a uniform silky fracture and all reinforcing steel shall be free from checks, cracks, flaws or other imperfections, also free from paint, oil, dirt, grease or heavy rust or scale.

(4) If deformed bars are used only the net section—the section exclusive of all projections—of the area of such bars shall be considered effective.

(5) Tests of the steel proposed to be or being used in any reinforced concrete structure shall be made at the expense of the contractor upon the request of the inspector of buildings, and such tests shall be made at a place satisfactory to him and under the supervision and direction of the architect, engineer or superintendent in charge of the work.

(6) A certified copy of the report of all such tests to be filed with the inspector of buildings immediately after being made.

Mixing.—7.—(1) The ingredients of concrete shall be thoroughly mixed dry after which the proper amount of water shall be added and the mixing continued until the cement is properly distributed and the mass uniform in color and homogeneous.

(2) Methods of measurement of the proportions of the various ingredients, including water, in each batch shall be used which will secure separate uniform measurements at all times. The use of boxes especially constructed for the purpose will be preferred, but the use of iron wheelbarrows may, with the consent of the inspector of buildings, be used for measuring stone and sand.

(3) All concrete materials shall be measured loose.

(4) All concrete must be machine mixed using a batch mixer of an approved design if the amount of concrete in the work exceeds fifty (50) cubic yards. Continuous mixing machines will not be allowed.

(5) A competent foreman must be in constant attendance at the mixer to give his approval of every batch which leaves the machine.

(6) When the amount of concrete does not exceed fifty (50) cubic yards, the mixing may be done by hand on a smooth watertight platform not less than fourteen feet by twelve feet square, and having a raised rim around the edge at least three inches in height. The fine aggregate shall be first evenly spread on this platform and the proper proportion of cement shall then be spread over the aggregate when the ingredients shall be thoroughly mixed with hoes or shovels, then spread out evenly over the platform while in a dry state. Clean water shall then be applied and the cement and fine aggregate thoroughly mixed until a mortar of the proper consistency is formed which shall be evenly spread over the platform. The stone or gravel after being wetted shall then be evenly spread over the mortar and the whole mass thoroughly mixed with shovels and hoes by being turned over and worked at least three times, not counting the shovelling off the platform. No more than three-quarters of a cubic yard shall be mixed in any one batch.

(7) The materials must be mixed wet enough to produce a concrete of such consistency as will flow into the forms and about the metal reinforcement and which at the same time can be conveyed from the mixer or platforms to the forms without separation of the coarse aggregate from the mortar.

(8) Retempering mortar or concrete, i.e., remixing with water after it has partially set, will not be permitted.

Placing Concrete.—8.—(1) Concrete shall be deposited in the forms as rapidly as possible after leaving the mixer, and under no circumstances shall concrete be used that has attained initial set before final placing, nor shall such concrete be returned to the mixer.

(2) When placing concrete is once started it shall, if possible, be carried on as a continuous operation until pouring of the section or panel is completed.

(3) When being deposited or poured the concrete shall be agitated continuously with suitable tools such as a straight shovel or slicing tool kept moving up and down until all the ingredients have settled to their proper place by gravity, and the surplus water has been forced to the surface. Filling the forms completely and puddling afterwards will not be permitted. In placing the concrete the work shall be so laid out that the partly set concrete shall not be subjected to shocks from men hauling or wheeling material over it.

(4) Before placing concrete care should be taken to see that the forms are constructed as hereinbefore specified for and thoroughly wetted, and the space to be occupied by the concrete free from debris.

(5) When the placing of concrete is suspended all necessary grooves for joining future work shall be made before the concrete has had time to set. When work is resumed concrete previously placed shall be roughened, thoroughly cleansed of foreign material and laitance, drenched and slushed with a mortar consisting of one part Portland cement and not more than two parts of fine aggregate.

(6) Care must be taken to stop work at such a point that the joint formed when the work is resumed will have the least possible effect on the strength of the structure. Footings shall be cast to their full depth at one operation.

(7) Construction joints in beams and girders shall be vertical and at a point midway between supports, unless a beam is located at this point, in which case the joint shall be offset at a distance equal to twice the width of the beam.

(8) Construction joints in slabs shall be near the centre of the span. No joint will be allowed between slab and beam or girder.

(9) Any concrete which may run past the bulkheads must be cleaned up and removed before the concreting of the next section is started.

(10) Where brackets are used the brackets will be considered a part of the beam or girder.

(11) All columns are to be poured a sufficient length of time ahead of the floor construction to allow the concrete in the column to properly set up. The pouring of a column must be in one continuous operation to the bottom of the beam or girder is supports and during the pouring the concrete shall be well stirred or puddled with a long rod or tamp to expel all bubbles of air and prevent voids and honeycombing. Joints in columns shall be perpendicular to the axis of the column.

(12) In slab construction the finish must be laid integrally with the rest of the slab or it will not be considered as part of the slab in calculating the strength of same.

(13) Whenever possible the edges of girders, beams and columns shall be chamfered and the sides of beams and

girders splayed in order that the forms may be more easily removed.

(14) All reinforcing steel shall be accurately located in the forms and secured against displacement and the lateral spacing of the steel in lintels, beams or girders shall not be less than two and one-half diameters centre to centre.

(15) No concrete shall be poured until the engineer or superintendent in charge has examined the particular section in which it is desired to proceed with this portion of the work and has expressed himself satisfied with the structural condition and cleanliness of the forms and the placing, splicing and fastening in its proper position of the steel reinforcement.

(16) When concreting is carried on in freezing weather, the material must be heated and such provisions made that the concrete can be put in place without freezing. The use of frozen, lumpy sand or stone depending on hot water used in mixing to thaw it out will not be permitted.

(17) All concrete shall be kept at a temperature above freezing until it has thoroughly hardened, and all concrete which is frozen shall be removed.

(18) Concrete placed in warm weather, or which from any other cause is exposed to premature drying, shall be kept thoroughly wet during the first week after being put in place.

(19) Concrete shall not be placed in water unless unavoidable, but when this cannot be avoided, unusual care must be exercised to prevent the cement from being floated away, also the formation of laitance. The concrete shall also be deposited through a metallic tube or from a bucket having a bottom dump, and care shall be taken to keep the suiface of the concrete as nearly horizontal as possible. The proportion of cement in concrete deposited under water. shall be 25 per cent. in excess of that required for similar work deposited in the ordinary way.

Removal of Forms.—9.—(1) Forms shall not be removed until the concrete is thoroughly set and is of sufficient strength to carry its own weight together with whatever live load is liable to come on the construction.

(2) No form shall be removed without the approval of the architect or engineer or the superintendent in charge of the structure.

(3) The original supports for beams and girders must remain in place for at least twenty-one days after the concrete has been poured and before these supports are interfered with, the entire forms must be removed from supporting columns and the sides of beams and girders stripped so as to enable a thorough examination of the concrete to be made.

(4) The form shall not be removed from columns in less than six days, and forms supporting floor slabs shall not be removed in less than ten days after the concrete has been poured. The sides of forms for beams and girders may be removed at the same time as the forms supporting the floor slabs.

General Assumptions.—10.—(1) As a basis for calculations for the strength of reinforced concrete construction the following assumptions shall be made:

(a) A plane section before bending remains plane after bending.

(b) The modulus of elasticity of concrete in compression within the usual limit of working stresses is constant.

(c) In making calculations the tensile stress of concrete shall not be considered.

(d) The steel shall take all the tensile stresses.

(e) Perfect adhesion is assumed between concrete and reinforcement. Under compressive stresses the two materials are, therefore, stressed in proportion to their moduli of elasticity and their distance from the neutral axis.

(f) The ratio of the modulus of elasticity of steel to the modulus of elasticity of concrete shall be assumed to be fifteen for concrete with a crushing strength of 2,000 pounds per square inch after hardening for 28 days.

(g) Initial stress in the reinforcement due to contraction or expansion in the concrete may be neglected.

(2) The span length of beams and slabs shall be taken as the distance from centre to centre of supports, but shall not be taken to exceed the clear span plus the depth of the beam or slab. Brackets shall not be considered as reducing the span.

(3) The dead load shall include the weight of the structure and all fixed loads and forces.

(4) The live load shall include all loads and forces which are variable.

(5) The weight of reinforced concrete shall be taken as 150 pounds per cubic foot.

Bending Moments.—11.—(1) The bending moment for slabs and beams, when not continuous over supports, shall be taken at not less than $\frac{WL}{8}$.

(2) When slabs and beams are built continous over two or more supports, the bending moment shall be taken at not less than $\frac{WL}{10}$.

(3) When slabs and beams are continuous over one support only, the bending moment shall be taken at not less than $\frac{WL}{9}$.

(4) In the case of square panels reinforced in both directions and continuous over all supports, the bending moment of the slab shall be taken at not less than $\frac{WL}{20}$ provided, however, that when square floor slabs reinforced in both directions are continuous to walls, the bending moment of the slab shall be taken at not less than $\frac{WL}{18}$.

W = Total uniformly distributed load.

L = Span of beam or slab.

(5) The length of a slab in which reinforcement in both directions will be allowed for is limited to one and a half times the width. The proportion of load on a slab up to this limit which will be considered as being transferred to the side and end supports will be that obtained by using the following formulas:

(a) Load on longer supports $= \frac{L^4}{L^4 + B^4}$

(b) Load on shorter supports $= \frac{B^4}{L^4 + B^4}$

L = Length of span of slab.

B = Breadth of span of slab.

(6) The amount of reinforcing steel may be gradually reduced to seventy-five per cent. of that calculated per foot in width, commencing at the quarter point and continuing to the support. The reinforcement spanning the shortest direction shall be placed below the reinforcement spanning the longer direction.

(To be continued).

ENGINEERS' LIBRARY

Any book reviewed in these columns may be obtained through the Book Department of The Canadian Engineer.

BOOK REVIEWS.

Reinforced Concrete Buildings. By Ernest L. Ransome and Alexis Saurbrey. Published by the McGraw Hill Book Company, New York. Cloth, 6¼ × 9½ inches, 235 pages, 176 text figures. Price $2.50 net.

The authors of this volume are the president and chief engineer of the Ransome Engineering Company of New York. So many books on reinforced concrete of the stereotyped form have come to hand recently that it is a pleasure to note one on the subject of a different kind. The book covers the salient features of the design and construction of reinforced concrete buildings. The authors do not attempt to cover extraneous matter, but confirm themselves strictly to the subject in hand. The question of elementary structural theory and design is not taken up, but the authors treat the subject from the point of view of the experienced engineer. This is an advantage, for it allows of an expansion on features which make it most useful to the designer; on the other hand many books already exist which if necessary will furnish information with regard to earth pressures and the hundred and one other items included in the completed design. The book is divided into three parts, dealing respectively with the history of reinforced concrete, construction, the rational design of building and their practical construction. The history of reinforced concrete construction as narrated by Mr. Ransome is most interesting, and he is well qualified from his long connection with the methods used to deal with it. The part on design is a well arranged rational treatment of the subject. One serious criticism is to be noted, however, and that is that the authors have not seen fit to use the nomenclature now commonly used in connection with the theory of reinforced concrete.

The portion of the book devoted to practical construction is very good, taking up, as it does, materials of construction, floor systems, foundations, finishing operations, fireproofing, repairs, accidents, superintendents' specifications and the theory of beams as illustrated by texts. It must be said, however, that the personal part of both Mr. Ransome and Mr. Saurbrey obtrudes itself into the book far too much. Far too many references are made to Mr. Ransome's patents, work, etc., and Mr. Saurbrey's name might be left off many of the illustrations of finished work. The book forms a most valuable addition to the subject and should be in the library of every engineer interested in the design of reinforced concrete buildings.

Sewage Disposal. By George W. Fuller. Published by the McGraw-Hill Book Company, New York. Cloth, size 6 × 9 in., pp. 744, 80 illustrations. Price $6.00 net.

The announcement that a treatise on sewage disposal was being prepared by Mr. Fuller was made some time ago, and it was with more than ordinary interest that its appearance was awaited. Mr. Fuller's reputation in this field is too well known for any comment to be necessary as to his fitness for writing such a book. Now that the volume has been published we must say that the result is even beyond expectation. The book is an example of what a technical treatise should be. Among the numberless volumes now being presented to the engineering public it is refreshing to occasionally meet with one for which praise can be the only comment. The author with his intimate association of twenty-five years in the development of this branch of engineering science and his long experience in presenting clearly to his clients the purposes of the works he has designed, has eminently qualified him to write a book which is of equal service to the student of the subject and to the engineer of standing. Certainly, no one interested in the subject of sewage disposal should be without a copy. The author in the preface states the divisions into which the volume falls and while it is impossible in a short review to touch on all the features outlined, these divisions give a fair idea of the way in which the subject is taken up. The book is divided into four parts of approximately equal size. The first part is devoted to a very complete description of the composition of sewage, and the behavior of bacterial and biochemical processes in the decomposition of sewage. The importance of oxygen and deoxygenation not only as a means of measuring the strength of sewage but in the relation to proper conditions of the flow of sewage through collecting systems and various disposal devices, is discussed fully. The second part of the book is devoted to a recital of American experience in the disposal of sewage by dilution in inland streams, lakes, tidal estuaries and oceans. The limiting factors and conditions in present practice are described at length, with suitable summaries. The third part deals with the preparatory arrangements for the treatment of sewages. Descriptions are given of screening, settling tanks, septic tanks, chemical precipitation tanks, electrolytic treatment and strainers, with the present day practice with regard to each. The fourth part of the book deals with filtration matters with regard to present practice. The closing pages of the book are devoted to æration, sterilization and ozonization processes as they are now understood, with a few explanations as to institutional and residential plants, and a final comparative summary of general costs and efficiencies. The volume shows the results of an extraordinary amount of research not only in the technical press, but also in the gathering of data from existing plants. The treatise forms the most concise yet comprehensive text on the subject of sewage disposal which is in existence at the present time.

Suspension Bridges and Cantilevers.—Their Economic Proportions and Limiting Spans. By D. B. Steinman, C.E., Ph.D., Assistant Professor of Civil Engineering, University of Idaho. New York: D. Van Nostrand Co., Science Series. Boards, 4 × 6 inches. pp. 185, 1 plate. 50 cents.

Forty years ago Sir Benjamin Baker wrote an important monograph on "Long-Span Railway Bridges," in which he discussed and compared from the economic standpoint the types of bridges suitable for this class of construction. What was thus done for long-span bridge building in the materials then available has with equal effectiveness been done for present day conditions and materials by Professor Steinman in his readable little book just issued as one of the Van Nostrand Science Series.

The purpose of the writing is declared by the author to be the furnishing of adequate data from which the limiting and ecomonic spans for suspension bridges and cantilevers might be deduced in any consideration of the relative adaptability of the two types to long-span bridge construction. To this end designs and estimates of weight and cost were prepared for suspension bridges of 1,500, 2,250 and 3,000 feet span, and for cantilever bridges of 1,000, 1,500 and 2,000 feet span. The author then proceeds to establish the maximum practicable span for each type, the maximum economic span and the span of equal cost for the two types. It is of interest, but of doubtful practical value, to learn that the theoretical maximum span for suspension bridges and cantilevers, or the spans at which they cease to be self-supporting, is 14,700 feet for the former and 5,600 feet for the latter. The maximum practicable span for suspension bridges is established as varying from 3,500 to 4,900 feet, depending upon the live load, while for the cantilever the maximum practicable span is shown to be from 2,000 to 3,000 feet. These maximum practicable spans, it is explained are the limiting spans to which it would be possible to build the bridges in question, altogether apart from the character of the undertaking as an investment. Where bridges are required to pay their own way and not become a charge on those who erect them, the limiting span for the suspension bridge is set at 3,170 feet and for the cantilever 2,700 feet. The range of economic usefulness for the cantilever is defined as from 1,670 feet to 2,700 feet, and for the suspension bridge from 1,670 feet to 3,170 feet, the span of equal cost being 1,670 feet.

Several subsidiary investigations of value are included in the book such as the determination of the economic riseratio for suspension bridges, the minimum depth of stiffening trusses for adequate rigidity, the economic depth of stiffening truss, etc. Tables giving data concerning a large number of notable suspension and cantilever bridges and bibliographies relating to the subject add to the usefulness of the book.

While the conclusions relating to the maximum practicable spans are necessarily based upon debatable hypotheses, the author has made a contribution of distinct value to the engineering profession.—C.R.Y.

Centrifugal Pumping Machinery. By C. G. de Laval. Published by McGraw Hill Book Company, New York. Cloth, size 6¼ × 9½ inches, 181 pages, 19 tables, 159 illustrations. Price $3.

The book deals with the theory and practice of centrifugal and turbine pumps. There are few treatises in the English language which go into the principles which govern the actual design. The theories of centrifugal pumps are analyses based on certain assumptions, and but few of these analyses are at present published in English. The writer in this book gives three different theories which give approximately the same result. The basis of the principle of one of these is that the motion of the particles of water throughout the space between the blades strictly follows those particles contiguous to the blades. Another assumes that the water enters the inner periphery of the wheel in a radial direction across the entire width of the wheel. Neither of these assumptions is true, but they afford the means of attacking the problems which would otherwise be impossible. Many descriptions of existing installations are given. The book might be improved by the omission of some of the photographs, as they only occupy valuable room. The book will be a valuable one to both the designer of centrifugal pumps and the engineer who wishes some accurate knowledge on efficiencies, etc.

Dredges and Dredging. By Charles Prelini. Published by the D. Van Nostrand Co., New York. Cloth, size 6 × 9 inches, 280 pages, 82 illustrations. Price $3.

Dredging is a subject of considerable importance in our commercial life. Many millions of dollars are invested in plants and outfits, and as a result of dredging work vessels of great tonnage can now use the harbors of the world in safety. This treatise is a valuable addition to literature on the subject. The volume is a history of dredging showing the various stages up to the present time. The book is divided into twenty-nine chapters, devoted to different aspects of the subject and the various problems incidental to the work. Chapters are devoted to soils and their characteristics, excavation of sub-aqueous rock, hints on selecting dredges for various work, the different types of dredges in use, the cost of operating dredges, and much other valuable data. Complete descriptions of the methods used on recent large works are given. The book will be found to be a most complete and valuable exposition of the subject. The only criticism we would offer is the fact that wood cuts have been used in place of half-tones and zincs.

Tunnel Shields and the Use of Compressed Air in Sub-Aqueous Work. By William Charles Copperthwaite. Published by Constable and Co., Ltd., London. Second edition, revised. Cloth, size 8 × 11½ inches, with 260 illustrations and diagrams. Price $8.25.

There are very few accounts in English of shield work in tunneling operations. The employment of a shield, with of without the aid of compressed air, is of English origin, and the length of a tunnel so constructed in Great Britain is many times greater than the total amount of similar work elsewhere, yet the subject is no where dealt with with any degree of fulness in English text books. In this volume a history of recent developments in shield work is given and a collection of a mass of information scattered through many publications and consequently difficult and troublesome of access, is here made available. The work is a most authoritative one, and should form part of the library of every engineer interested in the use of compressed air in sub-aqueous work. The whole field of tunnel work with the use of compressed air is covered most thoroughly, and the volume includes descriptions of tunneling methods used to date on all the great works in Europe and America.

Valuation of Public Utility Properties. By Henry Floy. Published by McGraw-Hill Book Co., New York. Cloth, size 6¼ × 9½ inches, 386 pages. Price $5.

The valuation of utility property is of such recent date that at the present time there exists no general practice or formulated theory of the subject. No comprehensive text book exists, although much important information relating to valuation work has been published in various papers. This is the first attempt to digest and compile this material. The author states that he has endeavored to digest the opinions, papers, discussions, reports of commissions, and court decisions relating to the subject, in so far as possible, and to present the summary of the best practice with typical examples thereof. His aim has been to indicate, if possible, the line along which theory and practice seemed likely to be standardized. It must be said that he has succeeded very well in his object and has presented a well-balanced, logical discussion of the subject. Approved methods of ascertaining values are given, and the examples of appraisals used are more or less historic, and have already helped to establish precedence of current practice.

A Manual of Civil Engineering Practice. By F. Knowles Taylor. Published by Charles Griffin and Co., London. Cloth, size 6¼ × 9 inches, 809 pages, including index, with 1,179 illustrations, including 35 folding plates. Price, $7 net.

The author states that the work has been specially arranged for the use of municipal and county engineers. The discussion includes among many other subjects the mechanics of engineering, design of structures in brick, stone, reinforced concrete, roads, electric tramways, bridges, river works and land drainage, hydraulics and pumping machinery, waterworks and sources of supply, sewage disposal, sanitation, refuse disposal, and a chapter on specifications. With the limitations of space imposed on the author, he does not attempt to deal fully with many of the above subjects. A great deal of valuable information, however, is contained in the volume, and the book will appeal to the whole civil engineering profession as well as to the municipal engineer. One criticism must be registered against the work and this is, no doubt, due to the lack of space, that is, the brief mathematical treatment in connection with the development of some of the formulæ, which tend rather towards empiricism. The book should form a most valuable reference volume when the engineer lacks the time to look up the more highly specialized text book.

Reinforced Concrete Design Simplified. By John C. Gammon. Published by Crosby, Lockwood and Sons. Cloth, 9½ × 11 inches, 116 pages. Price $3.

The engineer has more and more to deal with the design of reinforced concrete in connection with building and engineering work Its many advantages as a system of construction have made its introduction one of the most important advances in engineering lines in the past century. It seems most probable that its use will increase with time. In the design of reinforced concrete, however, much valuable time must be used in making computations, which often have to be repeated many times with an accompanying waste of energy. The author has compiled a number of tables and diagrams which give at a glance the values of the different variables. These diagrams cover all phases of reinforced concrete design. For instance, having the bending moment for a beam, by reference to one of the diagrams, the economical size, the limiting conditions, the area of steel, the size of member required, can all be determined at a glance. Diagrams are also included for determining the sheer reinforcement, the design of columns, and of T beams. The book is extremely well indexed with side tabs for quickly turning to any required place, and the use of the diagrams is extremely simple. This book should be well received by the reinforced concrete designer. In fact, we would say that is is almost indispensable.

The Principles of Specification and Agreement Writing. By C. R. Young. Published by The Canadian Engineer, Toronto. Paper, 6 × 9 in., 47 pp. Price 25 cents net.

This book is made up of a series of six articles published in The Canadian Engineer on "Specification and Agreement Writing." The subject matter, the preliminaries to the contract, the composition of an engineering contract, the legal essentials and the desirable characteristics of an engineering contract, subject matter of the specification, specific and general clauses, the agreement and practical suggestions. The treatment is logical and clearly reasoned. The book is a most concise exposition of this most important subject and should be in the hands of every engineer engaged in preparing specifications.

Elements of Engineering Estimating. By A. Suggate. Published by The Technical Publishing Company, London. Cloth, size 5 × 7 inches, 135 pages. Price 90 cents.

This little volume, a practical handbook for students, draughtsmen and engineers, so the author states, gives in a suggestive manner the methods of estimating on engineering work. The prices given throughout the book are, of course, of use to Canadians on account of the difference in labor costs. The remarks and suggestions on the general basis of making estimates are very good however, and will repay attention by engineers on this side of the water.

Drill Work, Methods and Cost. Issued by the Cyclone Drill Company, Orrville, Ohio. Cloth, size 7 × 10, 350 pages.

A great many of the troubles encountered by drill-men are due to lack of experience or ignorance of the subject. While in no sense a catalogue, it contains valuable data pertaining to the drilling of wells and kindred subjects compiled by R. R. Sanderson, sales manager of the Cyclone Drill Company. Instructions are given as completely as possible, covering drilling operations, beginning with the setting up of the drill step by step through all the operations necessary to complete wells and blast holes in various kinds of material. The book is being distributed among the customers of the company and those interested in the subject.

A Short Course in Graphic Statics. By W. L. Cathcart and J. I. Chaffee. Published by the D. Van Nostrand Company, New York. Cloth, size 5 × 7½ inches, 180 pages, 58 illustrations. Price $1.50.

The aim of the book is to provide students of mechanical engineering with a brief course in graphic statics. The treatment has been restricted to the properties and general uses of the force and equilibrium polygons, as the author assumes that this is sufficient for the solution of most of the problems met in practice by a mechanical engineer. Some little attention has been given to the stresses in girders, etc.

Practical Gyrostatic Balancing. By Herbert Chatley. Published by The Technical Publishing Co., Ltd., London. Cloth, size 5 × 7½ inches, 72 pages. Price 65c.

This book forms a small and inexpensive treatise on the subject of gyrostatic control. This piece of apparatus is becoming daily of more and more importance in connection with the question of the automatic balancing of all kinds of locomotives, vessels and air-craft. The book should prove useful to inventors and engineers who desire a working knowledge of its mechanism.

Treatise on Hydraulics. By Mansfield Merriman. Ninth edition. Published by John Wiley and Sons, New York. Canadian agents, Renouf and Co., Montreal. Cloth, 6¼ × 9½ in., pp. 565, 224 figures. $4 net.

Merriman's hydraulics, which in this volume has reached the ninth edition and thirty-seventh thousand, needs little comment other than to note the changes rendered necessary by the advances in the subject. The book is known by all engineers and has become a standard textbook on the subject. The book in this edition has been revised and reset in order to cover the advances of the last nine years since the eighth edition was issued. The new matter includes descriptions of hydraulic instruments, methods of measuring water, oblique weirs, submerged tubes, regulating devices for pipes, conduits, dams, backwater, rainfall, evaporation

and runoff. The tables of coefficients for orifices, weirs, pipes, conduits, and channels have been revised and extended so as to include the results of recent experiments. A change in the old arrangement of the tables is noted; instead of being collected at the end of the book they are now placed in the text in connection with the matter explaining them.

PUBLICATIONS RECEIVED.

American Railway Bridge and Building Association. Proceedings of the 21st Annual Convention, held at St. Louis, Mo., October 17-19, 1911. Published by the Association. C. A. Lichty, secretary, 226 W. Jackson Boulevard, Chicago, Ill.

Department of Public Works. The annual report of the Department of Public Works of the Province of Saskatchewan for the year 1911.

Progress of Steam Measurements. Report for the calendar year 1910, by P. M. Souder, C.E., Department of the Interior, Dominion of Canada.

Ottawa River Storage and Geodetic Levelling. Reports on the above, being Vol. 2 of the report of the Minister of Public Works, Dominion of Canada.

U. S. Government Specifications for Portland Cement. Circular of the Bureau of Standards No. 33. S. W. Stratton, director. Issued May 1st, 1912, by the Dept. of Commerce and Labor, U.S.

Report of Board of Commissioners, Toronto Waterworks, 1912. Report upon the existing waterworks system and upon an additional water supply for the city of Toronto, by the Consulting Board recently appointed.

Report of the Department of Mines, 1911. For the Province of Nova Scotia. Copies may be obtained from the Commissioner of Public Works and Mines, Halifax.

Sanitary District of Chicago. Being the papers relating to the application of the Sanitary District of Chicago for permission to divert 10,000 cubic feet of water per second from Lake Michigan. Issued by the Department of Marine and Fisheries, Canada.

An Investigation of the Coals of Canada with Reference to their Economic Qualities. In six volumes, by J. B. Porter and R. J. Durley, assisted by P. C. Dennis, E. Stansfield and a staff of special assistants. Vol. 1 issued by the Mines Branch, Department of Mines, Canada. Price $1.

Report on the Geology of the Area Along the T. and N. O. Railway (Ontario Government Railway). Trial line between Gowganda and Porcupine, by J. G. McMillan.

The Strength of Reinforced Concrete Beams. Being the results of tests of 333 beams. By Richard L. Humphrey and Louis H. Losse. No. 2 Technological Papers of the Bureau of Standards, Dept. of Commerce and Labor, U.S.

The Los Augeles Aqueduct. Sixth annual report of the Bureau of the Los Angeles Aqueduct. Wm. Mullholland, chief engineer, Los Angeles, 1911.

American Wood Preservers' Association. Report of the proceedings of the eighth annual meeting held at Chicago, Ill., Jan. 16-18, 1912. F. J. Angier, secretary-treasurer, Baltimore, Md.

U.S. Reclammation Service. The tenth annual report, 1910-1911. F. H. Newell, director, Department of the Interior, U.S.

Water Power Development in the United States. Report of the Commissioner of Corporations. Issued March 14th, 1912. Dept. of Commerce and Labor, Washington.

Year Book, 1911, Swedish Chamber of Commerce in London. Containing the fifth annual general report of the Council, London, E.C.

Waterworks Efficiency. Bulletin of the Milwaukee Bureau of Economy and Efficiency. On the present capacity and future requirements. By F. E. Turneaure, Milwaukee, Wis.

Massachusetts Institute of Technology. Contributions from the Sanitary Research Laboratory and the Sewage Experiment Station. Vol. 8, issued by the Dept. of Biology and Public Health, Massachusetts Institute of Technology, Boston. Price $1.

The Present State of Development of Large Steam Turbines. By A. G. Christie. Being a re-print from the journal of the American Society of Mechanical Engineers.

Practical Road Engineering. For the New Traffic Requirements. Compiled from the special "Roads" issues of the "Surveyor" and "Municipal and County Engineer," by H. Percy Boulnois. The St. Bride's Press, Ltd., London.

Mechanical Engineer's Price Book, 1912. Edited by Geoffrey Brooks. Issued by E. and F. N. Spon, Ltd., London.

A Model Erection Shop is the title of a very artistic 16-page booklet just issued by Lockwood, Greene and Co., architects and engineers for industrial plants, 93 Federal St., Boston. It describes with illustrations the construction of a one-storey, reinforced concrete, sawtooth roofed machine shop which is unusually well lighted, and at the same time has its floor area covered by an abundance of cranes running on concrete girders. The booklet will be sent on request to Lockwood, Greene and Co., 93 Federal St., Boston.

CATALOGUES RECEIVED.

The Morrison Water Tube Boiler. Circular No. 1, describing boiler recently patented in the United States and Canada. Copies of pamphlets may be obtained from Egbert R. Morrison, general sales agent, Sharon, Pa.

Concrete Mixers. Circular issued by The Cement Tile Machinery Co., Waterloo, Iowa, describing their small batch concrete mixers.

Machinery and Supplies. Catalogue No. 42, illustrating machinery and supplies for the mining man. Mussens, Limited, Montreal.

Road Machinery. Pamphlet issued by The Barron and Cole Company, Barron Bldg., New York City, illustrating different types of road machinery manufactured by them.

Electrical Wires and Cables. Catalogue and hand-book bound in red morocco, illustrating electrical wires and cables manufactured by The Canada Wire and Cable Company, Limited, Toronto, Canada.

Sewage Appliances. Book issued by Tuke and Bell, Limited, sewage specialists, London, E.C., illustrating different types of sewage sprinklers, distributors, sewage installation, air compressors, flushing syphons, etc.

Rock Drills. Pamphlet issued by McKierman-Terry Drill Co., 115 Broadway, New York, illustrating their "Wizard" rock drills.

Manganese Steel. The Taylor Iron and Steel Co., Highbridge, N.J., forward pamphlet describing their "Tisco" manganese steel crusher, hammers, screen plates, etc.

Steam Pumps. Catalogue No. 8 of the Smart-Turner Machine Co., Ltd., Hamilton, illustrating different types of pumps manufactured by them.

Continuous Reinforced Concrete Pipe. The Lock-Joint Pipe Co., 165 Broadway, New York, forward their latest catalogue on concrete pipe constructed under the Meriweather system. A very artistic catalogue showing a number of recent installations of the pipe.

Waterworks Specialty. The Waterworks Equipment Co., 50 Church St., New York, present catalogue illustrating special types of hydraulic apparatus. Copies may be obtained by addressing the company.

Alternating Current Generators. Pamphlet No. 13b, issued by Pruce Peebles and Co., Ltd., of Edinburgh, illustrating Peebles medium and slow speed alternators.

Machine Tools for Heavy Work. The Wiener Machinery Company, 50 Church St., New York, representatives for the United States and Canada of Ernst Schiess, of Dusseldorf, Germany, forward catalogue illustrating different types of heavy machine tools, turning lays, boring mills, planing and milling machines, etc.

Steel Forms and Centering. The Standardized Steel Form Company, Niagara Falls, Ont., forward pamphlet illustrating the Blayney Collapsible and telescoping system of steel forms and centering for plain or reinforced, seamless, concrete pipe. Copies may be obtained by addressing the Standardized Steel Form Company, Niagara Falls, Ont.

Hydraulic Benders is the title of a new and interesting 64 page 6 in. by 9 in. catalogue devoted exclusively to hydraulic machines just published by The Watson-Stillman Co., 50 Church St., New York. Free copy will be mailed to interested parties requesting Catalogue No. 83.

CLAYS AND CLAY INDUSTRIES OF EDMONTON DISTRICT.

The Edmonton Board of Trade some months ago requested Professor Orton, an authority on clay and clay industries, to make a report on the possibilities in that direction in the Edmonton district. Professor Orton was asked to report upon the following points:—

1. Are the clay industries now established at or near Edmonton producing from their available material as good products as is practicable from the material they are using?

2. Are there other clay materials in the neighborhood available for the production of different and more valuable products than are now being made, and if so, what are the possibilities?

In answering the first question, Professor Orton states that two distinct classes of material are now being used here, consisting of (a) the glacial clays of the upper levels, and (b) the deposits on the river flats, composed of the silt deposited by the river in eddies and quiet spots and left by receding floods.

In regard to the material under class (a), the report seems to indicate that these materials present certain difficulties not commonly met with in other districts where the industries have attained considerable development. The report states that "the strata being worked showed the typical faults of glacial clay beds, viz., lack of continuity in character. They were shifting and changing in proportions of sand from day to day, and the problem of the pit foreman, to keep a reasonably fixed proportion of both clay and sand going up in each car load, is not an easy one, and will require constant vigilance. The quality of the body produced by this mixture of tough and sandy material, as evidenced by the kilns of brick standing burnt and ready for shipment, as well as by the waste piles and bats lying about, is fairly good for common building brick. It is not in any sense a fine material, but it makes a fairly good, strong and serviceable common brick. There seems no likelihood of making any materially different or materially improved product from this clay."

The report indicates that the material in class (b), that is to say, the river silt deposited on the river flats, presents even greater difficulties. The report states that these clays are alike in one respect, namely, they are all very treacherous and difficult to dry without cracking. The upper brown layer, worked alone, would make a fairly tough, plastic paste, and would work well in the machinery, but it would give prohibitive trouble in drying. The use of the sandy and silty layers is absolutely imperative to weaken it, to get sound or unchecked bricks. On the other hand, the sand and silt is of itself too weak and friable to make a brick, and is equally fatal to the quality of the burnt product, if allowed to get too high in amount. The manufacturers are, therefore, between two horns of a dilemma—cracking on the one hand, and weak, crumbly, worthless product on the other.

To quote the report: "If by constant vigilance the proportions can be kept inside the proper limits, the product will be a somewhat pale red brick of rather low, but sufficient strength, which, when in position in a building, will doubtless give good service.

"The possibility of improving the brick as to its hardness, strength and color by use of other processes than those employed has been considered. I cannot hold out any hopes of any important improvement in these respects."

In regard to the second point on which Professor Orton was asked to report, the results of his investigations indicate that there are possibilities of very important development. These occur in connection with the stratified shale and clay of an earlier formation than the glacial deposits or river silt now being used.

An exhaustive series of tests was made on samples of shales and fire clays taken from the various mines in the vicinity and from points along the river bank where the original stratified shales were exposed. While these materials present difficulties which do not occur in the clay deposits of Ohio, Pennsylvania, and other portions of the continent where clay industries have reached large proportions, it appears to be the opinion of Professor Orton that these difficulties are not insuperable, and that the profitable production of other and more valuable products, such as certain forms of tile and terra cotta and vitrified products, is commercially possible.

The project is rendered difficult by the somewhat abnormal character of these clays and shales. They show peculiarly sticky and soapy characteristics, which render them hard to work in the moulds; and they also show an abnormal percentage of shrinkage in drying, resulting in an amount of cracking, rendering the products useless. By an exhaustive series of experiments Professor Orton has demonstrated that treatment can be devised which will overcome these difficulties. While such treatment will materially increase the expense of manufacture, the cost is not considered by any means prohibitive, in view of the cost now entailed in bringing such products from present sources of supply. It is not practicable to enter into details of the elaborate experiments conducted by Professor Orton along these lines, and parties interested are advised to study the full report in the secretary's hands.

Professor Orton concludes his report as follows: "To utilize the Edmonton shales and fire clays is a proposition that should not be undertaken by any person or corporation who have not considerable financial resources, and who have the courage to use them. It is highly likely that a considerable period of expensive and costly experimenting would have to be made before a plant could be adjusted to do on a large scale what has been demonstrated on a small scale in the foregoing tests. On the other hand, a firm that has the money and intelligence to take up and solve this problem along the lines here laid down will, in my opinion, be able to produce vitrified clay products of at least fair quality at a cost far below that at which the goods can be brought in either from Vancouver or Ontario, or the nearest American clay-working centres."

ENGINEERING NOTES.

Galt, Ont.—Mr. W. H. Breithaupt, C.E., of Berlin, Ont., explained his proposed system of storage dams, to prevent disaster from excessive water in the Grand River, before a largely attended meeting of the board of trade. In a clear manner the speaker explained the reasons for flood conditions and the feasibility of a scheme for holding back a large portion of the water, thus reducing the danger of damage to property and providing a reservoir from which the water could be supplied in the summer months to maint in a reasonably good flow and provide continuous water power.

Montreal, P.Q.—Civic Controller Ainey has proposed a new scheme for the elimination of the level crossings of the Grand Trunk Railway within the limits of this city.

Mr. Ainey proposes to build tunnels under thirteen of the streets where these crossings are situated, devoting the two million dollars, which the city is being asked to contribute toward the cost of elevating the tracks, for this purpose.

He claims his scheme will save $1,000,000 in the expenditure for this work.

PERSONALS.

MR. CHAS. MOOGK has received the appointment of city engineer for the municipality of Waterloo, Ont.

MR. JOHN O'NEILL has been appointed to the position of municipal engineer for the city of Fredericton, New Brunswick.

MR. ANDREW BASHFORTH has been appointed general manager of the Provincial Steel Company, Limited, Cobourg, Ont.

MR. R. H. LEE, engineer for the municipality of Kamloops, British Columbia, has tendered his resignation to the civic authorities.

MR. GREGORY FEENEY has been appointed to a position on the engineering staff of the St. John & Quebec Railway Company.

MR. JAMES RUDDICK has been appointed to the position of general construction engineer for the Dominion Coal Company at Glace Bay, Nova Scotia.

CHIEF ENGINEER BRUCE, of the Dominion Government service on the final location of the second section of the Hudson Bay Railway, has resigned his position.

MR. JOHN L. FEENEY has retired from the office of engineer for the municipality of Fredericton, N.B., and will take a position in the Dominion Engineering Department in the city of St. John, N.B.

MR. FRANK E. STERNS will be on the engineering staff of the new Welland Canal, and will devote his energies to the matter of lock design. He is a Canadian and a graduate of McGill University.

MR. MORRIS F. G. WILSON, an English authority on drydock construction, arrived in Ottawa May 24th, and will act for the government in the selection of a suitable site for the proposed Quebec drydock.

MR. GROVER KEITH, formerly of Sussex, who has been on the staff at the St. John & Quebec Railway Company's offices, has been appointed to a residency on the line between Fredericton and Gagetown, N.B.

MR. R. C. HARRIS has been appointed to the position of works commissioner for the city of oronto. In addition to the duties accompanying this office he will be supervisor of the cleaning of streets and the disposal of garbage.

MR. E. W. RICHARDS, head of the stores and purchasing department of the Toronto hydro-electric department, has been appointed to the position of appraiser in the customs department of the Dominion Government.

MR. WALTER H. FLYNN has been appointed to the position of superintendent of motive power on the lines of the Michigan Central Railway. Mr. Flynn, previous to this appointment, was master mechanic of the same company.

MR. R. G. SNEATH, C.E., a graduate of Toronto University, has been appointed to the position of resident engineer on the installation of the sewage disposal plant for the municipality of Melfort, Saskatchewan, for Messrs. McArthur and Murphy.

JACOBS & DAVIES, Inc., have opened their Montreal office in the Eastern Townships Bank Building, 263 St. James Street, for the practice of general consulting and construction engineering, which business will be under the management of Mr. Paul Seurot, their representative in Canada.

MR. W. S. HARVEY, A.M., Inst. C.E., chief assistant engineer for the city of Lethbridge, Alta., has just been elected an associate member of the Canadian Society of Civil Engineers. Prior to coming to Canada in 1910 Mr. Harvey was in charge of the sewerage and general engineering work for the city of Plymouth, England.

MR. J. J. TAYLOR, who has lately been engaged on the Gibson and Minto line, has been appointed inspecting engineer for the Federal Government on the St. John Valley Railway, and will enter upon his new duties at an early date. Mr. Taylor was in charge of part of the preliminary survey work on the Valley Railway for the Provincial Government some time ago.

Mr. J. B. CHALIES, B.A.Sc., graduate of the University of Toronto, has been appointed superintendent of the new water-power branch of the Department of the Interior, which was originally under the Railway and Swamp Lands branch of the Department. The new water-power branch will make surveys of all the water-powers of Canada and gather data on stream fall.

CAPTAIN L. A. DEMERS has been appointed to the position of harbor master of the port of Montreal. Captain Demers is a native of Montreal, having been born in that city August 18th, 1862. He was educated in St. Mary's Academy and holds a commercial certificate from that institution. In 1878 he became an apprentice on a sailing vessel, and in 1886 was made mate; his final examination as master was passed in 1889. For some time he has been Dominion wreck commissioner.

MEETINGS.

Montreal, P.Q.—The Montreal Electrical Society, which has arranged a somewhat ambitious programme for the coming summer season, held a most important meeting Tuesday evening last at the Fraser Institute Hall. The primary object of this new society appeals to the younger members of the electrical industry, as it fills a want long felt, with the opportunity for local electrical men, young and old, to meet, exchange views, and take advantage of professional papers to be read by some of Canada's leading electrical engineers. With a membership approaching the two hundred mark, this new society appears to have made a good start. As the society will pay several visits to neighboring power plants, accompanied by classified engineers, the benefit to the younger members is easily seen.

MEETING OF AMERICAN SOCIETY OF ENGINEER DRAFTSMEN.

The regular monthly meeting of the American Society of Engineer Draftsmen, held on May 16th, in the Engineering Societies' Building, was marked by the admission to junior membership of Miss Marie Oberlander, a student of architectural drawing at Teachers College, Columbia University. Miss Oberlander is the first woman to be elected as a member of this organization.

The guest of the evening was Mr. F. F. Nickel. M.E., consulting engineer to the Worthington Pump Co., who delivered a very interesting and instructive lecture on "Practical Application of the Slide Rule."

A paper by Mr. R. E. Boehck, a member of the society, of Evansville, Ind., on "The Development of Logging Machinery," was read and discussed.

COMING MEETINGS.

FOURTH NATIONAL CONFERENCE ON CITY PLANNING.—May 27th-29th. Meeting, Public Library, Boston, Mass. Sec'y, Flavel Shurtleff, 19 Congress Street, Boston, Mass.

AMERICAN WATER WORKS ASSOCIATION.—June 3rd 8th. Annual Convention at Louisville, Ky. Secy., J. M. Diven, 271 River St., Troy, N.Y.

CANADIAN ELECTRICAL ASSOCIATION.—June 19th-21st. Annual meeting at Ottawa, Ont. Sec'y, T. S. Young, 220 King St. West, Toronto, Ont.

SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION.—June 26th-28th. Annual meeting at Boston, Mass. Sec'y, H. H. Norris, Cornell University, Ithica, N.Y.

ONTARIO MUNICIPAL ASSOCIATION.—Annual convention will be held in the City Hall, Toronto, on June 18th and 19th, 1912. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ont.

THE UNION OF CANADIAN MUNICIPALITIES.—August 27, 28 and 29. Meeting at City Hall, Windsor, Ont. Hon. Secretary-Treasurer, W. D. Lighthall, K.C.

CANADIAN PUBLIC HEALTH ASSOCIATION.—Second Annual Meeting to be held in Toronto, Sept. 16, 17 and 18.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE: Secretary. Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, S. J. Chapleau, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings,

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving; Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, C. E. Cartwright; Secretary, W. Alan, Kennedy; Headquarters: McGill University College, Vancouver.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1290.

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydonejack; Meets every first and third Friday of each month, October to April, in University of Manitoba, Winnipeg.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION.—President, Chas. Hopewell, Mayor, Ottawa; Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm. Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, W. Sanford Evans, Mayor of Winnipeg; Hon. Secretary-Treasurer, W. D. Lighthall, K.C., Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, Mayor Mitchell, Calgary.; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALTIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang; Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, N. W. Ryerson, Niagara Falls; Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewit, General Manager Consumers' Gas Company, Toronto; J. Keillor, Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President, J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, D. McDonald, Manager, Montreal Street Railway; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, Killaly Gamble, 703 Temple Building, Toronto.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, J. E. Ganier, No. 5. Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, F. S. Baker, F.R.I.B.A., Toronto, Ont.; Hon. Secretary, Alcide Chausse, No. 5. Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman; Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, J. P. McRae; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Wm. Pierce, Calgary; Secretary-Treasurer, John T. Hall, Brandon, Man.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, 115 Phœnix Block, Winnipeg, Man. Second Monday, except June, July and August, at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc. Printed forms for the purpose will be furnished upon application.

PLANS AND SPECIFICATIONS ON FILE.

The following Plans (P.) and Specifications (S.) are on file for reference only unless otherwise noted at the office of The Canadian Engineer, 62 Church Street, Toronto:—

Bids close		Noted in issue of
5-29—Water works, sewerage and electric light systems, Melfort, Sask.	(P. & S.)	5-2
6-10—Electrical equipment, Vernon, B.C.	(S.)	5-16
6-17—Electric Generating Station Equipment, Bassano, Alta.	(S.)	5-30
6-10—Cement sidewalks, Maple Creek, Sask.	(P & S.)	5-30

(Melfort plans and specifications are also on file at The Canadian Engineer Offices, 820 Union Bank Building, Winnipeg, and B33, Board of Trade Building, Montreal).

(Vernon specifications are on file at The Canadian Engineer Offices, Winnipeg and Montreal; Mather, Yuill & Company, Limited, Consulting Engineers, Vancouver, B.C.)

(Bassano specifications also on file at the office of The Canadian Engineer, Montreal)

(Maple Creek plans and specifications on file at The Canadian Engineer Office, Winnipeg, Man.)

TENDERS PENDING.

In Addition to Those in this Issue.

Further information may be had from the issues of The Canadian Engineer referred to.

TENDERS.

Amherst, N.S.—Tenders will be received up to Monday, June 3rd, 1912, for the following work:—Digging trench, depth ordered by Engineer, laying and caulking cast-iron water pipe, and backfilling trench, on six streets in the town of Amherst, N.S. Specifications and all other information may be obtained at the office of W. F. Donkin, Town Clerk, Amherst, N.S.

Bassano, Alta.—The time for receiving tenders for electric generating station equipment has been extended until June 17th. Specifications at the offices of The Canadian Engineer, Toronto and Montreal. (See advt. in The Canadian Engineer).

Calgary, Alta.—Tenders will be received until June 3rd, 1912, for the erection and completion of combined police and fire stations for the city of Calgary. Plans, specifications and full particulars at the office of the architects, Messrs. Lang and Major, Suite 11, Board of Trade Building. J. M. Miller, city clerk, Calgary.

Edmonton, Alta.—Tenders will be received up to noon of June 10th, 1912, for the ornamental iron and stair work required in connection with the new court house at Calgary. Specifications, plans, etc., may be had at the Structural Engineer's office, new Parliament Buildings, Edmonton, or at the branch office of the Department of Public Works, Calgary. John Stocks, Deputy-Minister of Public Works, Edmonton, Alta.

Lethbridge, Alta.—Tenders for paving a number of lanes in concrete will be received up to noon of Friday, June 14th, 1912, by G. W. Robinson, secretary-treasurer. Plans and specifications may be obtained at the office of A. C. D. Blanchard, City Engineer, Lethbridge.

Maple Creek, Sask.—Tenders will be received up to June 10th, 1912, for the supplying of material and construction of approximately 7,000 yards of cement sidewalks in the town of Maple Creek. Plans and specifications can be seen at The Canadian Engineer office, 820 Union Bank Building, Winnipeg, and at the office of the secretary-treasurer, D. Paterson. (See advt. in The Canadian Engineer).

Moose Jaw, Sask.—Tenders for the supply and delivery of 50 ornamental light standards suitable for Tungsten lighting, will be received up to noon of June 14th, 1912, by the City Commissioners. Plans, etc., may be obtained from J. D. Peters, electrical superintendent, Moose Jaw.

Newmarket, Ont.—Tenders will be received by O. E. Tench, architect, up to the evening of June 15th, 1912, for the erection of a six-roomed Public school building in the town of Newmarket. Building to be of stone and brick, with artificial stone trimmings; flat roof; plumbing; warm air heating. Plans and specifications may be seen at the office of architect. Dr. C. H. R. Clark, Chairman of Board, Newmarket.

Oshawa, Ont.—Tenders will be received by the Town Engineer up to noon of June 8th, 1912, for the construction of 25,000 sq. ft., more or less, of cement concrete sidewalks. (See advt. in The Canadian Engineer). Frank Chappell, C.E., Town Engineer.

Ottawa, Ont.—The time for receiving the tenders for the construction of station and other buildings on the Transcontinental Railway is extended to noon of June 14, 1912. P. E. Ryan, secretary, the Commissioners of the Transcontinental; Railway, Ottawa. (See advt. in Canadian Engineer.)

Ottawa, Ont.—Tenders will be received by the Public Works Department, Ottawa, until June 4th, 1912, for dredging at Miramichi Bay, N.B. Combined specifications and form of tender can be obtained on application to the Secretary of the Department.

Ottawa, Ont.—The Department of Public Works will receive tenders until June 4th, 1912, for electric light wiring, fittings, etc., for the Post Office building, Port Hope, Ont. Plans and specifications to be seen on application to the caretaker of the building, Mr. Jas. Curtis, or to Mr. Thos. Hastings, Clerk of Works, Postal Station "F," Yonge Street, Toronto, and at the Department of Public Works, Ottawa.

Ottawa, Ont.—Tenders for the construction of a rifle range at Chatham, Ont., will be received by the Director of Contracts, Militia Headquarters, Ottawa, until noon of May 30th, 1912. Plans, etc., can be seen at the offices of the officer commanding the first division, London, Ont.; at the office of Lt.-Colonel J. S. Black, brigade major, 1st Infantry Brigade, Chatham, Ont.; and at the office of the director of engineer services, headquarters, Ottawa. Eugene Fiset, colonel, deputy minister, Dept. of Militia and Defence, Ottawa.

Ottawa, Ont.—Tenders will be received until July 2nd, 1912, for the erection of a number of buildings for Indians on Reserves No. 2, 3 and 4, Fort George, B.C. J. D. McLean, Asst. Deputy and Secretary, Department of Indian Affairs, Ottawa.

Saskatoon, Sask.—Tenders will be received up to noon of June 5th, 1912, for all trades required in the erection and completion of an hotel on Twentieth Street, Saskatoon, for R. J. Barry, Esq. Plans and specifications can be seen at the Builders' Exchange, Saskatoon; and at the offices of the architects, Thompson, Daniel & Colthurst, Central Chambers, Saskatoon.

St. Catharines, Ont.—Bulk or separate tenders will be received for the erection and completion of a Sunday School building for St. George's Church, St. Catharines, Ont., until June 10th, 1912. A. E. Nicholson, O.A.A., architect, 46 Queen Street, St. Catharines, Ont.

Tisdale, Sask.—Tenders for the various works and materials in connection with installing a system of storm water sewers in the village of Tisdale, will be received up to June 15th, 1912. Plans and specifications may be seen at the office of the Commissioner of Public Health, Regina; or at the office of the Secretary-Treasurer, W. E. Moore, Tisdale.

Toronto, Ont.—Tenders for the supply and delivery of coal and wood required for Government House, Parliament Buildings, Osgoode Hall, Normal and Model Schools, Toronto, and for the Normal Schools at Ottawa, London, Peterboro, Hamilton, Stratford, North Bay, the Institutions for the Deaf and Dumb, Belleville, and the Institution for the Blind, Brantford, for 12 months ending 30th June, 1913, will be received up to noon of June 4th, 1912. Forms of tender, etc., at the office of H. F. McNaughten, Secretary Department of Public Works, Toronto, Ontario.

Toronto, Ont.—Tenders for dredging Murray Canal will be received at the office of L. K. Jones, Secretary Department of Railways and Canals, Ottawa, until June 5th, 1912. Specifications, etc., can be seen at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa, and at the office of the resident engineer of the Ontario-St. Lawrence Canals, Cornwall.

Toronto, Ont.—Tenders for regulators will be received by the Secretary, Toronto Electric Commissioners, City Hall, Toronto, until noon of Wednesday, May 29th, 1912. Specifications may be seen and forms of tender obtained from the Toronto Hydro-Electric System, 31 William Street, Toronto. P. W. Ellis, chairman.

Toronto, Ont.—Tenders, whole or separate, will be received by the Secretary-Treasurer of the Board, until Friday noon, May 31st, 1912, for the several trades required in the erection of a new school building on Manning Avenue, enlargement of Pape Avenue School, and for heating and ventilation, plumbing and electrical work in the new Duke of Connaught School on Morley Avenue, also for sale of old buildings. Full particulars may be obtained at the offices of the Superintendent of Buildings, City Hall. W. W. Hodgson, chairman of committee; W. C. Wilkinson, secretary-treasurer.

Toronto, Ont.—Tenders for the construction of a concrete arch bridge over Copeland's Creek, between Concessions 13 and 14, Township of Tiny, County of Simcoe, and known as McConnell's Bridge; and also for a combined concrete slab bridge, dam and abutments at Lot 12, Concession 4, known as Gregg's Bridge, will be received until Saturday, June 8th, 1912. Plans and specifications at the office of Frank Barber, Esq., Civil Engineer, 57 Adelaide Street East, Toronto. (See advt. in The Canadian Engineer).

Toronto, Ont.—Tenders will be received by the Chairman of the Board of Control, City Hall, Toronto, up to noon of June 5th, 1912, for the construction of cribs for Princess Street Yard, also additions to retaining walls of the Weston Road viaduct. Specifications, etc., at the Department of Railways and Bridges, City Engineer's office, Toronto. G. R. Geary, (Mayor), Chairman, Board of Control. (See advt. in The Canadian Engineer).

Toronto, Ont.—Tenders will be received by the Chairman, Board of Control, City Hall, Toronto, up to noon of June 4th, for the construction of asphalt, bitulithic and concrete pavements, grading, concrete curbs, concrete walks, sewers, and steel pipe for a number of streets in the city of Toronto. Specifications and full particulars may be obtained at the office of the City Engineer, Toronto. G. R. Geary, (Mayor), Chairman, Board of Control.

Toronto, Ont.—Tenders will be received at the office of Frank Barber, Esq., Civil Engineer, 57 Adelaide Street East, Toronto, up to noon of June 8th, 1912, for the construction of a concrete abutment for a bridge, known as the Clubine Bridge on Yonge Street, in the County of York, about 1½ miles north of the town of Aurora. Plans, etc., at the office of the engineer. (See advt. in The Canadian Engineer).

Toronto, Ont.—Tenders for all trades in connection with midsummer repairs to the Separate schools for the S[illegible] School Board for the city of Toronto, will be received till 5 p.m., June 3rd, at the office of the Board, 24 Duke Street. Specifications, etc., at the office of the architect, Chas. J. Read, 404 Confederation Life Building, Toronto.

Vancouver, B.C.—Tenders will be received by Messrs. Mackenzie, Mann and Company, Ltd., Metropolitan Building, Vancouver, B.C., up till noon of July 8th, 1912, for the superstructures and substructures of ten bridges over the Fraser, Thompson, and North Thompson Rivers on that section of the Canadian Northern Pacific Railway between Port Mann and the Yellowhead Pass, Province of British Columbia. Detailed drawings, specifications, etc., may be obtained on or after June 5th, 1912, at the office of the Consulting Engineers, Waddell & Harrington, Winch Bldg., Vancouver, B.C. (See advt. in The Canadian Engineer).

Tarvia

Preserves Roads
Prevents Dust~

Mount Pleasant Cemetery, Toronto. Roads built with Tarvia X in 1909.

Two Years' Trial in Toronto

THE above roadway in Mount Pleasant Cemetery, Toronto, was built with "Tarvia X" in 1909. The photograph was taken in the fall of 1911 and gives a fair idea of the excellent condition of this road, after two years of travel.

In the background this road has a five per cent. grade and if ordinary macadam had been used the surface would be raveled and worn out long ago. The best demonstration of the success of Tarvia is that the Cemetery authorities, after two years, are going to use a great deal more of it, as the following letter from the Superintendent shows:

February 15th, 1912.

Dear Sirs:

I wish to let you know we will require "Tarvia X" to build about 6500 yds. of road this year about the end of July.

I may say that we are well pleased with our Tarvia roads. The first that were made in 1909 have stood the test of traffic and heavy loads up to 16 tons—the wagon wheels leaving no impression.

Where our roads have a 7% grade we find the Tarvia fills the bill; no washing, no dust, easy to sweep and clean in wet weather.

(Signed) W. H. FOORD, Supt.

Tarvia is a dense, viscid tar product of great adhesive power. When built into the road as a binder, it forms a matrix about the stone, keeps the stone in position and furnishes an element of plasticity which greatly prolongs the life of the macadam under heavy loads or automobile traffic. There are three grades for different types and conditions of roads.

Booklets regarding same free on request.

ST. JOHN, N.B. HALIFAX, N.S.

CONTRACTS AWARDED.

Cobourg, Ont.—Messrs. McLaren and Co., 65 Cumberland Street, Toronto, have been awarded the contract to erect a sewage disposal works for the House of Refuge in this municipality.

Lethbridge, Alta.—Messrs. Smith Bros. and Wilson were the successful bidders on the tender to erect a manual training school. The building is to cost $35,150, not including the plumbing work. Other bidders were W. H. Holt at $35,750, and Hotson and Leader at $59,200.

London, Ont.—At a meeting of the Commissioners the Gartshore-Thomson Company, of Hamilton, was awarded the contract for supplying all the pipe at $35 a ton for special orders, and $31 a ton for pipe from 4 inches to 18 inches in diameter. Jenkins Bros., of Montreal, were given the contract for valves from 4 to 12 inches, the prices varying from $5.42 for the smallest to $35.63 for the largest. The tender of the London Foundry Company for the 18-inch valves at $150 was accepted.

Moose Jaw, Sask.—Messrs. Fielding and Shepley, St. Paul, Minn., U.S.A., have been awarded the contract for approximately 34,000 square yards of paving, their prices being:—

Fielding and Shepley, St. Paul.—3", 16 lb. treatment creosoted wood paving blocks, paving per square yard, $2.84; between tracks extra per square, 30c.; excavation per cubic yard, 65c. (Accepted.)

Alternative tender.—3½ blocks, paving, $3.10; between tracks, 30c.; excavation per cubic yard, 65c.

Other tenders received were as follows:—

Bitulithic and Contracting, Limited, Winnipeg.—Bitulithic paving 5" in thickness, paving (lanes excluded) per square yard, $2.90; between tracks per square yard, extra, 30c.; excavation per cubic yard, 70c.

R. Bangham, Windsor, Ont.—2½ asphalt block, paving per square yard, $3.44; between tracks per square yard, extra, 6c.; excavation per cubic yard, 50c.

Moose Jaw Paving Co., Moose Jaw.—16 lb. treatment creosoted blocks, paving per square yard, $2.94; between tracks per square yard extra, 65c.; excavation per cubic yard, 69c.

National Paving and Contracting Co., Winnipeg.—Sheet asphalt, paving per square yard, $2.60; asphaltic concrete, paving per square yard, $2.55; paving between tracks per square yard, 70c.; excavation per cubic yard, 75c. E. B. Bonnell, city clerk.

North Battleford, Sask. — The Canadian Westinghouse Company have received the contract calling for the supply and erection of a 500 kw. generator and equipment, the price being $5,580.

North Battleford, Sask.—Messrs. Laurie and Lamb have received the contract to erect and furnish a 750 hp. steam engine, the price being $20,250.

North Battleford, Sask.—The contract calling for the erection and supply of a boiler has been awarded to Messrs. Babcock and Wilcox, Ltd., the price being $8,700.

Point Grey, B.C.—A $1,500 contract for the supplying of galvanized piping for use in extending the water supply system of the municipality has been awarded to Messrs. Robertson and Godson of Vancouver.

Quebec, Que.—Messrs. M. P. and J. T. Davis, contractors, have the contract for the structural work in connection with the Quebec Bridge, and are present making preparation for the sinking of the caisson required for the building of the main pier.

The Dominion Steel Company have the contract for the superstructure of the bridge, and are extending and fitting up their shops at Lachine for the manufacture of the larger metal parts.

Saskatoon, Sask.—Messrs. R. J. Lecky Company, Limited, Regina, have been awarded the contract for the erection of the new Knox Church. The cost of the building is estimated at $129,000.

Saskatoon, Sask.—The contract for furnishing material for and construction of Superstructure 23rd Street Subway has been awarded to The Dominion Bridge Co., Ltd., their price being $12,188. Other bidders and their prices are: The Canadian Bridge Company, $15,200; The Canada Foundry Company, $11,520 (this tender did not include ties, waterproofing, brick or concrete covering); W. M. Scott, of Winnipeg, $13,400.

Saskatoon, Sask.—The contract for plumbing and heating in connection with the seven-story Ross Block to be erected on Third Avenue has been awarded to Thomson and Homer.

Saskatoon, Sask.—Messrs. Shannon Bros. & Cassidy secured the contract to build the new King George Hotel at a sum of $127,000.

The same firm also received the contract to build the new Westmount School. Both schools will contain fourteen rooms and will be of brick construction. Tenders other than the winning one on the King George School are: Smith Bros. and Wilson, $127,000; D. A. Black, $133,920; and Bigelow Bros., $137,700.

The tenders on the Westmount School including the winning tender of Shannon Bros. and Cassidy, are A. W. Bell, $114,000; Dinnie Construction Company, $119,000; Shannon Bros. and Cassidy, $128,395; Lyall Mitchell Company, $128,500; Smith Bros. and Wilson, $128,500; D. A. Black, $142,900; and Bigelow Bros., $149,800.

Thorold, Ont.—The contract for the erection of the Ontario Pulp and Paper Mills, Thorold's new million-dollar industry, was let to the Lackawanna Bridge Co., of Buffalo, and work will be started on the industry in the course of a couple of weeks. The mills, when completed, will manufacture news print paper exclusively. They will turn out from 120 to 130 tons every twenty-four hours.

The machines are to be the largest ever built, and are now well under construction by the Husey and Jones Company, of Wilmington, Del.

The mill will be operated entirely by electricity, requiring about ten thousand horse-power, which will be secured from the Ontario Power Company at Niagara Falls.

Winnipeg, Man.—St. John's College has let to Worsick Bros. the contract for the erection of a new college building at a cost of approximately $40,000.

RAILWAYS—STEAM AND ELECTRIC.

Province of Alberta.—At a meeting of the directors of the Alberta Central Railway held in Ottawa, the name was changed to the Dominion Central Railway owing to the fact that the road has now a Dominion charter.

Future plans of the road were discussed and it is the intention of the promoters to build a line north and south through Alberta connecting across the boundary with the Great Northern and Northern Pacific. The road will run along the slope of the mountains with feeders east and west.

Central Ontario.—The Lake Erie and Northern Railway project, with a line to Port Dover from Brantford, via Simcoe, and from Brantford to Galt via Paris, is now assured, providing by-laws carry in the various municipalities for debenture stock.

Hamilton, Ont.—A report has been presented to the municipal council dealing with the entrance of the Canadian Northern Railway to this city. The City Corporation did not look with favor on the proposed entrance and passed a resolution to that effect, but mentioned that an alternate route as proposed by City Engineer Macallum, might be adopted without resistance from the Corporation. This route leaves the line proposed by the company southerly of its intersection with the main line (London branch) of the Grand Trunk Railway and proceeds then across Cook's Paradise to the westerly side thereof, connecting with the Toronto, Hamilton and Buffalo Railway, near Main Street, crossing underneath the streets of the city as far easterly as Wentworth Street.

Toronto, Ont.—The municipal council have decided to spend the sum of $35,000 in obtaining a report on the best solution of the transportation problems of this city; also to appoint a railway expert for the legal department of the city. This latter appointment and the traffic experts are to be Canadians if suitable men apply for the positions.

Western Ontario.—A report states that the proposed electric line the Messrs. Mackenzie and Mann are contemplating building will come to Exeter via Stratford and St. Mary's, and from there go to Lake Huron. It is proposed to have the terminal on this lake located at Brand Bend.

LIGHT, HEAT AND POWER

Montreal, P.Q.—It is announced by the Montreal Light, Heat and Power Company, that beginning July 1st a further reduction in gas and electric rates will be effective. Gas will be sold at 95 cents per 1,000 cubic feet. The present price is $1. Electric lighting is to be seven cents per kilowatt hour as compared with 7½ cents at present.

Moose Jaw, Sask.—A report coming from Sask toon states that the power-house in Moose Jaw has been destroyed by fire, that the city is without electrical conveniences, and that there is a danger of the water supply failing.

District of Rainy River.—The Department of Public Works has ordered an investigation by departmental engineers of the water power situation along the Rainy River.

GARBAGE, SEWAGE AND WATER.

Bassano, Alberta.—At a meeting of the town council, May 6th, the John Galt Engineering Company of Winnipeg and Calgary were appointed engineers for the installation of a waterworks and sewerage system which will cost approximately $150,000. The by-law covering same will be voted on in the near future. A short description of this system will be found in our issue of March 21st, page 439.

Kincardine, Ont.—The Water and Light Commissioners of this municipality have decided to dispose of one steam pumping engine or exchange the same for a new pump.

Toronto, Ont.—The Toronto Board of Trade is not favorable to the city's acceptance, without further question, of the plan of the board of expert engineers calling for an eight million dollar expenditure on waterworks. They will recommend that the question of securing a perpetual supply from Georgian Bay be considered; also that the expert who installed a water system in California, bringing water for hundreds of miles, be engaged to make a report.

BUILDINGS AND INDUSTRIAL WORKS.

Crabtree Mills, P.Q.—Plans and specifications are being prepared for alterations and extensions and new dam for Messrs. E. Crabtree & Son, Limited, paper manufacturers, Crabtree Mills, P.Q.

Fort William, Ont.—The management of the Page-Hersey Company, who have taken over the agreement made between the Corporation and F. V. Samwell regarding a tube works, intend commencing construction operations on a plant in the course of a few weeks. The address of the Page-Hersey Company is Galt, Ont.

Magog, P.Q.—Plans and specifications are being prepared for a new weave shed, for the Dominion Textile Company, Limited, by T. Pringle & Son, Limited, Industrial engineers.

Medicine Hat, Alta.—Operations are to begin immediately on the erection of the new building for the Medicine Hat Milling Company.

Montreal, P.Q.—The firms and prices tendering on the erection of the new City Hall Annex, are as follows:—$649,000, made by the Peter Lyall & Sons Company, Limited; the next lowest being that of C. E. Deakin, $678,000, and the highest that of Mr. Joseph Bourque, $725,000.

Montreal, P.Q.—Plans and specifications are being prepared by T. Pringle & Son, Limited, Engineers, for extensions to reclaim plant for the Canadian Rubber Company, of Montreal, Limited.

Montreal, P.Q.—Plans and specifications are being prepared by T. Pringle & Son, Limited, Industrial Engineers, for a new slasher house for the Dominion Textile Company, Limited, Hochelaga Branch, Montreal.

Montreal, P.Q.—T. Pringle & Son, Limited, Industrial Engineers, are preparing plans and specifications for a manufacturing plant for "The N. K. Fairbank Company," Cote St. Paul, Montreal.

Moose Jaw, Sask.—Plans have been completed by Messrs. Reid & McAlpine, for the erection of a new building for the Young Women's Christian Association. The building will be three stories and basement, and of considerable size.

Nelson, B.C.—The management of the Dominion Saw Mill Company will erect a new mill on the site of the Yale-Columbia plant which was destroyed by fire last March.

Newcastle, N.B.—The municipal council are preparing to erect a new court house at an approximate cost of $31,000. Mr. Fairns is architect to this committee.

Ottawa, Ont.—The management of the Ottawa Gas Company are planning to increase the output of their plant by the erection of large subsidiary works. These works are to be placed on eight and one-half acres recently purchased by the company in the eastern part of the city.

Saskatoon, Sask.—The Winnipeg Paint & Glass Company are making preparations for the erection of a warehouse in this city. The new building will be metal clad 50-ft. x 100-ft. Mr. J. S. McDiarmid, Winnipeg, is interested in this matter.

Three Rivers, P.Q.—Plans and specifications are being prepared by T. Pringle & Son, Limited, Industrial Engineers, for a new cotton mill plant at the St. Maurice Valley Cotton Mills, Limited, at this point.

Toronto, Ont.—The Canadian Fairbanks-Morse Company, Limited, Toronto, are planning the erection of a large tractor shop on their property at Bloor Street West, Toronto. The plans and specifications for this building are being prepared by T. Pringle & Son, Limited, Industrial Engineers.

Welland, Ont.—The Cataract Rubber Company, Limited, has been incorporated with a capital stock of $250,000, and will locate its factory in Welland. The provisional directors are E. J. M. Block, of Buffalo; Jacob Dilcher, of Buffalo; and Myrtle A. Overholt, Col. L. C. Raymond and L. B. Spencer, of Welland. The company will manufacture rubber tires of all kinds and other rubber goods.

BRIDGES, ROADS AND PAVEMENTS.

Helena, Ont.—A steel bridge in course of erection on the line of the Grand Trunk Railway, collapsed. A break in a steel brace allowed a section of the structure to fall.

Ottawa, Ont.—There is a probability that Spark Street will be paved with asphalt during the coming season.

Orillia, Ont.—A petition calling for the paving of four blocks on the Main Street is receiving attention from the council. The cost of this work is estimated at $58,000.

York County, Ont.—A deputation from Pembroke, Ont., made an inspection of the work of the York County Commission for the purpose of securing first hand information on county road improvements to be placed before the ratepayers of Renfrew County in an attempt to encourage similar work in that division.

FIRES.

River St. Lawrence, P.Q.—The steamer "Iona," from Kingston to Montreal, was burnt and sunk in this river on May 18th last. The ship was loaded with soft coal and was owned by the F. E. Hall Company, of Montreal. The loss is estimated at $20,000.

St. John, N.B.—Messrs. Hutchings & Company, and Messrs. Patterson & Company had their plants destroyed by fire recently. The first-named company are bed and mattress manufacturers, the other engaged in the printing business.

TRADE ENQUIRIES.

The following were among the inquiries relating to Canadian trade received at the office of the High Commissioner for Canada, 17 Victoria Street, London, S.W., during the week ending May 13th, 1912:—

A London firm manufacturing chairs and tables make inquiry for the names of Canadian manufacturers of turned goods, suitable for common wood chairs, such as turned spindles, stretchers, chair seats, etc.; the firm are also in the market for supplies of Canadian beech.

A London firm manufacturing printing inks, litho colors, litho varnishes, relief stamping colors, relief stamping varnishes, etc., wish to appoint Canadian representatives.

A Scottish firm manufacturing breast drills, diaphragm pumps, semi-rotary pumps, and chucks for vertical machines and lathes, desire to get into touch with Canadian buyers.

THE TRIPLEX BLOCK

A Triplex Block hung from a temporary rigging and used for laying pipe.

What is the Life of a Triplex Block?

WE don't know. Triplex Blocks built by the Yale and Towne Co. at the very beginning—twenty-five years ago—are still in actual use. The Triplex Block of to-day possesses greater lasting powers. With its steel parts—its chain superior to any other—its non-wearing gear movement—and the guarantee of a rigorous test before shipment under a fifty per cent. overload. It will outlast the man who buys it, no matter how young he may be.

The Canadian Fairbanks-Morse Company

A Danish correspondent asks to be placed in touch with Canadian manufacturers of building materials open to do business with Denmark.

From the branch for City Trade Inquiries, 73 Basinghall Street, E.C.:—

A London firm who are buyers of old scrap copper, brass, gun metal, etc., would be glad to receive offers from Canadian exporters.

CURRENT NEWS.

Nelson, B.C.—A new powder magazine has recently been completed for the Giant Powder Company. It is constructed of fire and weather proof brick and concrete, and fitted with a complete system of lightning conductors and bullet proof steel doors, powder and cap magazines. An 800-ft. approach from the water and the railway to the buildings has also been constructed.

The powder magazine is 22 by 32 feet and the cap house is 8 by 10 feet in size. Each building has a double room, the inside filled with earth and the covering being of asbestos. Lightning conductors have been installed at all the corners of the buildings and doors, which are of 8-plate steel, and all other metallic work are electrically connected with these conductors. The magazine will accommodate between two and three carloads of powder. The cost of buildings and approach is in the neighborhood of $4,000.

Province of Quebec.—A great deal of field work will be done this coming season in geological and mining investigations in the Province of Quebec, by both the Dominion Department of Mines and the Provincial Mines Branch.

The following programme has been settled upon:—

The Dominion Geological Survey will send two exploring parties in North-western Quebec. One of these will investigate the mining possibilities of the country to the east of the Bell River, between Grand Lake Victoria and Lake Mattagami. The other party will operate along the Nottaway River, from Lake Mattagami northwards. This is along one of the most likely routes for the projected Montreal-James Bay railway.

Another Geological Survey party will continue the work begun two years ago in Brome and Mississquoi counties, mapping out in detail the geology of the region.

Mr. J. Keele, of the Federal Geological Survey, who has made a specialty of the investigation of the clay deposits and industry, will begin a scientific inventory of the clay and shale resources of the province. The importance of this work may be gathered from the fact that last year the value of the products of the clay industry of the province of Quebec exceeded $1,500,000. A large quantity of clay is imported from New Jersey for the manufacture of pottery, drain-pipe, glazed tiles, etc., and it is quite possible that this investigation may result in the discovery of clays suitable for these purposes in this province.

The Dominion Mines Branch will begin a study of the peat deposits, and will report on their suitability for fuel purposes. The province of Quebec, unfortunately, does not possess coal deposits and is dependent upon Nova Scotia and Pennsylvania for its supply of fuel.

The Quebec Mines Branch will send out two parties. One of these will investigate the mineral resources of the region of the head-waters of the Harricanaw River, in North-western Quebec, whence has come the rumor of important mineral discoveries. Another party will continue the inventory of iron resources, which was begun last year. These two parties will be respectively in charge of Dr. Bancroft, professor of Geology at McGill University, and Mr. E. Dulieux, professor of Mining Engineering at Polytechnic School of Laval University.

STREET RAILWAY ENGINEER WANTED.

The City of Brandon are calling for applications up to June 10th, for the position of Street Railway Engineer. Applicants for the position must have constructing and operating experience in street railways, and must be prepared, if necessary, to form a part of a public utility commission for the City of Brandon. The advertisement for the position will be found in this issue of The Canadian Engineer.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from The Canadian Engineer for small fee.

16435—May 3—Approving location of G.T.P. station to be erected at Fraser Lake, B.C., mileage 359 from Prince Rupert.

16436—April 23—Authorizing G.T.P. B.L. Co. to cross highway and divert road on its Cutknife Branch, Saskatchewan.

16437—May 2—Dismissing complaint of J. O. Hall, of Toronto, re G.T.R. train connection at Belleville for Madoc, Ont.

16438—May 2—Refusing application of C.P.R. to vary terms of Order 15777, Jan. 8th, 1912, re Goderich interchange.

16439—May 2—Dismissing application of Ontario Malleable Iron Co., Ltd., Oshawa, re C.N.O. Ry. spur for manufacturers.

16440-41—April 26—Approving by-law of Kootenay and Alberta Railway Co authorizing S. T. Maines, Traffic Manager, to prepare and issue tariffs of tolls and approving Standard Freight Tariff, C.R.C., No. 1.

16442—May 3—Extending for six months time for filing by Esquimalt & Nanaimo Ry. revised Standard Tariff of freight tolls.

16443—May 3—Authorizing Algoma Central & H. B. Ry. to construct branch line on Michipicoten Branch.

16444—May 2—Directing that C.P.R. protect Lansdowne Ave. crossing, Toronto, Ont., with gates within 30 days, 30 per cent. by city, 30 per cent. railway, 20 per cent. by Canada Foundry Co., and 20 per cent. from Railway Grade Crossing Fund.

16445—May 3—Authorizing C.P.R. to construct spur for Messrs. Skinner & Miquelon, Calgary, Alberta.

16446—May 4—Authorizing C.P.R., and approving location of station to be erected at Craven, Sask.

16447—May 6—Authorizing C.N.R. to connect its lines temporarily, during construction, with C.P.R. near Dalziel Station, in Twp. of Lyon, and Dist. of Thunder Bay.

16448—May 4—Approving plan "A" of G.T.R. crossing of Burford and Mount Pleasant Roads, near Brantford, Ont.

16449—May 1—Authorizing C.N.R. to cross with its Swift Current Extension 14 highways in Saskatchewan.

16450—May 6—Authorizing town of Welland to construct Major Street across G.T.R.

16451—May 3—Directing that C.N.R. pay cost of changes in interlocking plant near Ottawa, operating and maintaining to be divided equally among N.Y. & O.; C.P.R.; G.T.R.; C.N.R.

16452—May 6—Rescinding Order No. 15994, dated Feb. 17, 1912, and naming revision in express delivery and collection limits for Kamloops, B.C.

16453—May 6—Directing Railway Companies to charge certain rates on coke in carloads of 30,000 minimum, tariffs to become effective not later than June 1st, 1912.

16454—May 6—Approving revised location of Campbellford, Lake Ontario & Western (C.P.R., mileage 134.68 to 155.66.)

16455—May 7—Approving location of Niagara, Welland & Lake Erie Ry. between G.T.R. tracks on East Main St., Welland, and M.C.R. tracks on South Main St., same town, 1¼ miles.

16456—November 7—Authorizing C.N.O. Ry. to cross with its tracks the C.P.R. spur to Mimico, in Twp. of Etobicoke, interlocker to be installed; whole cost by C.N.O. Ry.

16457—May 7—Authorizing G.T.B. B.L. Co. to cross with its Calgary Branch 2 highways in Alberta.

16458—May 6—Approving location of 8 stations of G.T.P. B.L. Co. Biggar-Calgary Branch.

16459—May 6—Authorizing C.P.R. to re-construct bridge 83.2 and 79.1 on its London and Windsor S.D. Ontario Division.

16460—Authorizing C.P.R. to construct spur for Inland Coal and Coke Co., Ltd., at Merritt, B.C.

16461—May 7—Authorizing C.P.R. to use and operate bridges Nos. 2.6 and 10.6 on Crow's Nest Division.

16462—May 7—Approving location of Central Rly. Co. of Canada, from village of St. Eustache to village of Oka, mileage 16 to mileage 31, in County of Two Mountains, Que.

16463—May 7—Authorizing Campbellford, Lake Ont. & Western Ry. (C.P.R.) to cross with tracks at mileage 87.86 from Glen Tay over C.N.O. Ry. spur line in town of Trenton, Ont.

16464—May 7—Authorizing C.P.R. to construct its track across highway at mileage 5, Mission S.D., B.C.

16465—May 7—Authorizing C.P.R. to construct spur into premises of George Minger, at Titian, Alberta.

16466—May 7—Authorizing Central Vermont Ry. to make connection with C.P.R. spur line into Farnham Military Camp, Farnham, Que.

16467—May 7—Authorizing C.N.O. Ry. to cross Weston Plank Road, Toronto, by means of a subway.

16468—May 6—Naming express delivery and collection limits for Toronto, Ontario.

16469—May 6—Authorizing Thomas Davies, of Toronto, to construct over-head crossing over C.P.R., in Lot 6, Twp. of Nipigon, Dist. of Thunder Bay, Ont.

16470—May 9—Approving location of C.N.R. through Twps. 16-17, Range 26, west 2nd M., and part of city of Moose Jaw, Sask., mileage 84.25 to 87.13.

16471—May 4—Approving Campbellford, Lake Ont. & Western (C.P.R.) location, mileage 124.83 to 125.5, and revised location from mileage 127 to 134.68, Twp. of Hope, Ct. Durham, Ont.

16472—May 9—Authorizing C.P.R to cross with its Pheasant Hill Branch 19 highways in Manitoba.

16473-74—May 8—16475-76—May 9—Approving revised location of C.N.O. Ry. (Montreal-Port Arthur Line), through Twp. of Davis, Dist. of Nipissing, and of C.N.O. Ry. revised location at Callander, Twp. of Ferris, and Dist. of Nipissing; and of C.N.O. Ry. (Montreal-Port Arthur Line), through Twp. of Pedley, Dist. of North Bay; and C.N.O. Ry. (Sudbury-Port Arthur Line), through unsurveyed territory in District of Thunder Bay, mileage 149.85 to 161.03 from Port Arthur.

The Canadian Engineer

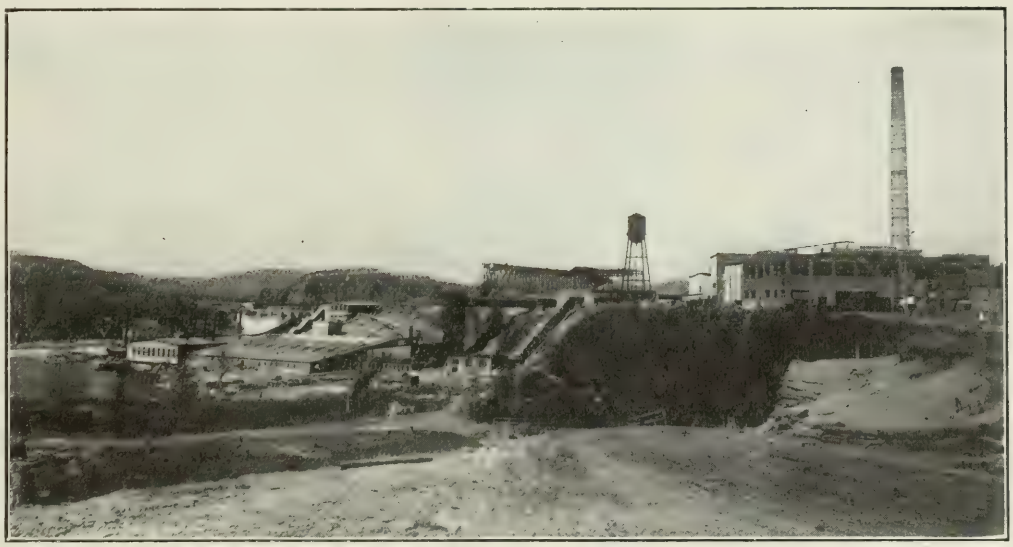
An Engineering Weekly

THE PLANT OF THE SPANISH RIVER PULP & PAPER MILLS LIMITED

The Spanish River Pulp & Paper Mills, Limited, are well located to meet the object they have in view. To Espanola, where are situated the company's mills, the Spanish River runs through the heart of the wood pulp country, its tributaries reaching practically every portion of the six thousand square miles comprised in the company's holdings.

Espanola is located on the Soo branch of the Canadian Pacific, forty miles west of Sudbury and 138 miles east of Sault Ste. Marie.

The company's timber lands consist of practically six thousand square miles, covered with the best grades of spruce and jack pine, balsam and poplar. The wood operations are carried on in the winter and in the spring; all the timber cut during the cold months is driven direct to the booming ground by means of the Spanish River, which, with its tributaries, drains the concession.



General View of Plant.

When the logs have been driven down the streams and rivers into proximity to the mills, provision has been made for their reception. At Espanola the Spanish River runs between two promontories. A sixty-foot head of water was obtained by placing a concrete dam across one branch. The penstocks lead away from this dam to the power-house, being controlled by gates operated by hand power, the mechanism being placed on the top of the dam. At one end a spillway is provided for getting rid of ice, logs, etc.

The manufacturing process commences when the logs first leave the booming ground. At this stage they vary in length from eight to sixteen feet. As they emerge from the booming ground the logs are raised on an inclined cable until they are on a level with a sixteen-foot slasher contained in a solid brick building far above the level of all the other buildings comprising the pulp plant. The slasher cuts all the logs into two-foot lengths. The dissevered logs, without any handling, drop directly from the slash table into a cable storage conveyor, which is six hundred feet long and sixty feet high. The wood, when it reaches the topmost altitude, drops into piles, where it remains until the time comes to feed the blocks into the barking machines. A supply has to be created to keep the mill going throughout the winter months, and there is a storage capacity for 40,000 cords of wood. The cost of taking the logs from the water, sawing them into two-foot lengths and storing them, is less than 15 cents a cord. This is the only saw slasher of its kind in use, as it was designed by the company's staff.

The logs are conveyed from the storage pile to a room situated on the brink of the hill overlooking the pulp mill proper. Here the rough knots and the bark are removed by means of barking machines operated by motor. The shavings and waste from the wood are mechanically conveyed by blowers to the boiler house. The barked wood, in its turn, is delivered to the grinder house by means of a short conveyor and a large gravity slide. At the bottom of this slide the logs find their way into a tank of water, where they remain until they are ready to be placed in the grinders.

The grinder room is situated in the northern part of the main pulp mill. Twenty-four grinders are in use and these are driven by water-wheels. When the logs have been reduced to the consistency of pulp, the pulp, greatly reduced in consistency by means of water, is conveyed to a large concrete tank by means of gravity. The grinders and water-wheels used in this process are set upon heavy concrete and steel foundations.

Over a period of five years, the maintenance of water-wheels and grinders has not exceeded fifteen cents per ton.

In the screen room the diluted pulp is conveyed by gravity through two sets of screens, passing thence in a

steady flow to storage tanks in the machine room. In the machine room there are eighteen 84-inch wet machines. The pulp flows in at one end of these in the consistency of milk, though the color is of a creamy shade, and re-appears at the other end in sheet form. These sheets are piled on iron trucks with wire mats between each sheet.

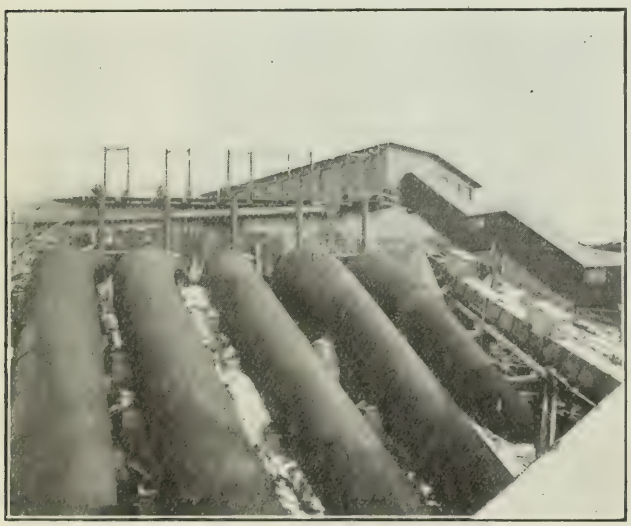
When the truck has been piled up to the height of several feet, it is rolled into one of the hydraulic presses, a pressure amounting to 450 tons being there applied. After the exertion of this pressure 58 per cent. of the pulp is dry. The pulp is then conveyed by means of an elevator to the upper level, where it is loaded into cars for shipment.

The pumping station contains two turbine water pumps, possessing a capacity of 6,000 gallons per minute. These pumps are used for supplying the paper plants with water. In addition are two turbine stock pumps, similar in capacity, which are used for pumping the ground woodpulp from the pulp mill on the lower level to the paper mill above. A booster pump is contained in the pumping station, electrically driven, which will be used for fire protection, and there is also a steam pump, to meet the requirements of the underwriters. with a capacity of 1,500 gallons per minute.

Pulp Mill, Showing Hydraulic Presses at Work.

The buildings comprising the new paper mill are all located so as to reduce the cost of manufacture, and the internal fittings are modern and complete. The filtration house has sufficient capacity to filter all the water to be used in both the pulp and paper mills. The water supply taken from the canal runs by gravity. A large freight elevator will be useful in the process of loading the company's output into cars. A storage building has been provided for the chemical pulp, a portoin of its basement to be used as a machine shop. The building containing the beater room has in its basement two ground woodpulp slush chests, on top of which are placed machines to abstract the water from the pulp, and to discharge the thick pulp into the chest ready for the beaters. Between the two chests mentioned are electrically driven pumps, which pump the thick pulp to the beaters above, thus eliminating any handling by labor.

In another portion of the building are found round concrete tanks, two of which are used to put the paper stock into and from the beaters, the whole being carried thence to the paper machines. In the basement are located two pumps, used to handle the paper stock from the tanks to the Jordan engines. The eight beating engines are in two units, and each unit is driven separately by a three hundred h.p. motor. On the second story are eight beaters, each of a capacity of one ton, and these are used to prepare the paper stock for the paper machines. The two large Jordan engines which are used to refine the paper stock after it has peen prepared by the beaters are directly connected to electric motors.



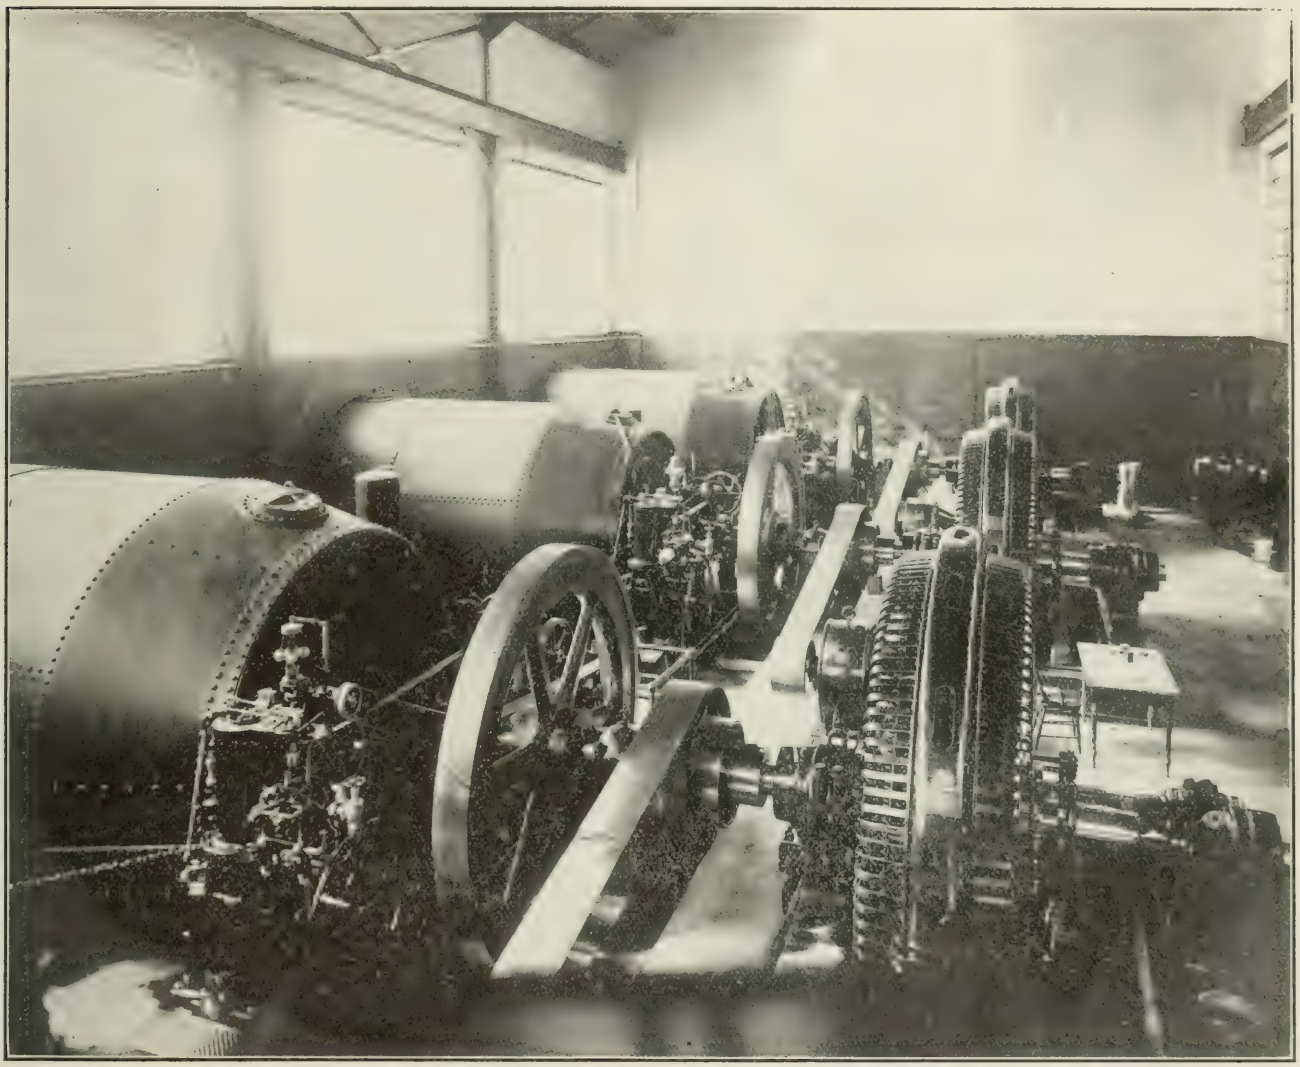
View Showing Penstocks with Gate Mechanisms Showing Above Dam.

Interior View of Paper Mill, Showing Two Paper Machines Installed.

The paper machinery is in the central building, which is 276 feet long by 82 feet wide. In the basement of this building are eight large suction pumps, two large stock pumps, and the necessary water pumps. To propel at variable speed the paper machines two six-hundred h.p. steam engines have been provided. The exhaust steam from these engines will be used to apply heat for the drying of the paper. In order to eliminate the handling of broken paper by labor, a beater has been placed in the basement, and after the broken paper has been treated it will be pumped once more into the stock tanks. On the second story are two Fourdrinier paper machines of the latest type. Each of these machines is capable of manufacturing a sheet of newspaper 156 inches wide, at 600 feet per minute. Each machine will have a capacity of 50 tons daily. At the north end of the machine room a gallery has been arranged, which contains four pneumatic save-alls. The water from the machines is pumped to these save-alls, and in this manner every particle of stock that the water contains is saved. A system has been arranged for the economic handling of the paper product from the machine to the finishing room.

The building in which the paper product is finished is 154 feet long and 92 feet wide. The upper story is used to finish the rolls of paper, while the lower story is designed exclusively for storage. Railroad tracks have been installed on each side of the building, with loading platforms designed for the economical loading of the paper into cars.

All the buildings connected with the paper plant are equipped with steel window frames, concrete window sills and steel lintels, with single and double glazing. The entire design of the buildings was considered with a view of installing two more paper machines at a later date, which, in view of the arrangements made, may be done at small expense. A steel water tank, 100 feet high, possessing a capacity of 50,000 gallons, has been erected, thus assuring the company in its operation a continuous supply of water pressure, as well as good sprinkling system in case of fire. Cast iron water mains have been laid round the entire plant, and a large number of hydrants, hose houses and reels have been provided, arrangements which have met with the entire approval of the Fire Underwriters.



General View of Interior of Power House, Showing Arrangement of Turbines and Generators.

The paper mill, now being completed, will give the company the following production:—

Newspaper	100 tons daily
Mechanical pulp	107 " "

Provision has been made so that the paper mill capacity can readily be doubled at minimum capital expenditure.

The hydraulic and steam power equipment will be described more fully in a succeeding article.

NEW BUILDING BY-LAW FOR TORONTO.

(Continued from last week.)

(7) In all cases where reduction in the bending moment is allowed on account of continuous action, sufficient steel reinforcement must be provided in the top of the slab or beam over the support to meet the requirements of the accepted theory of flexure, and this upper reinforcement shall extend on both sides a sufficient distance beyond the centre of the support to develop adhesion equal to at least the strength of the upper bars on the basis of the allowable unit stresses.

(8) If the girders, beams and slabs are poured in one continuous operation, then the girders or beams may be treated as T-beams with a portion of the slab acting as a flange. In no case shall the overhanging width on each side of the girder or beam exceed four times the thickness of the slab and the total width of the flange shall not exceed five times the width of the girder or beam.

(9) In beam and slab construction an effective metallic bond shall be provided at the junction of the beam and slab and where reinforced concrete girders carry reinforced beams, the portion of the floor slab acting as flange to the girder must be sufficiently reinforced with bars near the top, at right angles to the girder, to enable local loads to be transmitted directly instead of through the beams to the girder, thus avoiding an integration of compressive stresses due to simultaneous action as floor slab and girder flange.

(10) In the design of T-beams acting as continuous beams, due consideration shall be given to the compressive stresses at the support at the bottom of the beam.

(11) When the overall vertical distance of the tension members of a girder or beam is greater than one-sixth of the total depth of the girder or beam, the stresses in members shall be computed in proportion to the distance from the neutral axis.

(12) Shrinkage and thermal stresses must be provided for by the introduction of steel.

Proportion of Concrete and Allowable Stresses on Concrete and Steel.—12.—(1) All concrete for columns, girders, beams, slabs, walls, fireproofing or piles shall be composed of materials meeting the requirements of these regulations, and be mixed as hereinbefore specified, in the proportion of not less than one part of cement to two parts of fine aggregate and four parts of coarse aggregate, or in such other proportions as may be necessary to make the resistance of the mixture to crushing not less than two thousand (2,000) pounds per square inch after hardening for 28 days.

(2) Tests to determine this value must be made at the expense of the contractor when required by the inspector of buildings at a place and by a person satisfactory to him and under the direct supervision of either the said inspector of buildings or a person representing him.

(3) When the proportion of cement is increased and the quality of aggregates hereinbefore called for used, an increase may be made on the allowable working stresses proportional to the increase in compressive strength at 28 days as determined by actual tests, but this increase shall not exceed 25 per cent. On this basis the following maximum stresses for 1:2:4 concrete will be allowed in construction:

(a) Compression in extreme fibre of girders, beams and slabs, 600 pounds per square inch.

(b) Direct compression, 450 pounds per square inch.

(c) Shearing stress, when diagonal tension is not resisted by steel, 40 pounds per square inch.

(d) Shearing stress, when all diagonal tension is resisted by steel, not to exceed 100 pounds per square inch of effective cross section.

Members of web reinforcement shall be designed so as to adequately take up all involved stresses throughout their entire length. They shall not be spaced to exceed three-fourths of the depth of the beam in that portion where the web stresses exceed the allowable shearing value of the concrete.

Web reinforcement, unless rigidly attached, shall be placed at right angles to the axis of the beam and looped around the extreme tension member.

(e) For tee-beams the width of the stem only shall be used in calculating the shear.

(f) Adhesion to plain steel bars, 60 pounds per square inch of surface of bar.

(g) Adhesion to deformed steel bars, up to 100 pounds per square inch of surface of bar may be permitted.

(h) For compression in columns with not less than 1 per cent. and not more than 4 per cent. of longitudinal reinforcement, the safe load shall be computed as follows:

Safe load (in pounds) = 450 (Ac+15 As).

Ac = Net cross sectional effective bearing area of concrete in square inches.

As = Cross sectional area of longitudinal reinforcement in square inches.

(i) For columns reinforced with both longitudinal steel and spirally wound hooping when the volume of hooping is equal to at least one per cent. of the volume of the enclosed concrete and the longitudinal reinforcement is not less than one per cent. and not more than four per cent. of the cross sectional area, the safe load shall be computed as follows:

Safe load (in pounds) = 650 (Ac+15 As).

Ac = Net cross sectional area of concrete enclosed in hooping in square inches.

As = Cross sectional area of longitudinal reinforcement in square inches.

(4) The foregoing allowed stresses shall be used only where the unsupported length of the column is not greater than 15 times the least diameter of effective bearing area. Where the length exceeds this limit, the allowable stress shall be reduced according to approved standard formula.

(5) Bending stresses due to eccentric loads on columns shall be provided for by increasing the section of concrete or steel until the maximum stress on a column will not exceed the allowable working stress.

(6) The least diameter of effective bearing is to be understood to mean the distance from inside to inside of hooping in columns with spiral hooping, and in others from outside to outside of longitudinal reinforcement.

(7) The pitch of spiral reinforcement shall not be greater than one-sixth of the effective diameter of a column, and in no case more than three inches, and adequate means must be provided to hold it in place as as to form a column, the core of which will be straight and well centred.

(8) When columns are reinforced with longitudinal rods only, the reinforcement shall be tied together with bands, having an area of not less than one-sixteenth of a square inch, placed not more than the effective diameter of the column apart or in any case not more than twelve inches. The bands to be jointed in such a manner as to do away with any liability of the reinforcement spreading, and shall be wired to each longitudinal rod.

(9) The percentage of reinforcement in any column, regardless of the load carried by it, is not to be less than one per cent. of the effective cross sectional area. Reinforcement to be in all cases placed at corners of square or rectangular columns, the minimum size of which shall be 9/16 inch round or ½ inch square steel rods.

(10) No column shall have less than sixty-four square inches of effective area or a dimension of less than eight inches.

(11) When longitudinal reinforcing rods in columns have an area in excess of one and one-fourth square inches the ends shall be faced or milled off normal to the longitudinal axis and such rods shall have full and perfect bearings and a tight fitting sleeve or other approved appliance shall be provided at each joint to keep the rods in their proper position.

(11) When longitudinal reinforcing rods in columns have an area of less than one and one-fourth square inches the rods may be lapped and securely wired together, the splice to be of a sufficient length to develop by adhesion the strength of the rod.

(13) All butted joints shall be made at the floor levels or at points where the columns may be considered as fixed, and the centre of lapped joints shall not be more than one foot above floor levels or points at which rigid lateral support is afforded the columns. The ends of all rods at the base of columns shall be made smooth and right angled from the longitudinal axis and such rods shall have a perfect bearing on a steel plate or casting of sufficient size and strength to distribute the load which the column supports to such an extent that the allowable compressive stress per square inch on the material under this plate shall not be exceeded, or in lieu of the plate the stress may be distributed in concrete footings to the required extent by means of dowels of sufficient length and area to sustain the weight by adhesion of the concrete to the steel, without exceeding the specified limit for such in this regulation. The tops of all dowels to extend to the top of the footing and be made perfectly level and smooth to receive the longitudinal reinforcing rods and the joint between the dowels and the rods to be made with a pipe sleeve which is to be grouted into the footing at least six inches and extend six inches above the top of same and the reinforcing rods after being secured in their proper position are to be solidly grouted into the sleeve with liquid Portland cement.

(14) The area required in footings which have to support columns having both spiral hooping and vertical reinforcement shall be obtained in a similar manner to that immediately above specified for columns with vertical reinforcement only. The longitudinal reinforcing bars in all columns shall be straight and sufficient metallic lateral support shall be provided to keep them in their proper place until the concrete in the column has set.

(15) The allowable stress on steel in tension shall be sixteen thousand pounds (16,000) per square inch.

(16) Where it is necessary to introduce steel to resist compression in girders, beams or slabs, the compressive stress per square inch allowed on such steel shall not exceed fifteen times (15) the computed compressive stress in the concrete at the same distance from the neutral axis. All such steel shall be anchored into the mass of concrete in such a way as to prevent any possibility of buckling.

13.—The minimum protection for steel reinforcement which is to be taken, is the distance from the surface of the steel to the nearest concrete surface, shall be:

(a) For girders and columns, two inches.
(b) For beams and lintels, one inch and a half.
(c) For floor and roof slabs, one inch.

Plain and Reinforced Concrete Walls.—14.—(1) Concrete walls without reinforcement, other than those of foundation or basement, shall be constructed with concrete of the same composition and quality in all respects to that hereinbefore specified for reinforced concrete, and shall be the full thickness prescribed in this by-law for brick walls.

(2) Buildings having a complete skeleton construction of steel or of reinforced concrete construction of a combination of both, may have exterior walls of reinforced concrete at least eight inches thick; provided, however, that such walls shall support only their own weight, and that such walls shall have both vertical and horizontal steel reinforcement on both sides, the rods to be placed not more than eighteen inches apart from centres, and be securely wired together at each intersection and rigidly connected with columns and girders. All rods shall be lapped a sufficient length to develop their full stress by the allowable unit stress for adhesion. Additional rods shall be set around openings, the vertical ones to be wired to the nearest horizontal ones, and the horizontal rods at top and bottom of openings wired to the nearest vertical ones. In all cases the percentage of steel reinforcement to be provided shall be sufficient to enable the wall to safely resist a uniformly distributed horizontal pressure by thirty pounds per square foot acting on either side of it, but in no instance shall the percentage of reinforcing metal be less than one-quarter of one per cent. in each direction. The thickness of a reinforced concrete curtain wall shall not be less than one-eighteenth of the unsupported height.

Tile and Reinforced Concrete Joist Construction.—15.—(1) When tile and reinforced concrete joist construction is used for floors, the tile shall be sound, hard burned, free from shrinkage cracks, or uniform size and corrugated in a horizontal direction upon the sides.

(2) The reinforced concrete joists shall be parallel and in perfect line and of sufficient width to develop the steel, which steel is to be protected from fire with concrete of a similar mixture and thickness to that hereinbefore specified for concrete beams. Should concrete be required on the top of the tile to take compressive stress it must be not less than two inches in thickness and must be poured at the same time at the joists, and be of the same mixture. The tile shall be thoroughly soaked with water before the pouring of the concrete is commenced. In this class of construction the dead and entire live loads will be assumed to be carried by the reinforced concrete joists.

16.—Upon the completion of a reinforced concrete building the architect or engineer who designed the structure shall issue a signed certificate and have the same posted in a conspicuous place on each floor, stating the safe capacity per square foot of floor space, if the entire floor is designed to carry the same load. If, however, the floor is designed to carry different loads, each section must be provided with a certificate stating the capacity of that particular section and describing the limits thereof.

17.—Load tests shall be made by and at the expense of the contractor when required by the inspector of buildings, under his direction and in his presence or in the presence of his representative, on any portion of a reinforced concrete structure within a reasonable time after erection. Such tests shall show that the construction will sustain a load of twice the live load for which it was designed without causing any permanent deformation.

18.—No system of reinforced concrete shall be used which is not capable of design and investigation in accordance with the formula and principles laid down in these regulations.

19.—Section 111 of By-law No. 4861, being "A By-law for regulating the erection and to provide for the safety of buildings," is hereby repealed.

Comments by the Citizens' Committee.—While the proposed by-law for regulating reinforced concrete construction in the city of Toronto is in the main satisfactory to the Citizens' Committee on the revision of the building by-law, there

are certain provisions to which exception is taken. In the opinion of this committee these should be amended before the proposed ordinance becomes law, if it is to represent the latest and best constructional practice.

To this end the committee wishes to make the following comments on the draft by-law, and offers corresponding suggestions for its improvement.

Section 2, sub-section 3, page 2.—It would appear from this that the weekly reports furnished the inspector of buildings are to concern only the records of the progress of concreting and the date of removal of forms. In the opinion of the committee it should be required to include also a declaration that, in the opinion of the inspector in charge, the work covered by the report has been executed in all respects in accordance with the plans, specifications and city building regulations.

Section 5, sub-section 3, page 7.—It is now recommended by the best authorities that test mortars shall show, not merely 70 per cent., but 100 per cent. of the strength of a similar mortar made with standard Ottawa sand.

Section 6, page 8.—The complete prohibition of Bessemer steel, high elastic limit steel and re-rolled steel for reinforcement, is in the opinion of this committee not warranted. If these materials are capable of passing the usual tests prescribed for them, their use should be allowed. Suitable tests for high elastic limit steel should be inserted in the by-law.

Section 7, sub-section 3, page 10.—In the interests of definiteness the volume of a bag of cement should be defined, and the committee recommends that this be fixed at 9/10 of a cubic foot.

Section 8, sub-section 11, page 12.—The minimum length of time which columns should be poured ahead of the floors should be defined.

Section 11, page 16.—The bending moments for slabs and beams fixed by this section are in excess of those required to be figured in the newer building codes of large American cities. With the careful inspection provided for in the regulations under discussion, it would, in the opinion of this committee, be entirely safe to reduce these requirements to conform to those recently adopted by the cities of New York, Chicago, St. Louis, Minneapolis and San Francisco. It is therefore recommended that for slabs and beams continuous over two or more supports the moments at the centre and at the supports be taken as 1/12 wl. and that for slabs and beams continuous over one support only, the moments shall be 1/10 wl. Corresponding alterations should be made in sub-section (4) to cover slabs reinforced in both directions and in sub-section (7) to conform with the above rules

Section 11, sub-section 6, page 18.—The reduction of reinforcing steel in slabs here prescribed is not in accordance with accepted theory. It is recommended that the steel be reduced at the support to 50 per cent. of that calculated per foot of width and that the reduction begin at the third points instead of at the quarter points.

Section 11, sub-section 8, page 18.—Where the slab extends on only one side of the beam, it should be allowed to flange up to four times its thickness.

Section 11, sub-section 10, page 19.—It is almost universal practice to allow compressive stresses at the bottom of a beam at the support, fifteen per cent. in excess of those allowed elsewhere in the beam. This should be permitted in the present regulations.

Section 12, subsection 3, page 20.—The allowable working stresses prescribed in this sub-section are lower than those permitted in the most recently adopted building codes of American cities. It is recommended that the compression on the extreme fibre of slabs, beams and girders be 650 pounds per sq. in. The corresponding stress in the codes of New York, Chicago, St. Louis, Minneapolis and Cleveland runs from 650 to 800 pounds per sq. in. For direct compression, the specified stress of 450 pounds per sq. in. is also lower than is now generally adopted. It is recommended that this be placed at 500 pounds per sq. in., the same as permitted in New York, St. Louis, Cleveland and Baltimore. The formula for safe loads on columns, paragraph (h), should be correspondingly changed.

Section 12, sub-section 6, page 22.—It is excessively severe, and beyond the present requirements of the City Architect's department to allow as effective diameter of a longitudinally reinforced column only the distance from outside to outside of reinforcement. Were this rule adopted it would mean that a 10 inch by 10 inch column would have an effective area of only 36 sq. in., or 36 per cent. of its area. It is customary to allow the full area in this class of columns. Sub-section 10 on page 23 should be altered to read: "Sixty-four square inches, outside area."

Section 12, sub-section 8, page 22.—For bends in columns having longitudinal reinforcement only, one-quarter inch rounds should be permitted spaced not farther apart than the outside diameter of the column. Since such material is of the nature of wire, and therefore very easily worked, its use should be allowed, as tending to ease and rapidity of construction.

Section 12, sub-sections 11-13, page 23.—In sub-section 11, it should be made clear that the area of one and one-fourth square inches is of individual rods and not the aggregate area. For rods having an area less than this, it should be allowable to use a pipe-sleeve joint without milling the ends of the rods, as an alternative to the lapped splice prescribed. Shore columns require to be reinforced for moment due to wind, it should be allowable to locate the splices at other places than at the floor levels.

Section 13, sub-section 15, page 24.—There is no good reason why the use of high elastic limit steel should be prohibited. It should be allowed to be stressed up to one-third of the elastic limit, but not over 20,000 pounds per square inch.

Section 14, sub-section 2, page 25.—The amount of reinforcement here required is excessive. Steel enough to resist a pressure of 30 pounds per square foot on either face of the wall is all that is necessary.

Section 15, sub-section 1, page 26.—Provision should be here made for concrete tile or other fillers than terra-cotta tile.

Section 18, page 27.—This would technically debar the use of any new system of construction without amendment of the by-law and therefore should be omitted.

It is recommended that for definiteness and convenience the values of R in the equation $M = Rbd^2$ be listed in the by-law for working stresses from 16,000 to 20,000 pounds per square inch, as indicated in the memorial presented to you in May last, section 19, page 52. Further, it is requested that the moment area be defined as 0.87 times the distance from the top of the beam to the centre of the steel for both rectangular and T-beams.

OTTAWA WATER SUPPLY.

The Pitometer Company, who recently made a water survey for the city of Toronto, have been employed by the city of Ottawa to make an extensive survey of the water mains of that city. Investigations will begin at once and will probably cover six or eight weeks.

RECENT DEVELOPMENTS IN PAINT TECHNOLOGY.*

By Henry A. Gardner.†

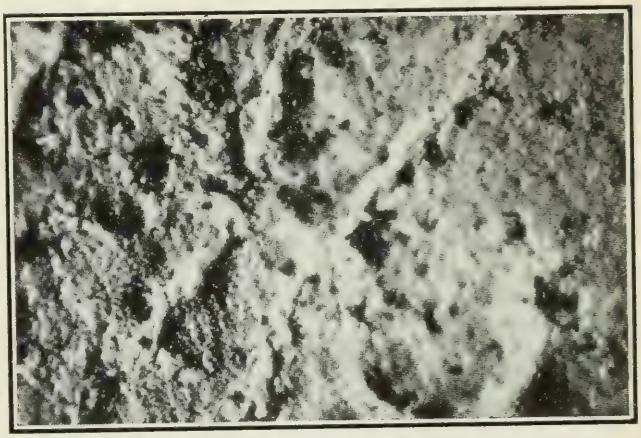
Lumber and Its Relation to Paints.—The proper choice and treatment of lumber is one of the most important problems which the builder as well as the painter has to face. When about to build a dwelling, barn, or other structure made principally of wood, the question is sure to arise in regard to what variety to select so as to get the maximum service and money value. The locality in which the structure is to be built must often have a bearing upon this question. While it is true that the painting of each type of wood demands the special consideration of the painter, it is also true that the study of paints for wood protection points toward the production of a paint that will give satisfactory results under all conditions and on all grades. It is the writer's opinion that a paint may be made that will be perfectly well suited for the preservation of every species of wood, provided the paint is properly treated in the hands of the skilful and intelligent painter, who can produce lasting results on almost every type, by varying the proportion of thinners and oil in the various coats. The painter who uses the same paint on soft pine and again on hard pine, without making a special study of how to reduce the priming coat for the hard pine, will be likely to get inferior results on the latter. In case of failure, the natural impulse is often to place the blame upon the paint, whereas the real responsibility may rest upon the painter's lack of knowledge.

Signs of Paint Failure.—Those who are responsible for the care and maintenance of property the familiar with the condition of surface presented by almost all wooden buildings or structures which have been improperly painted with inferior paints. "Chalking" or "flouring" are terms used to describe the condition of a paint surface which has deteriorated within the paint film. The formation of minute fissures generally spoken of as "checking," as well as the effects best described as cracking, scaling, peeling and blistering, are other signs of failure which cause paint coatings to present an unsightly appearance, and which point inevitably either to the use of improperly made paints or to improper application. The cause of these conditions is not difficult to understand when even a brief study of the character of the materials entering into the composition of a paint has been made. It is, however, a fortunate circumstance that the proper admixture of different types of pigments enables us to correct the strong tendency exhibited by special pigments to rapidly deteriorate in an oil film. This point will be more fully discussed in a later paragraph.

Requisites of a Good Paint.—Progressive manufacturers are aiming to produce a paint which will show, under the widest range of conditions, good hiding power, adhesiveness, freedom from internal strains, permanency of color, relatively high imperviousness to moisture, sufficient elasticity to prevent scaling or cracking when subjected to expansion or contraction, and freedom from the chemical action which results in deep checking or excessive chalking. Such a product as this cannot be obtained, in the writer's opinion, by the use of any one pigment in linseed oil. In order to meet all the demands as stated above, there should be in an economical and durable paint a proper percentage of the various pigments which, united, will tend to correct each other's faults, and thus produce a durable paint coating of maximum efficiency.

The Composition of Paints.—As is well known, a paint is a mixture of one or more pigments and a vehicle which acts the part of the spreading and binding medium. Up to the present time the vehicle portion of paints has generally been made of linseed oil, admixed with some volatile thinner, such as turpentine. The subject of oil and plant vehicles will be discussed more fully later on.

Physical Properties of Pigments.—The pigment portion of a paint for use on barns and farm buildings may, if desired, be composed of properly selected iron oxides or other colored pigments, even containing in some cases a moderately high percentage of silica, clay, or other inert materials, and give perfectly satisfactory results. For the preservation and decoration of dwellings, however, the pigment portion of paints is generally made as a whole or in part of the most expensive white pigments, such as white lead and zinc oxide. The relative values and properties of these white base pigments will now be taken up.



"Chalking."—Type of Decay Exhibited by Improperly Made Paint.

White Lead.—White lead, either of the corroded or sublimed type, is perhaps the most generally used of all the white pigments as a paint base. Corroded white lead is a basic carbonate of lead, while sublimed white lead is a basic sulphate of the same metal. Both of these types are white and admirably adapted as painting materials. They take relatively the same amount of oil and spread easily, producing paint films which are highly opaque and which, therefore, hide efficiently the surface upon which they are placed. Sublimed white lead is a relatively finer pigment than corroded white lead, and seems to show a tendency to chalk to a greater extent upon exposure to the weather. Corroded white lead is more alkaline, however, than sublimed white lead, and when used alone with linseed oil generally shows a tendency to chalk to a considerable extent in a short time and to show deep checking, thus permitting the admission of moisture. The alkaline nature of this pigment produces considerable action upon certain tinting colors and results in fading or darkening when mixed with delicate greens or blues.

The use of white lead has been condemned in some parts of this country, as well as abroad, because of its alleged poisonous properties. While it is true that lead poisoning may occasionally occur in some factories where the workman and his conditions are not properly safeguarded, it is, nevertheless, a fact that lead poisoning very seldom occurs among painters of experience and cleanly habits. Carelessness in mixing white lead is, fortunately, a practice almost obsolete among painters. The use of

---

*Paper delivered before American Institute of Architects.

†Assistant Director, Institute of Industrial Research, Washington, D.C.

paints already ground in oil by means of machinery to a pasty condition, allowing easy working and reducing, obviates the danger of lead poisoning from any such cause as this, even though the percentage of lead in such paints is in preponderance.

Zinc Pigments.—Another pigment which has proved itself of great value to the painter is zinc oxide. The use of this pigment may be said to have almost revolutionized the paint industry of the world, and its increased consumption during the last ten years is sufficient evidence of its value as a painting material. Zinc oxide is produced by oxidation and sublimation of zinc ores and is not only extremely fine, but of great whiteness. It has good hiding power, although not quite so great as that shown by the white leads. It tends to produce a glossy surface, making it especially valuable for use on interior work and in enamels. When used alone it has the effect of hardening the oil film in which it is enveloped, and upon long exposure causes cracking and scaling. However, when the sublimed or corroded white leads are properly combined with zinc oxide, a more durable surface is produced, the shortcomings of each pigment being overbalanced by the good properties of the other. The proper combining properties of zinc oxide with white lead may be said to vary between twenty to fifty-five per cent. of zinc oxide for paints designed for exterior use. In the opinion of the authors, lead and zinc

"Scaling."—Type of Decay Exhibited by Improperly Made Paint.

pigment in the above percentage, properly blended and ground, make paints of far better wearing value than can be produced with either white lead or zinc oxide used alone.

Zinc-Lead.—Zinc-lead, a pigment sublimed from mixed lead and zinc ores, and containing about equal proportions of zinc oxide and lead sulphate intimately combined, as well as leaded zinc, a product similarly produced, but with zinc oxide running about seventy-five per cent., are white base pigments of value which are used to a considerable extent. They are generally slightly off color, however, and are therefore used most largely in paints which are to be tinted in various colors.

Lithopone.—Lithopone, a pigment produced by precipitation, and consisting of zinc sulphide and barium sulphide, is of great value in the manufacture of interior paints. On account of its liability to darken and disintegrate, however, it is seldom used on exterior work, although recent tests have shown that when used in combination with zinc oxide and whiting, it gives very promising results.

Crystalline Pigments and Their Use.—Barytes (barium sulphate), silex (silica), whiting (calcium carbonate), gypsum (calcium sulphate), asbestine (silicate of magnesia), and china clay (silicate of alumina) are white crystalline pigments which, when ground in oil, become transparent. All of these pigments possess the property of strengthening a paint film made of white lead and zinc oxide, and often increase the durability of such a paint. Barytes, silica, and china clay are especially valuable for this purpose. Asbestine, because of its needle-like structure and low gravity, prevents settling and acts as a reinforcer of paint films. Whiting or calcium carbonate should be used when zinc oxide is in excess in a paint, so that the hardness of the paint may be overcome.

A white paint must be possessed of sufficient opacity to efficiently hide the surface upon which it is placed, when three coats are applied for new work or two coats for repainting work. Mixtures of the white leads and zinc oxide, with the latter pigment running not over fifty-five per cent., will easily produce such a result and wear well. It is generally deemed advisable, however, by most manufacturers to take advantage of the excessive opacity of such mixtures, which allows the introduction of moderate percentages of these inert pigments which give greater strength and other desirable features to a paint. The percentage of natural crystalline inert pigments to add to a white paint made of lead and zinc must, however, be moderate and insufficient to detract materially from the hiding power of the paint.

White-Paint Formulas.—From these conclusions, which have come from wide experience in the testing of paints under actual service conditions, there can be recommended to the buyer of paints and to the manufacturer and master painter those machine-mixed paints in white, made by reputable manufacturers, the composition of which will show a mixture of white lead and zinc oxide, with the latter pigment within limits of between fifteen to fifty-five per cent., and especially the same mixtures reinforced with the moderate percentage of crystalline inert pigments referred to above.

Tinted paints possess greater hiding power than white paints; and the above proportions would be somewhat changed for a tinted paint containing any percentage of coloring material. Tinted paints are, moreover, far more serviceable than white paints, as will be shown later.

Mill v. Paddle.—The mixtures under consideration should be ground in linseed oil by the manufacturer, through stone or steel mills, to a very fine condition, as it is only through proper grinding that the pigments can be properly blended. The mixing of paint by hand is, fortunately, to a large extent a thing of the past. The uneven lumping of hand-mixed paints is often the cause of their failure. Such ancient and crude practice should be avoided by every painter, for it is more economical to obtain semi-paste paints, properly ground by machinery, to such a condition that they may be easily broken up and tempered. Such paints may be reduced to the proper consistency with oil and volatile thinner for application to any kind of wood.

In the opinion of the writers, a majority of the paints sold by reputable dealers and made by reputable manufacturers in this country are not only made from the best linseed oil and highest grade pigments obtainable, but are put in a form ready for the painter to thin down with full oil or turpentine reductions, either for priming work or to be used without reductions for finishing coats. The large metropolitan painter who wishes to make his own tints and shades may, however, prefer to have his mixed pigment paint ground by the manufacturer in heavy paste form for certain purposes.

Results of Field Tests.—A careful analysis of the results of field tests which have been carried on in different parts of the country would be far too voluminous for insertion in this bulletin. The official findings of special com-

mittees of inspection have already been published in special reports. Whereas there may still remain ground for some difference of opinion in regard to the interpretation of the results obtained on the various test fences, there can be no doubt that considerable information of the highest value has been yielded both to the producers and consumers of paints. One of the principal results obtained from these tests has lead to the opinion expressed above by the writers, that better results can be obtained by a proper mixture of selected pigments than by the use of any one pigment in linseed oil. This conclusion has also been reached by engineers of the United States Navy, and, as a result, the specifications of the Bureau of Yards and Docks for paints made of straight white lead and oil have recently been changed to call for white lead combined with upward of fifty per cent. of zinc oxide. Many engineers and master painters have interpreted the results of the tests in the same way, and the attention of the authors has been called to a number of opinions which show that the tendency of demand among those who are properly informed is for a high grade combination type of paint rather than for any single pigment paint.

Color.—The selection of the color for a dwelling or other structure is a matter that depends largely upon the good judgment and taste of the owner, combined with the advice of the painter. One point, however, should be impressed upon the mind of both, namely, that practically all shades or tints made upon a good white paint base, through the use of permanent tinting colors, will better withstand exposure to the atmosphere than the white base used alone. Owing to the cheerful effect produced by the use of white paints on dwellings, a very large quantity of white will continue to be used. If these white paints are designed in line with the suggestions brought out above—that is to say, if the white lead bases are properly reinforced with zinc oxide and other pigmentary materials—better results will undoubtedly be obtained, as far as appearance and durability is concerned, than if white lead had been used alone. The consumer should remember, however, that more durable results will be obtained by the use of tinted paints.

Reductions and Thinners.—Turpentine, with its sweet odor, high solvent action, and wonderful oxidizing value, has always taken first place amont the volatile liquids used for thinning paints. Wood turpentines, produced from the steam distillation of fine-cut fat pinewood or from the destructive distillation of stumpage and sawdust, have been refined in some cases, by elimination of odor and toxic effects, to such purity that they are equally as good as the purest grades of gum turpentine, and their use is bound to increase in the paint industry.

The painter and manufacturer have come to understand that certain grades of asphaltum and paraffine distillates are equally as satisfactory as turpentine for use in paints for exterior purposes. Those volatile oils which are distilled from crude oil with either a paraffine or asphaltum base and possessed of boiling point, color and evaporative value approximating similar constants of turpentine, are excellently suited to partly, and in some cases wholly, replace turpentine in exterior paints. A little additional dryer added to paints thinned with these materials will cause oxidation to take place in the proper time.

Prominent master painters* have shown that benzol, a product obtained from the distillation of coal tar, differing from benzine, a product obtained from the distillation of petroleum, is a valuable thinner to use in the reduction of paints for the priming of resinous lumber such as cypress and yellow pitch pine. The penetrating and solvent value of benzol is high, and it often furnishes a unison between paint and wood that is a prime foundation to subsequent coatings, preventing the usual scaling and sap exudations which often appear on a painted surface. Because of the great solvent action of benzol, however, this material should never be used in the second and third coatings. These facts will doubtless interest the southern painter, who has so much wood of a refractory nature to paint.

Oils.—The increasing cost of linseed oil has raised the interesting question as to whether or not it is a good practice to use an admixture of other oils in connection with it, in high-grade paint coatings. Strong differences of opinion will probably be found in regard to this question, and undoubtedly further investigation work is necessary in order to decide it. A number of different oils have been proposed for the purpose, of which, perhaps, soya-bean is one which has been most prominently discussed. No definite formulas, however, should be recommended until the results of investigations which are now being carried on are in hand. A systematic series of test panels is now being erected in Washington, D.C., on the grounds of the Institute of Industrial Research, which are designed to gather data covering just this point.

The flax crop conditions have been most discouraging during the past two years, and the natural shortage of seed has caused a rise in the price of linseed oil, which has necessitated a rise in the price of paint. The added protection to be secured, however, through the frequent application of paint for outweighs any increased cost which has been caused by the rise in price of the raw commodities entering into the composition of paint.

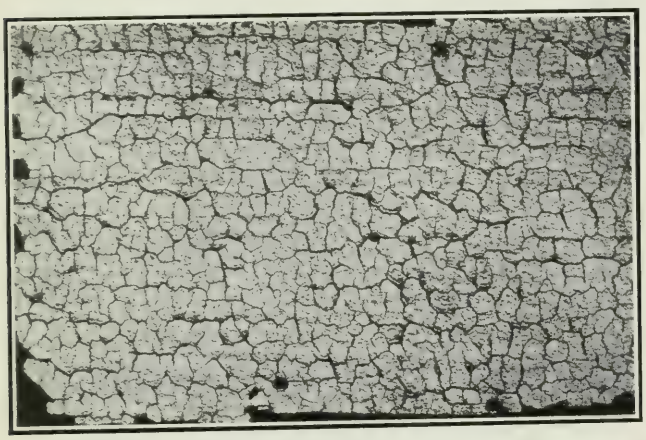
Paints for Interior of Dwellings and Buildings.—The proper decoration of the interior of dwellings and public buildings has become of even greater importance than the protection and decoration of exteriors. There is, moreover, an increased demand for harmonious effects and the production of more sanitary conditions than have prevailed in the past. Up until a few years ago, a great variety of wall papers of more or less pleasing appearance were almost exclusively used for the decoration of walls in the interior of buildings, and their application was commonly considered the most effective means of wall decoration. There seems to be no question, however, that the use of wall paper is steadily decreasing, and that the art of interior decoration is undergoing a transition to the almost universal use of paint.

Modern process demands the maintenance of sanitary conditions for the benefit of the public welfare, and there is no doubt that from the standpoint of sanitation and hygiene, properly painted wall surfaces are far superior to papered walls. There is an abundance of evidence which shows that dust germs may easily be harbored, and thus disease transmitted from wall paper. In the tenement houses which are common to the larger cities, and to a lesser extent in the dwellings found in smaller communities, where tenants are more or less transient, the continued maintenance of sanitary conditions presents a difficult problem. Infectious and epidemic illnesses generally leave behind bacilli of different types, which may find a culture medium in the fibrous and porous surfaces presented by wall paper, backed up as they invariably must be by starch, casein or other organic pastes. Occasionally the restriction of local boards of health provide in such events for proper fumigation, but too often no precautions are taken to destroy the disease germs which are caught in the dust which collects on wall paper. As a rule, both tenant and landlord are obvious to all conditions which cannot be readily seen or detected.

* Dewar, Titzel, et al.

Burning sulphur, one of the most effective means of fumigation, will generally cause bleaching and consequent fading of the delicate colors used in printing the designs upon wall paper. Washing of the paper with antiseptic solutions will destroy its adhesiveness to the plaster and often cause bulging and general destruction.

Hospital Practice.—In hospitals, where it is necessary to maintain sanitary conditions, the walls are invariably painted, and requirements should demand the use of paints which can be washed frequently, so that there will be no possibility of uncleanliness. Inquiry made of a prominent surgeon connected with one of the large metropolitan hospitals substantiated the writer's findings regarding the greater sanitary value of wall paints; and brought forth the information that in hospitals under construction provision had been made for the finishing of walls so that a hard, non-absorbent and washable surface might be obtained. The same authority stated that the common practice, in apartments and tenements, of covering the old wall paper over with a layer of new, each time a tenant moved in, should be condemned, and that from a hygienic standpoint the use of sanitary wall paints should be advocated in all dwellings as well as public buildings.



"Alligatoring."—Type of Decay Exhibited by Improperly Made Paint.

If such conditions are maintained in hospitals, where special attention is paid to sanitation, it would appear that similar precautions should be equally as necessary in public buildings and in dwellings—wherever, in fact, people congregate to live.

Sanitary Wall Paints.—Cold water paints or kalsomines should not be used, as they often contain glue, casein, dextrine and other binders which are easily destroyed. Oil paints which are thinned with turpentine and other volatile spirits are the only real sanitary paints to use. There have recently apeared in trade a number of wall paints composed of non-poisonous pigments ground in paint vehicles having valuable waterproofing and binding properties, and of a nature to produce the flat or semi-flat finish that has become so popular. Such paints produce a sanitary, waterproof surface, which permits of frequent washing. By their use it is possible to secure a more permanent and wider range of tints than can be obtained with wall paper, as they are produced in a myriad of shades, tints and solid colors, from which any desired combination can be selected. On the border or on the body of walls decorated with such paints, attractive stencil designs, which bring out in relief the color combinations, may be applied.

For the decoration of chambers and living rooms, delicate French grays, light buffs, cream tints and ivory whites may be used, while in the library and other rooms richer and more solid colors, such as greens, reds and blues, may be harmoniously combined.

Defects of Wall Paper.—It recently occurred to the writer to investigate the conditions which obtain in many apartment houses in the larger cities. Inspection of a number of such places, in which wall paper had been exclusively used on the walls, showed generally bad conditions; bulging of the surfaces, caused by dampness in the walls, which had loosened up the binder, as well as peeling and dropping of the paper from the ceilings, were frequently observed. In many cases a shabby appearance was shown, accompanied by an odor which suggested decomposition of the paste binder used on the paper. The writer was impressed with the fact that such conditions could easily be avoided by the very simple expedient of using properly manufactured wall paints, which are so easily made dustproof and waterproof.

Samples of wall paper, which had been applied to plastered walls for a year or more, were obtained and examination under the microscope showed a most uncleanly surface. Cultures were made of these samples, and bacilli of different types were developed in the culture medium in a short time.

Experimental Evidence.—That the above conditions could not have existed had proper wall paints been used, seemed doubtless, and suggested a carefully conducted experiment to prove the relative sanitary values of wall paper and wall paints. A large sheet of fibreboard, such as is occasionally used to replace plastered walls, was painted on one side with a high-grade wall paint, three-coat work. A similar sheet was papered on one side with a clean, new wall paper. These test panels were placed where unsanitary conditions, such as dampness, foul odors, and a scarcity of air, were present. After a short period of exposure, the panels were taken to the bacteriological laboratory and a small section of the painted surface, about two inches square, as well as a small section of the papered surface of similar side, were removed and used for making cultures. In each case the surface of the section under test was washed with 100 cubic centimeter of distilled, sterilized water. The washings, which dripped from the surface, were collected in a graduated flask. One cubic centimeter of the washings was used in each case, admixed with bouillon and again with agar-agar. The enormous development of bacteria in the bouillon, treated with the washings from the wall papered surface, was sufficient evidence to convince one of the greater sanitary value of the wall paint, the washings from which gave a culture practically free from bacteria. The colonies of bacteria shown in the petri-dish made of the washings from wall paper further supports these findings. It will be noticed that the tests made from the washings of the wall paint show practical absence of bacteria, and was clear, as was the bouillon-solution test of paint. The washings from the wall paper showed active development of bacteria, both in the bouillon and agar tests.

From the Conservation Standpoint.—It would be of interest to sum up in figures the acreage and cordage of wood that annually is transformed into pulp for the manufacture of wall paper. Unfortunately there are no available statistics on this subject. It is clear, however, that from the standpoint of conservation the use of wall paints should take precedence over the use of wall paper.

Paints for the Prevention of Corrosion of Iron.—The protection of structural steel is a subject that most painters have in the past considered of minor importance, any paint that would properly hide the surface of the metal being accepted without much question. The demand, however, for structural steel for office buildings, factories, steel cars, railroad equipment, etc., has doubled the output of structural

paints, and created a demand for painters having a knowledge of the proper materials to use in the painting of steel, so that its life may be preserved and its strength maintained. Such knowledge is as important to the painter as a knowledge of how to properly select materials for the painting of wood, and how to temper these materials to suit the various conditions met with.

Every one is familiar with the appearance of rust, but few actually understand what causes rust. No attempt will be made here to present even an outline of the many theories advanced to explain the phenomenon of the rusting of iron, for the subject is as diverse as it is interesting. A brief résumé, however, will be given of the now generally accepted theory that explains the subject. This theory is called the electrolytic theory.

"Auto-electrolysis" is the term used to define the peculiar tendency of iron to be transformed from a metal possessing a hard lustrous surface, high tensile strength, and other useful properties, to a crumbling oxide that falls to the ground and again becomes part of the earth from which it was originally taken by man.

This "going back to nature" is more readily accompanied by most of the steel produced to-day than by the old hand-made irons produced many years ago. It seems to be a curious fact that the more quickly a product or an article is fashioned by man, the more quickly it tends to return again to its original oxidized condition. Some manufacturers of steel, however, through an understanding of the causes of rust, have progressed in the manufacture of slow-rusting materials, either by the elimination or by the proper distribution of impurities.

When iron is brought into contact with moisture, currents of electricity flow over the surface of the iron between the points that are relatively pure and points that contain impurities. These currents stimulate the natural tendency of the iron to go into solution, and the solution proceeds with vigor at the positive points. The air which the water contains oxidizes the iron which has gone into solution, and precipitates the brown iron rust with which you are all so familiar. Thus water, which acts as an acid, and air, which acts as an oxidizer, have combined together to accomplish the downfall of the metal. It is obvious that if means could be devised to stop the solution pressure of iron, and make it resistant to the flow of surface electric currents, rust could be prevented. Materials which prevent the rusting of iron have been called by Dr. Cushman, who first advanced these explanations. rust inhibitors, or materials which inhibit rust. The paint maker, realizing the importance of these rust inhibitors, is incorporating them into paints designed for the protection of iron and steel, and the success which paints of this type have met with from a practical standpoint is a justification of what was first called the electrolytic theory which suggested their use. The laws of electrolytic corrosion would be a better way of stating what have become facts, and these laws are a direct result of the early pioneer researches of Dr. Cushman, who was formerly for many years in the Government service, but who is now the director of the Institute of Industrial Research in Washington. By placing small, brightly-polished steel plates into a mush of paint pigment and water, a determination may be made of the pigment's effect upon the metal. Some pigments under such conditions cause rapid corrosion of the steel plates. Such pigments are stimulators of corrosion on account of acid impurities which they contain, or because of their effect in stimulating galvanic currents. Many carbonaceous pigments are of this type. Other pigments have the effect of keeping bright the steel plates and preventing rust. Such pigments are of the inhibitive type, and their action is to check or retard the solution pressure of the iron.

Results obtained in many laboratory tests suggested a practical exposure test, and a series of three hundred large steel plates were exposed by the writer, acting under the American Society for Testing Materials, at Atlantic City, where the action of the salt air is severe on both paint and metal. In these tests separate plates were painted with nearly all the useful paint pigments, ground in a vehicle of raw and boiled linseed oil. Later in the test it was found that many pigments of the carbonaceous type, as well as those which contained acid impurities, were showing bad results. It was also found that pigments of the inhibitive type, such as chromates of lead, zinc, barium, etc., acted in an almost miraculous way, transforming the surface of the metal upon which they were applied into a practically uncorrodible condition.

The excessive chalking which took place on the corroded white lead coatings began to disappear at the end of a year, being washed away by the rains and carried away by the winds, so that there was left upon the surface thin coatings of pigments, insufficient to give good protection. Had this white lead been reinforced with sufficient zinc oxide to prevent chalking, much better results would no doubt have been obtained.

The deep cracking of the zinc oxide indicated that such a pigment required a large quantity of oil in order to satisfy its brittle nature and prevent such effects. White paints containing zinc oxide and zinc oxide products were in excellent condition, and they confirm preliminary tests which showed zinc oxide to be one of the most valuable pigments for protecting iron.

Although sublimed white and blue leads chalked very heavily, the chalked pigment seemed to be tenacious, and adhered to the plate, presenting a good surface with absence of rust. Both these pigments gave very good protection to steel. When admixed in the right proportion with certain other pigments, they give still better results.

Lithopone was early destroyed, as is usual with the pigment when used alone on exterior surfaces. It became rough and discolored, presenting a very blotchy appearance. Red lead and orange mineral both afforded excellent protection to the plates upon which they were applied. They became covered, however, after exposure with a white coating of carbonate of lead, which was due to the action of the carbonic acid of the atmosphere on the red lead, which is an oxide of lead, and susceptible to chemical action.

The iron oxide gave fair service indeed. In one case, however, there were several eruptions, indicating slight corrosion beneath the surface of the paint. One iron oxide which did wonderfully well was the black oxide of iron which not only possesses great tinting value, but up to the present time has had a high protective value. The graphite was very deeply pitted at certain spots, indicating that galvanic currents had been set up, causing stimulating effects. Barytes and blanc fixe, when used alone, gave very poor service, showing scaling, chalking disintegration, and rust soon after the test was started. Barytes, combined with some other pigments, however, presented a very good surface. Under the paint film of gypsum rust soon appeared, and although the film itself remained fairly intact, rusting progressed throughout the test, indicating that gypsum films were very poor excluders of moisture. Coal-tar paints failed in the test, and this was due, no doubt, to the strong action of the sun, which early destroys such products. China clay and asbestine gave excellent service for eighteen months. After that time, however, indications of corrosion were shown, and the apparent breakdown of the film was predicted. These pigments, however, combined with other pigments, have given excellent service.

American vermilion, zinc chromate, zinc-and-barium chromate, chrome green, Prussian blue, and zinc-and-lead chromate gave most wonderful service, presenting an appearance within two years that was almost identical with their appearance at the start of the test. These pigments with red lead, zinc oxide, litharge, sublimed leads, combinations of lead and zinc, willow charcoal, neutral oxide of iron and the inert pigments, will allow the design of paints of nearly any color. From their admixture properly adjusted with a good paint vehicle, and tested by the expert, will come the final solution of the problem that has bothered painters and engineers for so many years. The vehicle for such paints should be made of linseed oil with or without the addition of treated linoleates, tungates, and fossil gums, until such a time as a modern research has found a vehicle more suitable.

THE HEYWOOD SEWAGE PURIFICATION AND REFUSE DESTRUCTOR WORKS.*

By R. J. McKenn, Manager.

The refuse destructor works were opened on June 15th, 1903, and have since been regularly working. The plant consists of two front-feed units of the Meldrum patent "Simplex" regenerative type, hand fed, and having an effective grate area of 50 square feet, and works in conjunction with a Lancashire boiler, 20 ft. long by 7 ft. diameter, with a total heating surface of 570 square feet, working at a pressure of 150 lb. per square inch. The "Simplex" grate consists in having the furnace chamber common to the number of grates. This arrangement of continuous grate ensures the maintenance of an evenly high temperature, and allows of one section being cleaned and charged while the other is in an incandescent state, and as the gases commingle in the furnace, and again in the combustion chamber, complete immunity from dust or smell from gases leaving the chimney is ensured. The temperature in the combustion chamber varies from 1,700 deg. Fahr. to 2,000 deg. Fahr. The gases of combustion pass from the furnace into the combustion chamber, through the boiler and its settings in the usual manner, thence through the regenerator to the chimney flue. The regenerator, or air heater, consists of a number of cast iron tubes, through which the gases of combustion pass to the main flue. The air for combustion drawn by the steam jet blowers, which produces the forced draught, circulates round these tubes, and becomes heated in its passage to a temperature of from 250 deg. Fahr. to 350 deg. Fahr., this temperature varying with the quantity and quality of the refuse, as also the size of the boiler. The refuse for consumption in the destructors is obtained from dry ashpits and a good number of privy middens. That from the latter often contains 65 per cent. of moisture, and is of low calorific value. The average amount of water evaporated per pound of refuse is 0.62 lb. The engine-room contains a non-condensing engine, 8 in. diameter cylinder by 14 in. stroke, running at 160 revolutions per minute. This engine drives a 7 ft. diameter mortar mill, and a compound air compressor 8 in. and 6 in. diameter cylinders by 12 in. stroke, with a working pressure of 100 lb. per square inch, also a small inverted direct-coupled engine and dynamo, which gives 20 ampères at 200 volts. The current generated is used for lighting the works.

Sewage Purification Works.—It is now approaching eighteen years since the construction of the Heywood Sewage Works was commenced under the present engineer, Mr. Jas. Diggle, Assoc. M. Inst. C.E., F.G.S., of the firm of Messrs. Jas. Diggle and Son, of Westminster and Heywood. The actual commencement of the scheme was made on August 13th, 1894, but after the work of construction had proceeded some time a most unfortunate discovery was made. It was found that a worked-out coal mine existed practically over the whole site. This caused the committee and engineer considerable anxiety; and instead of the works being built with the usual foundations, it became necessary to excavate to a great depth and fill in with concrete. The foundations vary in depth from a few feet to 56 feet. This, together with pumping the water out of the old mine, added enormously to the cost of the works.

Heywood has a population of 27,000, and the rateable value is £121,700. The sewage treated at the works consists of, besides domestic sewage, manufacturing waste. It may be stated that the council adopt the policy of allowing manufacturers to run their waste into the sewers after treatment. The manufacturing waste consists of liquids from tanneries, flannel scouring, dye works, breweries, and paper stainers. The dry-weather flow of sewage is 850,000 gallons, and the major portion gravitates to the works, and enters by an egg-shaped culvert 4 ft. 6 in. on the major by 3 ft. on the minor axis. Passing through the primary screen, the screening bars of which are 2 in. mesh, the sewage is conveyed to the works by means of a cost iron pipe, 36 in. diameter, 300 yards long, and discharges from an inverted bell-mouth pipe. Part of the sewage is diverted on to a high breast water wheel 14 ft. diameter by 3 ft. wide. The energy generated by the water wheel is utilized for driving the secondary screens, which are of ⅜ in. mesh. A further portion of the sewage is diverted into an Adams lift, where energy is generated free of cost (with the exception of attention for cleaning), for lifting a maximum of 108,000 gallons of sewage per twenty-four hours from Hooley Bridge, which is a low-lying district. This low-level sewage enters the forcing cylinders through retentive valves, which prevent its return when the air pressure is applied. When a forcing cylinder has filled, the supply of high-level sewage used for energy is automatically turned on through the syphonic feed into the flush tanks placed overhead in the air chamber. Each flush tank when full automatically discharges its contents through the deep trap syphon and fall pipe into the air cylinder immediately below, to which it is connected. The air contained in each of these air cylinders is thus expelled as required, and by means of the air pipes is brought to exert its pressure on the low-level sewage contained in the forcing cylinder to which it is connected. The low-level sewage is thus forced automatically to the required level. The air cylinder is now full of high-level sewage, but is at once emptied by the simple syphon attached, and, so after being utilized for work, passes by gravitation to the disposal works. Thus the low-level sewage is raised automatically entirely without cost for energy, and with a minimum of oversight.

After the sewage has performed these functions it is again united, and passes alongside the overflow weir, which is set up to pass the sewage, in excess of three times and up to six times the dry-weather flow, on to the storm filters, which have an area of 6,200 square yards. The sewage from one to three times the dry-weather flow is then charged with alumino-ferric, and passes through the baffle channels and on to the precipitation tanks. There are six of these, with a total capacity of 710,000 gallons, and they are worked on the continuous system.

* Paper read before the Institution of Municipal Engineers at Heywood, Manchester, England.

When the works were originally constructed, contact filters were laid down. There were twelve in number, with a total area of 1,325 square yards. These gave excellent results, but they were not sufficient to deal with the whole volume of sewage; consequently it was necessary to construct additional beds. There are twelve beds, constructed on the percolating system, each 60 ft. diameter by 8 ft. deep, having a total area of 3,720 square yards. The sewage is distributed on to the beds by means of the "Simplex" distributing apparatus. This apparatus can be set to feed the beds in rotation for any desired period of time. When No. 1 bed has had a ten minutes' supply the distributor automatically diverts the flow to No. 2 bed for ten minutes, and so on throughout the series. Should the flow of sewage increase through rain or any other cause, one bed is not sufficient to deal with the flow, and the distributor automatically brings additional beds into action in ratio to the flow, and as the flow decreases the beds go out of action in ratio to the flow. The cycle of changing is going on continuously. Provision is also made which enables any bed in the series to be put out of action by simply placing a disc on the distributor, for no matter how well a sewage works may be managed there are times when the beds become sick and require a rest.

The bacteria beds are constructed on a concrete base, cone-shaped—that is, the centre of the beds is higher than the outer circumference. This allows the effluent to run to the effluent channels, which are constructed round the outside of the beds. The filtering media is laid on floors constructed with Ames-Crosta's floor tiles, which give a free access of air under the beds and allows a free passage for the humus matter to escape. The outside walls are constructed of pigeon-hole brickwork, 14 in. thick for 4 ft. high and 9 in. thick for the remaining 4 ft., and eight buttresses are constructed to each bed. As the effluent discharges from the beds it is collected by two main carriers, which convey it to the humus tanks. These tanks, two in number, are each 130 ft. long by 24 ft. wide, and vary in depth from 18 in. at the inlet to 2 ft. 6 in. at the outlet sills. These tanks are cleaned out every week. A Shone's ejector of 50 gallons capacity is fixed for raising the humus sludge from the humus tanks up to the precipitating tanks. This ejector is worked by compressed air, and works against a head of 24.62 ft., exclusive of pipe friction.

The sludge from the precipitation tanks gravitates to the sludge well, which is situate under the engine-room. A cast iron box is fixed in this well, into which the sludge falls, and when a charge is required compressed air is turned on and the contents of the box ejected up and into the sludge mixer. There are three sludge presses, each fitted with twenty-eight plates. The press liquor runs from the presses into a steel boiler-shaped receiver, and when the rams have discharged the sludge into the presses, the exhaust air is conveyed to the steel receiver; the whole of the press liquor being thus raised to the precipitation tanks. The energy required for driving the agitating gear in the mixer, also the hauling gear for bringing the pressed cake to the top road, is obtained from a 6 in. diameter cylinder engine by 12 in. stroke, which is driven by compressed air.

Automatic samples are fixed on the crude sewage inlet to the Adams lift tanks, the effluent from the precipitation tanks and the final effluent. This is an advantage, and obviates the necessity of workmen taking samples every hour. The appliances are simple and work continuously, thus ensuing an average sample being obtained extending over the twenty-four hours.

OZONE PLANT OF THE CENTRAL LONDON RAILWAY.

The management of the above underground railway has recently attempted to improve the condition of the air in their runways by the addition of an ozone plant manufactured by the Ozonair Company. As an experiment, the railway officials installed a trial outfit in the Bank Street station about two years ago and the results obtained justified the extension of the system to other stations along the line.

The supply of ozone is dependent upon the well-known principle of the silent electrical discharge on the oxygen of the air. At each station the equipment includes a rotary converter, a transformer and a motor-driven Sirocco fan; accessory to these are air washers and filtering screens. This apparatus is fixed at surface level and usually in the booking hall whence the upper air is drawn into the particular local system. Reference to Fig. 1 will explain the details of the arrangements employed. In each plant air is drawn from outside through a fine copper mesh filter screen, over the surface of which a thin film of water continually flows. This washes the incoming air, removing dirt and smuts, and deleterious gases.

The air is drawn into a Sirocco ventilating fan driven by a motor of 7 h.p., where it meets a comparatively strong ozone mixture delivered from an adjacent ozone generator, and is discharged in its ozonized and purified condition through trunking to the station platforms down below.

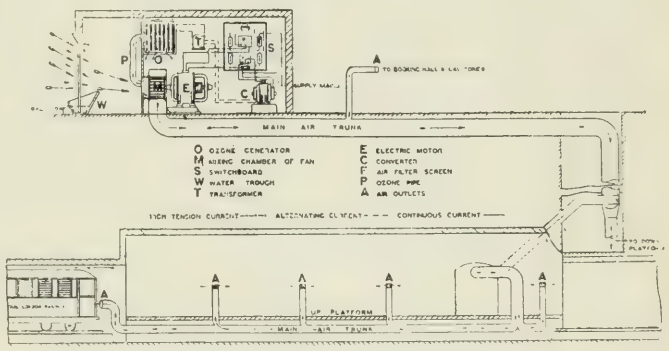


Fig. 1.—General Diagram of Ozonizer Plant at Tube Stations, Showing Details of Equipment and Delivery Ducts.

The ozone apparatus consists of 10 mica and gauze generating units, the gauze sheets being supplied with current at 5,000-6,000 volts pressure from the secondary of a small transformer, the primary of which is connected to the 380-volt a.c. side of a small rotary converter, running on a 550-volt d.c. circuit. A suitable switchboard is provided for controlling the fan motor and converter, and the whole apparatus is exceedingly compact and controllable as to the amount of air delivered and strength of the added ozone mixture, according to temperature or barometric requirements; moreover, the working is practically automatic.

In each station a small proportion of the clean treated air is supplied to the ticket office, lavatories, etc., on the surface; the remainder passes down a main trunk to a distributing duct under each platform, rising branches delivering air at a height of about 7 feet above platform level.

The large ducts under the platforms are continued about 40 feet along the tunnels in the direction in which the trains leave, with a view to the trains themselves assisting in the circulation of the treated air through the tunnels. About a third of the total air delivered is distributed over the platforms, the remainder being delivered into the tunnels.

A DOSING APPARATUS FOR WATER SUPPLIES.

An apparatus for introducing a chemical reagent into water flowing through a pipe under pressure is described in a recent issue of The Engineer (March 29, 1912).

In this device, shown diagrammatically in the figure herewith, the pressures in the mouth and throat of the Venturi tube at A are communicated to the two vertical tanks B and C respectively, so that the height of liquid in these two tanks varies with the Venturi pressures. In these tanks are suspended the hollow cast-iron cylinders G and F, hung from hooks in the end of the balance beam with fulcrum at E. These cylinders are so proportioned that their specific gravity is somewhat greater than unity, so that they are submerged in the liquid in the tank.

With no water flowing through the main the pressure at the mouth and throat of the Venturi tube is the same and consequently the liquid in the two tanks B and C stands at the same height, say at H_1 in the figure. Under these conditions the cylinders G and F will hang at the same height. The lengths of the rods connecting the cylinders to the balance beam are so proportioned that with the cylinders at the same

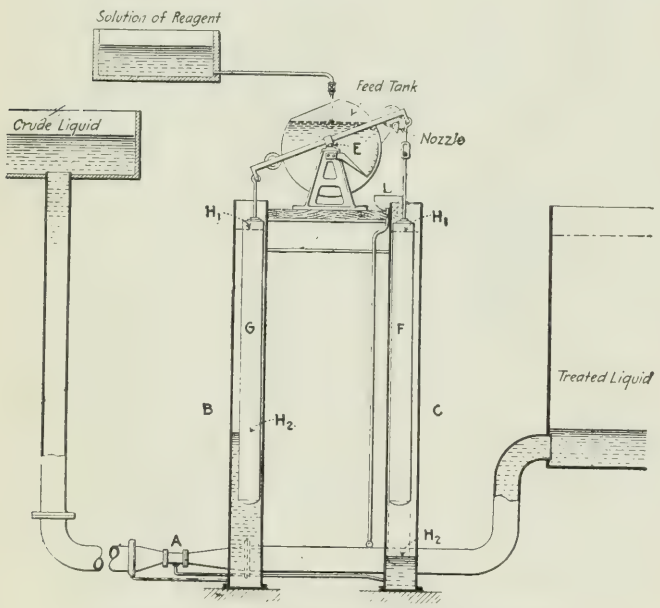

Diagram of the Tiltometer Dosing Apparatus.

height the feed tank, which it attached to the balance beam, will be in such a position that the level of the solution in the feed tank will be just below the discharge nozzle. The level of the solution in the feed tank is kept constant by a float valve. The position of the tank can be adjusted by means of the turnbuckle in the rod at the right end of the beam in the figure.

When the water is started flowing through the main, the water level in both tanks will fall, say to the levels of H_2 in the figure, with the level in the left-hand tank, connected to the mouth of the Venturi tube, higher than that in the right-hand tank, connected to the throat of the tube. As a result the equilibrium of the cylinders and balance beam will be disturbed and the right-hand cylinder F will descend sufficiently to equalize the immersion of the two cylinders. This motion of the cylinders causes the balance beam and consequently the feed tank to be tipped down at the right, so that some of the solution in the tank flows out through the nozzle into the cup L and then through the feed pipe into the main.

The amount by which the feed tank is tipped and consequently the head producing the flow of solution through the feed nozzle is proportional to the movement of the cylinders G and F and therefore to the difference in head at the mouth and throat of the Venturi tube. Hence the quantity of solution added is at all times proportional approximately to the amount of water passing through the main. The orifice of the feed nozzle can be adjusted to give the desired number of grains of solution per gallon of water treated.

It is claimed by the manufacturer, George Kent, Ltd., of High Holborn, W.C., London, England, that the variation in the proportion of solution added does not exceed 1⅔% from the mean under the most extreme conditions of working. In support of this claim, the following results are given of tests made upon one of these devices:

Water.	Solution. gals. per hr.	Per cent.
640	19.8	3.09
1720	52.2	3.04
1820	57.2	3.14
2390	73.7	3.08

The device has been patented jointly by the Hon. R. C. Parsons and Mr. Walter G. Kent. It is manufactured under the trade name of "tiltometer."

HEAVY-OIL ENGINES.

The first of a series of four lectures under the Howard Bequest, on the subject of "Heavy-Oil Engines," was delivered by Captain H. R. Sankey before the Royal Society of Arts on the 29th ult. Captain Sankey began by pointing out that some twenty years ago there was only one form of oil-engine of which the Hornsby-Akroyd and Priestman could be taken as types. These engines required external heat at starting for the evaporation of their fuel, and worked on paraffin. In 1890 Daimler invented the petrol-engine which worked with petrol having a specific gravity of about 0.68, and which required no external heat for the evaporation of its fuel, while in 1897 Diesel introduced his engine, which worked with heavy oil, and required no external heat, as the fuel was mechanically pulverized instead of being evaporated.

Oil-engines at the present time were, Captain Sankey said usually considered as divisibe into two casses: the light-oil engines, which used fuel capable of forming explosive mixtures at ordinary temperatures, and having a specific gravity ranging from 0.68 to 0.72, and heavy-oil engines, which used fuel requiring high temperature or mechanical pulverization, for the formation of explosive mixtures, and which had a specific gravity ranging from 0.8 to 0.9. He proposed in his lectures to confine himself entirely to the heavy-oil class. In the Diesel engine the compression took place entirely on a charge of air, into which the fuel was afterwards injected, so that there was no danger of pre-ignition, and compression pressures up to from 450 to 500 pounds per square inch could be used. It was in its high compression that the great efficiency of the Diesel engine lay. In the semi-Diesel type of engine, in which, after compression of air, the fuel was injected into a hot bulb, there was no danger of pre-ignition, but compressions up to about 200 pounds per square inch were usually found sufficient to ensure ignition.

Captain Sankey, after pointing out that the Diesel engine was the most important of the heavy-oil class, and stating that he proposed to devote the greater part of his four lectures to it, then gave a brief history of its development, beginning with Dr. Diesel's first example of 1897. Incidentally, and in connection with his historical summary,

Captain Sankey suggested that the relative backwardness of this country in the development of the Diesel engine was due to the cheapness of our coal. He thought, however, that great progress was likely to take place in the future, particularly in connection with marine work.

Captain Sankey then dealt in a comparatively elementary way with some theoretical aspects of the Diesel engine. He drew a comparison between water-wheels, or water-turbines, and heat engines, pointing out that while the possible work which might be obtained from the former depended only on the height of the head of water, the possible work which might be obtained from the latter did not depend merely on the head of heat available—i.e., on the temperature—since the question of the specific heat of the working substance had to be taken into account. Captain Sankey illustrated this point by means of a heat-chart, and compared the efficiency of the Diesel cycle with the Carnot cycle. He pointed out that the Carnot cycle involved both admission at constant temperature and exhaust at constant temperature, and stated that Dr. Diesel's original idea had been to construct an engine working on the Carnot cycle and using pulverized coal as a fuel. In the Diesel engine admission took place at constant pressure and exhaust at constant volume, as compared with the gas-engine and petrol-engine, in which admission took place at constant volume. This difference gave the Diesel engine an advantage, since there was a greater difference between the upper portions of the actual and theoretical diagrams in the two cases. The economy of the Diesel engine was also largely accounted for by the high compressions, up to from 450 pounds to 500 pounds per square inch, which could be used. These figures compared with from 130 pounds to 150 pounds per square inch for gas-engines, and 70 pounds to 80 pounds per square inch for petrol-engines. In the latter cases the figure had to be kept low for fear of pre-ignition.

Captain Sankey then referred to the temperature reached in the cylinder of a Diesel engine. This was usually stated to be about 1,000 deg. Fahr., but he thought the figure too low. He did not know that the temperature had ever been directly measured, but the formula for the temperature of compression of air showed that the temperature should be about 1,500 deg. Fahr. No doubt it would be less than this in practice, owing to conduction loss, but he suggested that it was usually nearer 1,200 deg. or 1,300 deg. than 1,000 deg. He thought the temperature of 1,000 deg., which was so frequently given, might be explained on the assumption that, in calculating the matter, the lower temperature of the air had been taken as that of the outer atmosphere, but, arguing from gas-engine practice, it was likely that this lower temperature was nearer that of boiling water than of the atmosphere. Captain Sankey then traced through the various operations of the four-stroke cycle and two-stroke cycle of the Diesel engine. He pointed out that with a two-stroke cycle gas-engine there was danger that some of the new working charge might be blown out of the exhaust by the scavenging air, but that in a Diesel engine this could not happen, so that the Diesel might be looked upon as essentially a two-stroke engine. It was usual practice in such engines to admit scavenging air to about 80 per cent. greater amount than the volume of the cylinder. The four-cycle Diesel was more economical than the two-cycle, owing to the slight loss at the toe of the diagram with the latter consequent on the entry of the scavenging air.

INTERMITTENCY IN ELECTRIC TRACTION.

In a paper read before the Society of Engineers of England on "Intermittency: its Effect in Limiting Electric Traction for City and Suburban Passenger Transport," Mr. Wm. Yorath Lewis remarked that intermittency was a characteristic common to all systems of passenger transport in general use, and, while it might not be an objectionable feature in the case of a trunk line railway with long distance trains, its effect upon urban and suburban passenger transport was extremely detrimental. In city, urban, and suburban service the inherent nature of the traffic was that of a continuously flowing stream, which varied considerably in volume at more or less definite periods of each day, maximum density occurring at morning and evening during what were known as the "rush" hours. Usually the flow was along well-defined and regular channels between certain localities, but periodically the traffic stream was diverted, and was often augmented in volume, according to special circumstances. The means for dealing with this human stream should, consequently, partake so far as was practicable, of a continuous as distinguished from an intermittent nature.

Results of Intermittency.—The result of damming a human stream moving at the rate of three miles an hour—if the volume was four abreast six feet apart, and if the period of check was only one minute—consisted in the accumulation of a crowd of 176 people, meaning discomfort and a serious time loss of more than one minute, because of the time required to enable this detachment to board the conveyance, pending the arrival of which it had accumulated. Obviously, if instead of interrupting this human stream, accommodation could be provided with a capacity of, say, about three seats per second passing through the station at a speed sufficiently slow to enable the passengers to step on or off the cars, all delay and congestion would be eliminated. There would be neither the need of a station platform, nor of trains long and large enough to accommodate the assemblage. The present method of dealing with the situation consisted in providing a distinctly intermittent service of trains of limited capacity, run at sufficiently short intervals to ensure the passing of, say, 10,560 seats per hour through the stations. This involved, with 50-seat cars and, say, six-car trains, 35 trains per hour. The Metropolitan District Railway now ran over a section of its lines during the rush hours 40 trains an hour in each direction. Assuming that these trains were composed of six 50-seat cars, their capacity was 12,000 seats per hour. The length of the train was 300 feet, necessitating platforms about 400 feet long. The corresponding time interval between the trains was 90 seconds. The schedule speed was about 15 to 16 m.p.h., and the stations averaged half a mile apart, whilst the average stop at each station was about 20 seconds. As the trains were made up of six 50-foot cars, the aggregate length of train passing hourly through a station amounted to 12,000 feet, or 2.28 miles.

Defects of Present Methods.—The intermittent character of the train-system service was the factor which limited the schedule speed, and consequently the capacity of the line. The limitation of the speed necessitated a larger amount of rolling stock than would be requisite for the same capacity, were it possible to maintain higher schedule speeds. It would manifestly be impracticable and commercially impossible to negotiate such an intensity of service as that of the present underground railways of London, if the stations were to be located at an average distance of only one-quarter mile apart; although, from the viewpoint of traffic and public convenience, stations at these shorter intervals were highly desirable in the case of city and urban routes. Here again the intermittent characteristic proved

to be the bugbear of the electric train system, but still further detrimental effects might be indicated. The maintenance of an intense service (say, 12,000 seats an hour in each direction) involved the problem of starting a heavy mass in the nature of a long train, accelerating this mass to a high speed and then retarding it to rest forty times an hour. With the electric train system this was rendered possible only by providing equipment of a very costly and complicated nature, which involved much skilled attention and a considerable element of human labor for its operation and control. Furthermore, a system involving the transportation of passengers in crowds instead of in streams required not only long, but also very bulky trains, which could be accommodated only in relatively spacious tunnels and at long station platforms. The stresses due to the severity of the service and the weight of the electric apparatus and accessories necessarily carried on the train were so great that the aggregate weight of the rolling stock rarely averaged less than 1,000 pounds per seat, and for more severe services it was much higher. Consequently the permanent way had to be of a substantial nature, and such locations must, notwithstanding the expense, be acquired for the railway, as to eliminate all possibility that neighboring property should be affected by the vibration resulting from the periodic passing of heavy rolling loads.

Conclusion.—The author then discussed acceleration, brake losses, energy consumption, and fixed charges, and finally submitted that in respect of the electric train system, the fundamental cause of its inherent limitations, its excessively high initial and operating costs, and its consequent inability to meet adequately the requirements of the dense traffic usual in all large cities, was its characteristic "intermittency." He urged that in view of the future, which undoubtedly demanded better and cheaper transit facilities in the interest of the community, recourse must be made to the continuous plan because, as he had endeavored to show in a paper read before the Royal Society of Arts on "Continuous Service Passenger Transportation in Relation to the London Traffic Problems," the difficulties which attended the present cumbersome method did not exist in that method, and consequently the prospects of superior achievements were relatively much brighter. He mentioned that it is proposed to put down a full-size railway on the Adkins-Lewis system of about a quarter of a mile in length on the Aldwych island site in order to enable the public to ascertain whether they could mount and dismount the cars when moving at a constant speed of two or three miles an hour. It is considered that, although the system has been demonstrated successfully by the Ipswich experimental plant, the next step in its development must be of the nature of a public trial.

HYDRO-ELECTRIC DEVELOPMENT AT PRINCE ALBERT.

Some time ago we noted that the city of Prince Albert intended to instal a municipal hydro-electric plant at Lacolle Falls on the North Saskatchewan River. The work is now under construction. The completed plant will cost in the neighborhood of a million dollars and will be completed in less than two years. The municipality of Prince Albert are financing the undertaking and Messrs. C. H. and P. H. Mitchell, Toronto, are the engineers. The development includes headworks, dam, navigation lock, power canal, intake works and power house. The contract for the headworks has been let to the Ambursen Hydraulic Construction Company, of Montreal, for $578,000. This contract includes the dam, a navigation lock 40 x 150 feet long and 6 feet deep, and the intake works. The power canal leads from the headworks to the power house, half a mile below the dam, and the excavation will be mainly in boulder clay. With the water available during minimum flow 12,000 horsepower can be produced, while the head obtained will be 30 feet. The turbines will be of the vertical type and six units will be eventually installed. Two will be placed immediately, of 2,000 k.v.a. capacity. The voltage used on the transmission line to Prince Albert will be 35,000. This will be stepped down to 2,300 volts in the local receiving station.

GRILLAGE FOR I-BEAMS.

The conventional base for columns of buildings is a cast-iron (or, in recent years, cast-steel) shoe, of sufficient size of bottom to suit the permissible loading of the stone or concrete foundation. E. W. Stern, consulting engineer, of New York City, has developed a base of the I-beam grillage type, as an improvement on cast bases, which is described in a recent issue of Engineering News, from which this description is taken. A typical design of his form of base is shown by sketch, Fig. 1, herewith. In a letter Mr. Stern gives the following comparisons:

"1. In comparison with cast-steel bases, the grillage base is both cheaper and more reliable. In my own experience, I have had cast-steel bases develop cracks after having been erected, although they had been carefully annealed and inspected before leaving the shop. These had to be replaced after several stories of steelwork had been erected, which entailed very considerable expense.

"2. In comparison with cast-iron, it is cheaper and very much more reliable. In an experience extending over many

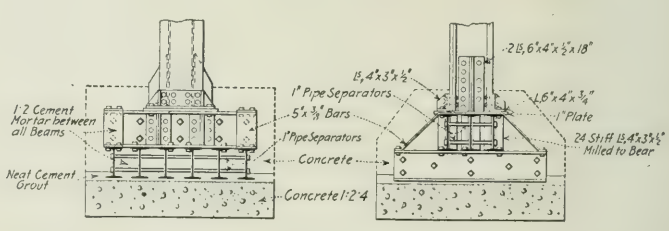

Fig. 1.—Typical I-Beam Base for a Building Column.

years in the use of cast-iron bases, I have known far too many to have developed cracks after they had been erected in the building, often entailing large expense for replacing them. For this reason I have not been using cast-iron bases for about 10 years.

"3. The grillage form of base is easier to set properly being much more readily grouted.

"4. Stresses can be readily calculated (which cannot be said of the usual design of cast base). The conventional method of analysis for shear, crippling and bending is accurate enough or all practical purposes."

The design shown has been used on loads up to 16,000 tons, and by slight modifications it may be used for much larger loads.

Shallow beams with heavy webs are preferred, avoiding the necessity of reinforcing the webs. However, Mr. Stern always uses stiffeners ground to fit, in the upper tier of beams, whether or not the calculations show them to be required.

In building these grillage bases, the beams are bolted up complete in the shop, and each tier of beams is bolted together, ready for erection in one piece. Pipe separators should be used plentifully, and in the top layer they should be spaced not over 6 in. vertically and in. horizontally. After setting, the base is, of course, grouted, all spaces between beams being filled with 1:2 Portland cement mortar.

The Canadian Engineer

ESTABLISHED 1893.

ISSUED WEEKLY in the interests of the CIVIL, MECHANICAL, STRUCTURAL, ELECTRICAL, MARINE AND MINING ENGINEER, THE SURVEYOR, THE MANUFACTURER, AND THE CONTRACTOR.

BRITISH MANUFACTURERS.

A party of British business men and manufacturers arrive on June 6th at Quebec on a visit of inspection of the Dominion. The party will make an exhaustive tour from coast to coast, visiting all the chief cities and industrial centres. The tour has been organized by the Financial News of London, which of late years has devoted marked attention to Canadian affairs, and under whose auspices the trip will be carried out, with the hearty co-operation and support of the Dominion Government. In speaking of the proposed trip, the Financial News says: "The British Dominion of Canada is clearly intended by Nature to be an industrial, as well as an agricultural, land of the first magnitude. She possesses the raw material of modern industry in an almost boundless degree. Her reserves of timber (the last great stands in the world), with proper care, are practically inexhaustible; iron, copper, and all the metals required in manufactures are present in great abundance; her coal fields are vast, and already are being profitably worked at many points of her wide territory. Natural gas, oil, and other fuels also abound. To crown all, her waterpowers are capable of indefinite expansion at moderate cost—already in her eastern provinces the horse-power developed from water runs well into seven figures. Judged from her infinite capacities in this respect alone, Canada is a potential manufacturing country of the first rank."

This trip should be the means of developing the already cordial spirit existing between the Mother Country and her leading colony. It will give these men, who are the leaders in the financial and manufacturing world, an opportunity for studying at first hand the conditions that exist in the Dominion for the establishment of branch factories, the openings for capital in industrial undertakings, and the possibilities of extending the market for British-made goods. Their reception throughout the country will be most friendly. It is difficult to foresee the far-reaching results which will flow from an intimate inspection of this nature, but it will be certain to develop the trade relations between the two countries by opening up new avenues of commerce and broadening the existing ones.

ROADS.

The question of good roads is at last receiving the attention it deserves. Our neighbors to the south of us are much farther advanced along this line than we are. Necessity has forced them to take action, and as a result, in the last few years a great deal of road construction has been done. In New York State practically all the towns and cities are united by first-class highways, and in nearly all cases these roads are built for the particular service and traffic for which they are used. In the last two years a great impetus has been given to good road construction in Canada. We believe, however, that too little attention is being paid to the choice of roadway for the particular traffic expected for it. This is a very important requisite; in fact, we would say the most important consideration at the present time in the design of a highway. Maintenance is dependent to a large extent on the kind of roadway and

the class of traffic, and, unless these two things are co-related, the good roads question is liable to receive a serious setback. When the York County Highway Commission of Ontario first outlined their programme, it was expected that the better class of roads, or that class which may be termed permanent, would not be necessary. However, after consideration, the Commission has decided that on many of the main arteries of traffic leading into the city of Toronto it would be advisable to put down a more permanent road than can be secured with water-bound macadam. There is little question that these main thoroughfares will carry an immense amount of traffic over what they are at present handling, and this will mean, if the poorer type of road is used, that it will quickly disintegrate and break down under the heavy travel. The Commission has approached the city and the Provincial Government to secure funds in order that this new programme may be carried out. It is to be sincerely hoped that funds will be placed at their disposal for this work, for nothing but failure can result in the use of a type of road which is not adapted for the traffic conditions.

FLAMELESS GAS HEAT.

The supremacy of gas fuel for industrial and domestic heating purposes is amongst the revolutionary developments anticipated in consequence of recent research at Leeds University. Means have been discovered by which gases can be made to "burn" without a flame and yield temperatures that have been hitherto unattained by gaseous combustion. Details of the phenomenon of flameless heat which underlies this discovery were given before the Cavendish Society at Leeds University recently by Professor W. Bone, D.Sc., F.R.S., the professor-elect of fuel at the Imperial College of Science and Technology. These results, Professor Bone stated, were the outcome of many years' scientific research upon "the accelerating influence of hot solids upon gaseous combustion," conducted by himself and Mr. C. D. McCourt, in continuation of the investigations by many prominent scientists during the early part of last century.

The distinguishing feature of the new process is that an explosive mixture of gas and air, when caused to burn without a flame in contact with a granular incandescent solid, resulted in a large proportion of the potential energy of the gas being converted into radiant form. The advantages: (1) That combustion is greatly accelerated by the incandescent surface, and, if so desired, may be concentrated just where the heat is required; (2) the combustion is perfect, with a minimum excess of air; (3) the attainment of very high temperatures is possible without the aid of elaborate "regenerative" devices, and (4) owing to the large amount of radiant energy developed, transmission of heat from the seat of combustion to the object to be heated is very rapid.

The process has been industrially applied in two principal forms. In the first, or diaphragm method, a scientifically proportioned mixture of gas and air is passed under slight pressure through a porous screen of fireproof material. Once the surface of the diaphragm attains incandescence, the gases burned without flame on the surface of the screen. The actual combustion is confined within a very thin layer below the surface, and a wall of fire, but without flame, can be steadily maintained as long as required. Combustion is not only perfect, but is independent of the nature of the external atmosphere. This method is specially adapted to such operations as grilling and roasting, and to the evaporation of liquids from above. In the second method, a prearranged mixture of gas (or vaporized oil) is injected at high speed through a jet into a bed of granular fireproof material which surround the body to be heated. So great are the temperatures obtained by this method that the greatest difficulty is experienced in obtaining material to withstand the heat. Not only has temperatures exceeding 360° Fahr. been secured with coal gas, put the gas consumption requisite to maintain any given temperature is only about half that required in similar furnaces fired by flame contact.

If the claims for this method are fulfilled in its practical commercial application, a vast improvement in the heat efficiency of gas fuel will result. Its use under industrial conditions will be viewed with interest. The value of technical research and investigation is becoming more and more pronounced each year. A university at the present time which does not strive to aid human knowledge and endeavor by the carrying on of research for the purpose of improving industrial and manufacturing processes is not serving the best reason for its existence. There is room for vast improvement in our Canadian universities in this respect.

EDITORIAL COMMENT.

We are glad to note that the Council of the city of Toronto are considering a proposal to limit the height of buildings there to ten stories. We have commented in *The Canadian Engineer* many times on the evils resulting from the erection of high buildings. There is little justification for the existence of a building over ten stories high, and there are many reasons against their use.

* * * *

The Commission of Conservation are doing good work throughout the Dominion along many lines. It is to be hoped, however, that the Government will soon appreciate the necessity for adequate measures with regard to the question of regulation of stream flow and the provision of storage reservoirs. In the near future this question will have to be taken up; in fact, it is necessary now. Little work can be done on it, however, in a practical way until investigations covering the rainfall, run-off, and stream flow have been made, and all the available records compiled and brought up to date. Some of this work has been done by the different Provincial authorities, but the work should logically come under, and will be best done, by a central body, such as the Commission of Conservation.

STREET SPRINKLING IN ST. PAUL, MINN.*

By C. L. Annan, M. Am. Soc. C.E.

For years the citizens of St. Paul put up with unsatisfactory street sprinkling. In the earlier years the work was done by contract, the cost being roughly assessed, at considerable expense, against the property supposed to be benefited. Then, as a substitute, an annual appropriation was included, for a few years, in the general tax levy to meet the cost of springling by day labor. The result was intolerable. Finally, at the general election in May, 1908, a sprinkling amendment was submitted to the people, and in 1909 the commissioner of public works took charge of street sprinkling under this amendment.

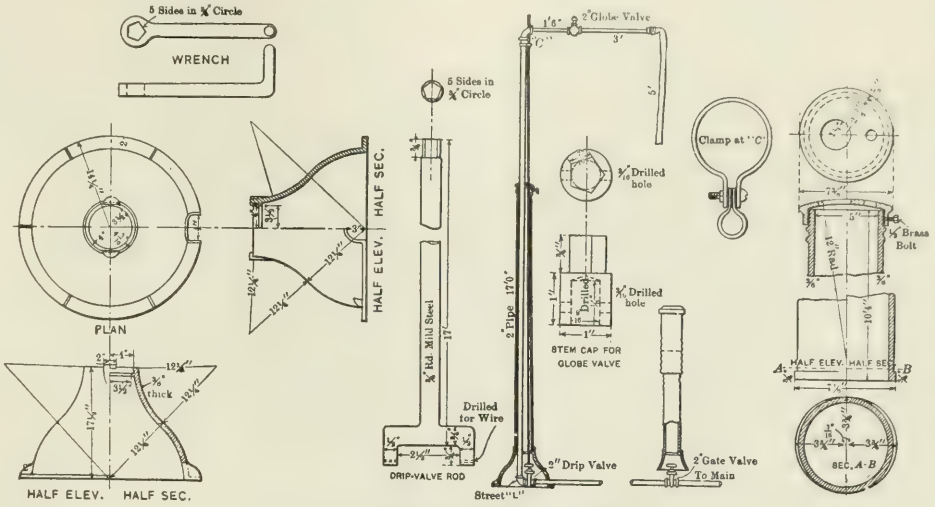

Fig. 1.—Stand-Pipe and Gate-Box.

The system inaugurated at that time has been fairly perfected, and it has been demonstrated that systematic attention to details has brought results at least commensurate with the cost.

Fig. 2.

The amendment provided for an appropriation of $[illegible], for the first year and an additional $40,000 for the second year. By that time the system should be smoothly running under the revolving fund fed by the assessment of the property benefited.

The third season under the new law opened with about 230 miles of streets to be sprinkled. New routes were added from time to time and a few were discontinued, resulting in a total gain for the season of about 9 miles. There is generally strong opposition to the discontinuance of a route once started.

From two to eight trips, depending on the nature of the street surface and the amount of traffic, are made each day. There are nine sprinkling districts, each under the supervision of an inspector at $75; a chief inspector or overseer at $110 is also employed. The ten inspectors report daily. The chief inspector advises and assists local inspectors and makes special examinations. The inspectors' reports are tabulated daily; all complaints are investigated, and the written reports are filed for reference. The foreman of stand-pipe construction and repair crews receives daily instructions, and the yardmaster returns a daily statement of sprinkler distribution and repairs. Careful itineraries on each team route are taken from time to time, and, in short, the head of the department is intimately informed of all details concerning equipment and operation.

Form 152 5-21-1911. 3M. MEMORANDUM NOS. 145

Fig. 3.

In assessing the cost of the work, the abutting frontage, number of trips per day, and length of time sprinkled, are taken into consideration. For the season of 1911, 43 assessment rates thus resulted, ranging from less than 1 cent to 11½ cents per front foot of abutting property. The cost of water is not included in the assessment, the city charter so providing.

Water sprinkling of macadam was suspended early in the season by oil spraying. It was estimated that about 1/5 gallon per square yard of a 20 per cent. liquid asphalt might be applied three times during the season at a cost not to exceed that of water sprinkling for the same period. The latter part of the season being usually wet, comparatively few streets required the three coats of oil.

* Paper to be presented Sept. 18th, 1912, to the American Society of Civil Engineers, and printed in the Proceedings of the Society for May.

The sprinkling wagons are city property; 40 new and 31 second-hand sprinklers, varying in capacity from 600 to 750 gallons, were purchased in 1903. Twelve 750-gallon tanks were added in 1909, and as many more in 1910. These 95 sprinklers allowed a 10 per cent. reserve. All were in good repair after a thorough overhauling during the winter.

Teams were used for 7 days in the week at $100 per month, rain or shine, under an agreement with the Teamsters' Union. Previous to April 1st, teamsters were allowed $4 per day for actual time.

Inspectorships, formerly political sinecures, were transformed to realities. Consistent daily reports, investigations of complaints, route itineraries, and first-hand information as to condition of sprinklers and stand-pipes, require a certain amount of attention.

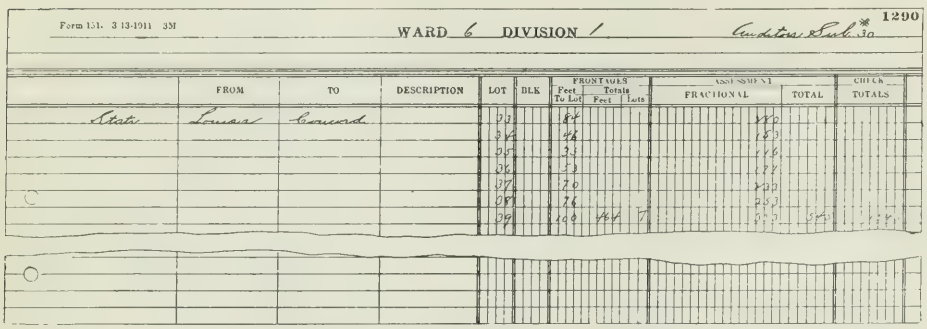

Fig. 4.

Five men at $2 and a team at $3 keep the stand-pipes in repair under the supervision of a foreman, who also attends to the maintenance of the public drinking fountains. This force also moved 16 stand-pipes from one point to another and erected 17 new ones in 1911. A stand-pipe, installed, (Fig. 1) costs about $60. The top valves are removed in October to prevent damage by freezing, and are replaced in April, an underground valve being used in March and November. There are 463 stand-pipes now in service.

The stand-pipe is quite generally regarded as a nuisance, and much opposition is met in locating it. It is not so much its unsightliness as the frequent presence near it of the heavy sprinkler, the standing horses, and the general sloppiness that makes is objectionable.

For washing ice, mixing cement, and other purposes, the stand-pipe is a great convenience to any outsider with a pipe-wrench. The water department and the police had long overlooked this kind of larceny, but a few arrests by special officers of the sprinkling department, and a few trials and convictions, now and again, somewhat abated this nuisance of mud and damaging misuse.

The method of assessing is as follows: A clerk, at $60, enters the daily report (Form 150, Fig. 2) on Form 152, Fig. 3, and indexes complaints and special orders to inspectors by number on the same form. Complaints are taken in duplicate on a general department form, the duplicate being held against the inspector until he turns in his report.

Form 152 is arranged in a check file divided into districts by tab cards of a distinctive color. The districts are subdivided into routes by cards of another color, one compartment in each district being reserved for "dead" trip slips. The current trip slips will not average more than ten to a route, so they are readily accessible, though the aggregate may be considerably more than 1,000.

Trip and route numbers may be changed on a trip slip (Form 152) but a change of limits necessitates new slips and cross-references and the consigning of the obsolete slip to the "dead" division until required for assessment purposes. All assessment forms are handled on the loose-leaf system.

Two men, at $80, are employed from March 15th to August 1st in making a transcript from the county auditor's records on Form 151 (Fig. 4) and preparing assessment sheets (Form 166, Fig. 5). The force is then doubled to make the assessment, post, and check it, the work to be completed early in October.

The assessment rate, A, per front foot of property abutting on any particular section of sprinkled street is derived as follows:

D = trips per day on the particular route,

M = sprinkling period, in months and tenths for the same route,

C = D × M (nearest integer),

F = total frontage on same route,

P = C × F,

S = sum of products, P, for all routes,

T = estimated total cost of sprinkling all routes. (From the five months actual record a close estimate can be made for T).

$$R = \frac{T}{S},$$

Then $A = C \times R$.

An idea of the method of procedure and of the relation of volumes may be obtained by particular reference to the assessment of 1911. The daily record, on Form 152, was summarized on Form 154 (Fig. 6), embracing 1,439 sheets in twelve groups, one for each ward, each group arranged alphabetically by street names and bound with flat-head fasteners. The coefficient, C, having been determined for each slip, the 1,439 slips were rearranged in 43 groups,

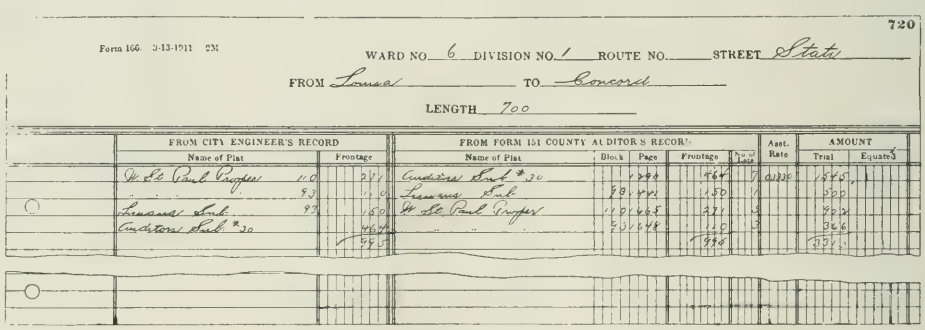

Fig. 5.

corresponding to the variations of C. A five-column table was then prepared with a line for each value of C, thus:—

C	F	P	F × R	C × R
1.....	34,006	34,006	62.91	0.00185
2.....	69,252	138,504	256.63	0.00370
		and so on, to		
62.....	62,965	3,903,830	7,222.09	0.11470
	2,567,815	50,529,857	93,480.24	

The total of Column P is S. The total of Column F × R is T. R is obviously the first item in Column C × R. R being constant, there are as many values of A as there are of C and F × R, for each group is checked by the total.

The entries on Form 154 are now completed, and the slips are rearranged in ward groups. In the meantime, Form 166 has been prepared to correspond with each sheet of Form 154, of which it is an extension applied to the property to be assessed. Form 166 is arranged alphabetically. When complete, the sheets are paged consecutively from the first sheet of Ward 1 to the last sheet of Ward 12.

Fig. 6.

The assessment is finally made on Form 151, there being as many sheets of this form as there are block numbers involved on the various plates and subdivisions named on Form 166.

For instance, on page 720 of Form 166 there are four blocks of property containing lots to be assessed. There will consequently be four corresponding sheets of Form 151. These sheets are arranged alphabetically by plot names in ward groups, and they are also paged consecutively.

Page 1290 (Fig. 4) is a specimen sheet whereon the seven lots in the Auditor's Sub. No. 30, noted on the first line of page 720, are entered in detail. The 1911 assessment contained 3,472 sheets of Form 151.

The cost of making the assessment of 1910 was a little more than 2 per cent., but City Railway complications raised this ratio to more than 3 per cent. in 1911.

Early in May, 1911, the Supreme Court of the State decreed that the St. Paul City Railway Company must at once comply with the ordinance of October, 1909, requiring this company to sprinkle its tracks. As an immediate alternative, the company agreed with the commissioner of public works to pay the sprinkling department for doing the work. The cost of sprinkling streets traversed by the City Railway was to be prorated as to time and space from the totals of the general assessment for the same streets. Form 190 (Fig. 7) was provided for this record.

Fig. 7.

As soon as arrangements could be made, the City Railway Company sprinkled many miles of its track space with road oil.

The occasional itinerary which has been referred to has proved to be a practicable and an excellent feature. It was called for at irregular intervals, and the returns assisted in determining the efficiency of both teamsters and inspectors. Each teamster and inspector is furnished with a specific route sheet, and the care taken to equalize routes is generally appreciated and tends to the good of the service. The routes as traveled are reported on Form 173 (Fig. 8). They are platted on light blue prints. A summary is made of the number of tanks of water used and of the feet of effective and idle travel in a half day. The 45 sq. miles of sprinkling area are covered by 34 tracings (8½ by 13½ in.) on a scale of 600 ft. to 1 in., and from these tracings the blue prints referred to are made as required.

Among the many owners of the 50,000 lots, more or less, assessed, there are many complainants who desire to know the particulars, and, for the benefit of this class, a special form has been prepared. Occasionally, a correction is necessary; there were only twenty on the first assessment made under this system.

Fig. 8.

The assessment for each ward is cross-checked and balanced to a cent. A concluding word may be said as to the daily reports, Form 150 (Fig. 2). Each section of street has its trip number. The small figures under the trip numbers show the number of trips actually made for the day. Under Route 4 it will be noted that Trip No. 31 lacks the sub-number. The explanation immediately follows. To write "31" is equivalent to writing "Indiana Avenue, from South Robert Street to Hyde Street." On May 18th Trip No. 31 was divided. A portion of it (No. 84) being transferred from Route 4 to Route 7.

Each inspector keeps a consecutive list of last numbers in his district and can thus assign a new number when necessary.

MOVEMENT TO IMPROVE INDUSTRIAL CONDITIONS IN EASTERN CANADA.

Colonel Vince, who is a member of the public utilities commission of New Brunswick, has stated that natural gas will revolutionize industrial conditions in the province, if it is found in sufficient quantities to supply St. John and other places as it does Moncton at the present time. Borings are being continued in the oil region in Albert county and will probably also be made in King's county.

THE ALLOYS OF ALUMINUM AND ZINC.

At a recent meeting of the Institution of Mechanical Engineers, Dr. Walter Rosenhein and Mr. S. L. Archbutt, of the National Physical Laboratory, presented the Tenth Report to the Alloys Research Committee of the Institution on the "Alloys of Aluminum and Zinc."

The principal results obtained in the investigations described in the present (Tenth) Report to the Alloys Research Committee are briefly summarized as follows:—

(1) The Constitution of the Alloys.—This is only briefly dealt with in the report, since a full account of the metallographic study of the aluminum-zinc system has already been published elsewhere. The new equilibrium diagram arrived at by the authors is reproduced, showing the occurence of reactions and the formation of a definite compound (Al_2Zn_3) whose existance had not previously been established. From the equilibrium diagram it appears that all the alloys containing more than 40 per cent. of zinc undergo transformation at a temperature of 256 deg. C. (493 deg. Fahr.). As regards the alloys at and near the aluminum end of the series, the new equilibrium diagram establishes their "solidus curve" or temperature of complete solidification, and also exhibits certain minor transformations which, although shown not to be due to a change in the pure aluminum-zinc system, always occur in commercial alloys at temperatures near their melting-point. The alloys containing less than 40 per cent. of zinc are shown to be simple homogeneous solid solutions, although it is possible that the inversion of 256 deg. C. also occurs at this end of the series. When cast in chill moulds, the microstructure of these alloys exhibits the sharply "cored" structure usually found in rapidly cooled solid solutions having a long range of solidifications. In sand-castings this coring is less sharply defined and the whole microstructure is on a larger scale. The "cores" are entirely removed by prolonged annealing at such a temperature as 400 deg. C. (752 deg. F.), but they are removed rapidly and completely by the rolling process. Photomicrographs of the hot-rolled alloys, especially after annealing, containing up to 25 per cent. of zinc, exhibit the typical polyhedral structure of a perfectly homogeneous solid solution, although the scale of the crystals varies considerably according to the exact mode of treatment which the material has undergone.

The Study of the Cast Alloys.—Tensile tests on sand and chill-castings of a series of alloys covering the entire range of the binary system are given, both in tabular and graphic form. The tensile strength of sand-castings shows a steady increase up to a concentration of 50 per cent. of zinc, when an ultimate stress of 18.7 tons per square inch is reached; there is then a slight fall of strength with further increase of zinc-content, followed by a rise to a second maximum near 75 per cent. of zinc, a concentration which corresponds approximately to the composition of the compound Al_2Zn_3. The highest ultimate stress reached is 18.9 tons per sq. in. The table and curve representing the results of tests on chill-castings is some what different in type, three maxima being observed, namely, the first at 30 per cent. of zinc with an ultimate stress of 17.9 tons per sq. in., the second at 50 per cent. with 21.6 tons per sq. in., and the third at 75 per cent. with 20.1 tons per sq. in. The yield-points for both sand and chill-castings are recorded as observed, but the observations were found to be somewhat uncertain in the case of the cast alloys.

In discussing the results of tensile tests on the present series of alloys the authors have used the term "Specific Tenacity," to denote a quantity which is proportional to the tensile strength and inversely to the specific gravity; this has been calculated by dividing the ultimate stress of a given alloy in tons per sq. in. by the weight of a cubic inch in pounds. The quotient is the breaking load in tons of a bar of the material whose cross-section is such as to make the weight of the bar 1 lb. per in. length. From the point of view of tensile strength alone this figure may be regarded as representing the value of any structural material, and allows of comparisons on a correct basis between materials of widely different specific gravity, such as these light alloys and steel. In the cast alloys the specific tenacity is found to reach its maximum for both sand and chill-castings in an alloy containing approximately 26 per cent. of zinc. The value attained is just over 150, as compared with a maximum value of 126 reached by the light alloys described in the Ninth Report. In the light alloys of aluminum with copper alone the specific tenacity of casting does not exceed a value of 99.

Compression tests on a number of chill and sand-castings of the alloys, including some of higher zinc-content, have been made. These tests show that in general terms the behavior of the castings under compression is approximately proportional to their behavior under tension. The highest yield-stress under compression was obtained with alloy No. 55 in the chill cast condition, giving a stress of 22.96 tons per sq. in. It is curious to find, however, that the chill-castings are decidedly inferior to the sand-castings until a zinc-content of about 50 per cent. is passed.

The question of the possible "ageing," or even gradual spontaneous disintegration of the aluminum-zinc alloys has also been studied in connection with the sand-cast material, tensile tests of some of the alloys being repeated on specimens which had been kept for over fifteen months, but no signs of any change were observed.

Study of the Wrought Alloys.—Billet of the alloys containing up to and including 26 per cent. of zinc were cast at the Laboratory and were rolled and drawn to various sizes, including wire and sheet, at the Milton Works of the British Aluminum Company. Hot-rolling was found possible with all these alloys, but not with an alloy containing 30 per cent of zinc.

Tensile tests on a representative series of alloys lying between the limits of composition just named were made on material in the form of (1) bars hot-rolled to 1¼ in. diameter, (2) bars hot-rolled to ⅞ in. diameter, (3) bars hot-rolled to ½ in. diameter, (4) bars cold-drawn to 13/16 in. diameter, (5) bars drawn with annealing to 13/16 in. diameter, (6) cold-drawn wire 0.1285 in. diameter, and (7) sheet of 0.14 and 0.07 in. thickness. In addition, the material in the form of ⅞ in. bars hot-rolled, 13/16 in. cold-drawn, hot-rolled ½ in., and wire, as well as sheet of both thicknesses, was also tested after annealing for one hour at 400 deg. C. The tensile tests on all the hot-worked material gave very uniform and consistent results which can generally be represented by reasonably smooth curves when the data are plotted against zinc-content. The yield-points in these tests, as contrasted with those on castings, are well-defined and as regular as the results for ultimate stress.

In the form of 1¼ in. hot-rolled bars, the alloy No. 26 attains a tensile strength of 27 tons per sq. in., with a yield point of 25 tons per sq. in. and an elongation of 16.5 per cent. on 2 in. Both the tensile tests on 1¼ and on ⅞ in. hot-rolled bars give curves of ultimate stress plotted against zinc-content which are very similar to one another, but it is a striking feature of these alloys that the curve for the smaller section lies above that for the larger only up to a zinc-content of about 12 per cent.; above that concentration the 1¼ in. bars give higher ultimate stresses than the ⅞ in. bars. The results of tests on still smaller sizes of material, even including the hard-drawn wire, show corresponding results, although the crossing-point of the respective curves

differs from one size of material to another. The general conclusion is demonstrated that the beneficial effect of "work" on these alloys diminishes steadily with increasing zinc-content, until the 25 and 26 per cent. alloys are reached, in which we find that the highest ultimate stress is always given by the 1¼ in. hot-rolled bars. These alloys, richer in zinc, therefore, present the unusual property that cold-drawing a bar from 1¼ in. to 13/16 in. diameter, although it raises both yield-point and elastic limit and lowers elongation and reduction of area, actually reduces the ultimate stress.

The condition (excluding wire) of highest tensile strength, together with the yield-stress and elongation corresponding to that condition, are given for a series of typical alloys in Table 1.

Table 1.

No. of the Alloy (also per cent. Zn)	Condition for Highest Ultimate Stress	Ultimate Stress	Yield-Point	Elongation on 2 inches
		Tons per sq. in.	Tons per sq. in.	Per cent.
5.....	⅞-in. hot-rolled bar	8.94	7.4	26
9.....	⅞-in. hot-rolled bar	11.17	6.98	38*
11.....	⅞-in. hot-rolled bar	13.78	9.42	35*
13.....	13/16-in. cold-drawn bar	14 73	12.80	19.5
17.....	1¼-in. hot-rolled bar	19.85	13.20	22
20.....	1¼-in. hot-rolled bar	22.64	17.3	20.5
26.....	1¼-in. hot-rolled bar	27.09	25.00	16.5

* On 1 inch.

The tensile tests on annealed material were undertaken principally to ascertain whether the peculiar effects of "work" mentioned above persisted after annealing, and the results are discussed with reference to the resulting microstructures. It was found that the "hot-rolled" materials exhibited a considerable amount of deformation in their constituent crystals, and that this deformation was entirely removed by annealing, although the scale of the resulting structure differed widely according to the treatment which each specimen had received. In general terms it was found that the tensile strength of the annealed materials was not strictly proportional to crystal size, but that the more severely worked material always exhibited better results after annealing than less severely treated metal. The highest ultimate stress in annealed material of the present series of alloys was obtained from alloys No. 20 in the form of annealed cold-drawn wire, the value being 21.1 tons per sq. in., but it must be noted that the higher alloys of the series (Nos. 25 and 26) were not included in all the tests on annealed material.

The tests on wire and sheet gave results which have already been referred to in connection with the effect of work and of annealing. Sheets were rolled from alloys Nos. 15 and 20; the former rolled well, but the latter cracked somewhat at the edges. The tensile tests show considerable variations as regards yield-points between longitudinal and transverse tests, although these are obliterated to a considerable extent after annealing. The yield-stresses, however, gave very erratic results, and this is probably to be ascribed to slight surface cracking of the metal. In the cold-rolled condition, alloys No. 20, in the form of sheet 0.07 in. thick, gives an ultimate stress of 23 tons per sq. in., but there is little or no elongation in this condition. After annealing the ultimate stress falls to 18 tons per sq. in., but the elongation reaches 10 per cent. on a longitudinal and 6.25 per cent. on a transverse test.

As regards the tests on the alloys in the form of wire, it was found possible to obtain even alloys Nos. 25 and 26 in this form, but the results given by these were disappointing, since they were lower than the tests obtained with 1¼ in. hot-rolled bars. In the annealed condition, however, these wires give results which appear to be promising; thus No. 19 gives an ultimate stress of 21 tons per sq. in. with 17.7 per cent. of elongation. It is interesting to note that the tests on annealed wire exhibit a well-defined maximum in tensile strength at or near a concentration of 20 per cent. of zinc.

Tensile tests at high temperatures were made on a series of the alloys in order to ascertain the effect of zinc-content on the rate of loss of strength of these alloys with increasing temperature. Most of the alloys were tested up to 200 deg. C. (392 deg. Fahr.), but in two cases considerably higher temperatures were employed (up to 595 deg. C.). In every case it is found that there is a rapid fall in the yield-stress and ultimate stress with rising temperature, even 50 deg. C. producing a marked effect. The rate of loss of strength varies according to the composition of the alloy; thus at 100 deg. C. the alloys containing up to 13 per cent. of zinc have lost about 36 per cent. of their tensile strength at the ordinary temperature; the alloys containing from 15 to 17 per cent. show a loss of 44 to 52 per cent., but this figure again diminishes to 26 per cent. for alloy No. 26. These relative rates of loss are confirmed at higher temperatures. At still higher temperatures the strength of the alloys becomes exceedingly small, but they exhibit a remarkable degree of ductility as measured by elongation and reduction of area; the latter in some cases is so great that the fracture is drawn down to a sharp point, while the elongation in one instance reached 133 per cent. Forging tests, however, show that this extreme ductility exists only under "static" loads, and that the alloys which draw out to the fine points in the testing machine are broken into small fragments if struck sharply with a hammer at the same temperature.

The elastic properties of the alloys have been determined both for the hot-rolled and cold-drawn materials. They exhibit a satisfactory elastic behavior and show well-defined elastic limits, which increase regularly with the zinc-content and consistently with the ordinary yield-point determinations. The elastic moduli of all the alloys are almost identical, lying near the value 9×10^6, a low value which may prove a disadvantage for certain possible uses of the alloys.

Torsion tests have been carried out on specimens cut from the alloys in the form of 1¼ in. hot-rolled bars, comparison of the results with those of tensile tests shows that the torsional strength, although it increases considerably with increase of zinc-content, yet does not increase as rapidly as the tensile strength. The ratio of the maximum stresses under the two forms of test falls from 1.10 for alloy No. 9 to 0.76 for alloy No. 25.

The hardness numbers of the alloys, again in the form of 1¼ in. hot-rolled bar, have been determined by the Brinell method under loads of 1,000 and 3,000 kg. respectively and by the Shore scleroscope. The proportionality between the hardness numbers and tensile strength is found in these alloys to be only of a general kind, the shapes of the respective curves being notably different.

Compression tests have also been made on the wrought alloys. The results are in strict conformity with those of tensile tests, although the compression yield-stresses are always slightly higher than those found in tension.

Dynamic tests have been carried out on the alloys both with the machines designed for that purpose at the National Physical Laboratory under the direction of Dr. T. E. Stanton, and also by the kindness of Professor J. O. Arnold at the University of Sheffield. The tests made at Teddington include direct alternations of stress, repeated-bending impact and single-blow impact.

The tests in alternations of direct stress give a series of results for the safe range of alternating stresses for the

alloys, and this curve lies considerably below that of the static elastic limits. These ranges, although low when compared with the ordinary tensile test results, yet indicate a very decided advance on other light alloys which have been described in the Ninth Report. The best of those alloys (of aluminum with copper and manganese) showed a safe range of 9.4 tons per sq. in., while the best of the present series has a range of 12.0 tons per sq. in.

Alternate-bending impact tests made with a weight of tup of 4.71 lbs. and heights of fall of 1.0 in. and 0.71 in. respectively. Both sets of tests give curves of very similar shape which show that after 15 per cent. of zinc the resistance to this test is strictly proportional to the zinc-content of the alloy. Of the present alloys, No. 9 shows a resistance practically equal to that found in the best of the light alloys described in the Ninth Report (about 600 blows with a fall of 0.71 in.), while the best alloy of the present series (No. 25) required 3,400 blows for fracture. This power of resisting repeated impact is particularly noteworthy in view of the fact that the aluminum-zinc alloys are frequently spoken of as being weak under shock.

Single-blow impact tests, made on the Izod machine, show that the work absorbed by fracture reaches a maximum for a zinc-content lying between 15 and 20 per cent. This is in accordance with the fact that such tests are affected by both tensile strength and ductility, so that the increased tensile strength of the alloys containing more than 20 per cent. of zinc is more than outweighed by their lower ductility so far as this test is concerned. As compared with the light alloys previously studied, the present series are decidedly superior, although the difference is not so marked as under some of the other tests.

Under Professor Arnold's alternate-bending test, the alloys gave remarkably uniform results, but the curve of number of alternations endured falls rapidly with increase of zinc. Professor Arnold remarks that the resistance of these alloys to his test varies from ⅛ to ¼ that of the heat-treated best mild structural steel. It is interesting to note, in comparing the results of the three last-mentioned forms of dynamic test, that the curves representing their results are closely related to the curves of ultimate stress and elongation or reduction of area as shown by tensile tests. Thus the repeated-bending impact tests give a curve which is closely proportional to that of ultimate stresses, while the results of Professor Arnold's tests are proportionate to the ductilities of the alloys as shown by elongation or reduction of area. The single-blow impact tests, on the other hand, appear to be proportional to the sum of these two properties.

In view of the results of all the mechanical tests the authors arrive at the conclusion that an alloy containing about 20 per cent of zinc probably represents the best combination of properties obtainable in the simple binary aluminum-zinc series.

Corrosion tests on specimens of these alloys exposed to the sea have been carried out for a period of over 500 days, and the results show that the rate of loss of weight under such exposure increases with increase of zinc-content. The actual rate of loss, however, is not as great as might have been anticipated, varying, when allowance for the difference of density is made, from 1½ times that of Naval brass to 1½ times that of Muntz metal. The authors, however, regard their corrosion tests as purely preliminary, since the alloys were used in the cast state, while subsequent study suggests that annealed material would show considerably less corrosion. The method of measuring corrosion by loss of weight is also regarded as inadequate for the study of these alloys, and further corrosion tests are being undertaken.

A general feature of some importance in connection with all the alloys described in the present report, and particularly with those containing from 10 to 30 per cent. of zinc, is the great facility with which they can be worked by machine tools of all descriptions, in most cases without the use of any lubricant. Turnings of exceptional length and strength have been obtained from several of these alloys. The machined surfaces retain their brightness in the air of the laboratory for many months without protection of any kind.

Attention is directed to the Appendix, in which the authors give a preliminary account of the properties of a tenary alloy of aluminum with zinc and copper (alloy No. 25/3) containing approximately 25 per cent. of zinc and 3 per cent. of copper. This alloy, which can be rolled hot, although special care is required in dealing with it, gives remarkable results under mechanical tests. An ultimate stress of 34 tons per sq. in. has been attained with this material, while its resistance to repeated-bending impact is over 4,500 blows, as compared with 3,400 of the best of the binary alloys. Tabulated results of tests made on this alloy are given, but a fuller discussion of its properties is postponed until a systematic study of these ternary alloys has been completed.

ELECTRICALLY OPERATED VALVES.

By H. M. Cassman.

Valves of 24 in. diameter and larger are usually operated other than by hand, for the reason that generally such valves must be closed in a very short time, which is impossible by hand operation, and also because such valves are frequently located in out-of-the-way places, and are more conveniently controlled from some operating point more or less remote from the valves.

As large valves usually control very important service connections it is essential that the electrical equipment of these valves be dependable. To guard against failures the valves should be inspected and tried out regularly, particularly where they are likely to remain in one position for long periods.

The power required to open a valve is a maximum when starting the valve from its seat. After the gate has been opened, say, one-fourth, comparatively little torque is required to complete the operation. The proportion of starting to running torque varies with the construction of the valve, the amount of corrosion and the condition of the valve seat. When closing hydraulic valves under pressure, the starting and running torques are comparatively small until the valve is about three-quarters closed. From that point on, the pressure on the gate increases approximately as a square of the decrease in the opening; consequently the torque at closing in such cases increases rapidly, but does not reach the value of the starting torque required to open the valve under the same pressure conditions.

To overcome the sticking of the valve when it is to be opened, the drive is sometimes provided with a lost-motion device, so as to give a hammer blow when starting the valve from its seat. With alternating-current motors such lost motion also allows the motor to develop a high speed, and, therefore, a greater torque before starting the valve from its seat.

Unless some provision is made for limiting the torque of the motor or controlling the circuit when closing the valve, it is possible to jam and injure the mechanism of the valve, making further operation difficult. A slip gear

* From a paper delivered at the Pittsburg meeting of the American Institute of Electrical Engineers, April 25th to 27th.

cannot be used for this purpose, as the slipping torque in opening will be practically the same as when closing, unless the gear be designed to act in the closing direction only.

Where compactness is a consideration the motor is rigidly attached direct to or on an extension of the valve casing. The motor and drive should be so arranged that there will be ample room for hand operation. An inclosed motor is preferred on account of exposure to dampness, water and flooding, enclosing being permissible without affecting the size of the motor, owing to the intermittent service. Terminals and wiring also must be protected against water and any mechanical injury which might result while repairs are being made to the valve.

A valve should not be overpowered by a motor, for the reason that there is considerable risk of damaging the valve, and should not be underpowered, because it increases the chance of failure when the conditions are extraordinary. The correct size of motor for the valve will very with the duty and the general conditions under which the valve operates.

Where there is any choice of system, the direct current is preferred in order to secure the advantages of a series-wound motor, giving a high starting torque and increased speed under light load. The commutator and brushes, however, are apt to give trouble in damp or wet locations. The alternating-current motor best adapted to valve operation is the squirrel-cage type because of its simplicity. The motor should be designed with a high resistance rotor to increase the starting torque.

For equivalent performance—that is the same assurance against failure of the motor to operate the valves—the alternating-current motor should be from 20 to 40 per cent. larger than the direct-current motor. In such applications motor efficiency does not enter, but operating efficiency does, and, therefore, it is economy to put on motors of greater capacity than would be actually required under ordinary conditions.

For remote control the ideal arrangement is one which permits of automatically starting and stopping the motor by simply throwing a switch or controller, and one that makes it impossibe to start the valve in the wrong direction and wreck some part of the valve or mechanism.

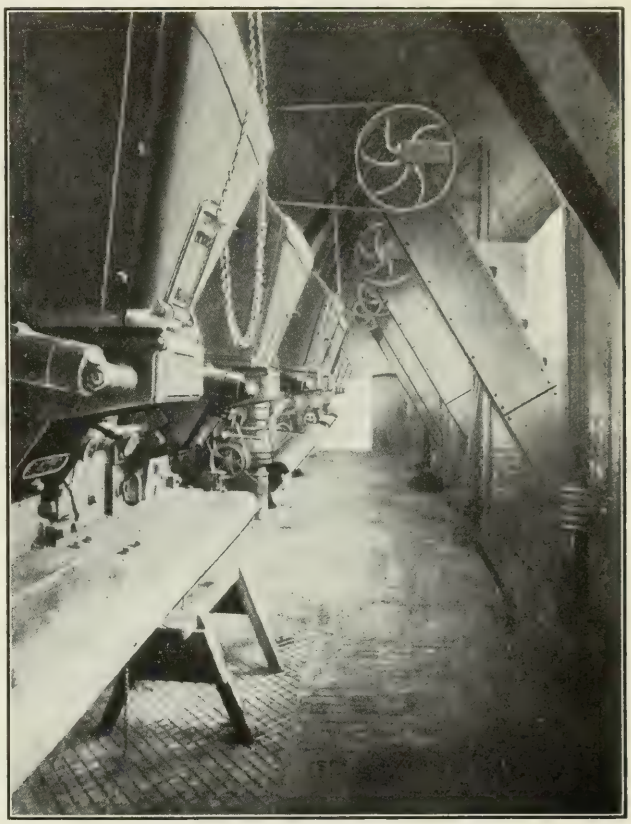
Where valves require direct-current motors larger than can be thrown directly across the line without resistance, such resistance should be designed to give the maximum torque required to open the valve and be retained permanently in circuit. As the motor speeds up, due to a decrease in load, a step of sufficient resistance should be inserted in series with the motor to prevent excessive speed at light load, to slow down the motor as the torque increases near the closing point, and to limit the torque finally should the valve seat itself before the motor is disconnected from the circuit. There are various schemes for obtaining this result with a two-point reversing drum controller or with a pilot switch control in combination with shunt and series-wound contactors. In either case, limit switches should be provided at each end of the travel.

For alternating-current motors the same general scheme can be used, as this type of motor will not increase in speed appreciably with change in load, but the resistance in the stator circuit will also have the effect of limiting the torque in closing the valve.

The limit switches can be designed to handle the motor current instead of the contactor exciting current. For small valves the limit switch is sometimes omitted and the motor allowed to increase its torque to the point of operating an overload circuit-breaker. Such an arrangement, however, is not fool-proof, in that it allows the operator to start the gate in the same direction at the end of its travel.

THE ALEXANDRA (NEWPORT AND SOUTH WALES) DOCKS AND RAILWAY.

The progress of Newport is a record of almost marvellous development and expansion. Newport is to-day the largest and most important town in the county of Monmouth, and it is a great deal more than that. It is one of the busiest and best equipped seaports in Europe, and is, moreover, located in one of the most "growing" districts in the world. Newport is, of course, an important industrial centre, with large ironworks and other manufacturing undertakings. The principal industry is the mining and exporting of coal. In a recently issued booklet on the port and its products, the writer graphically describes the uses to which the famous South Wales and Monmouthshire coal is put. He says: "The battleships of the world are bunkered with coal which has sailed down the Bristol Channel from Newport and her sister ports. This coal has



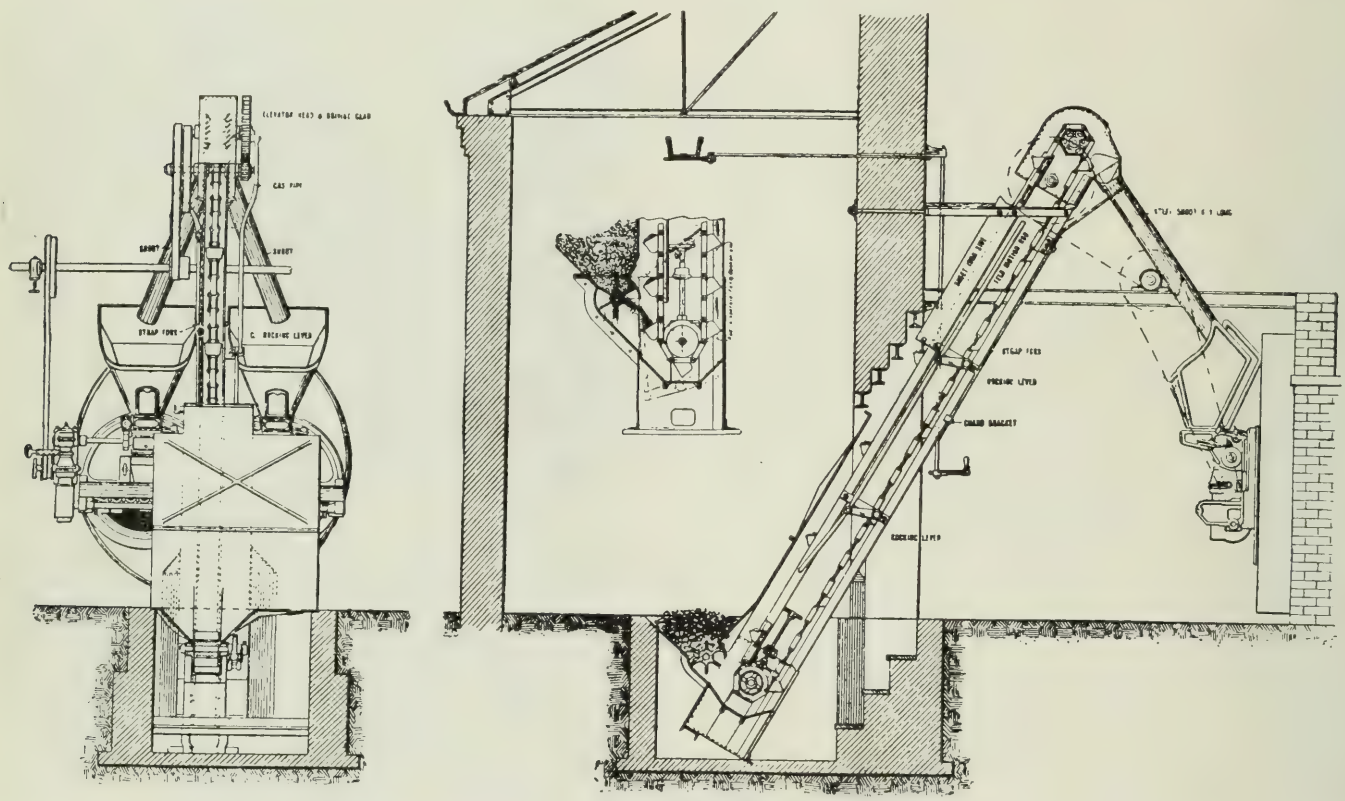
A Range of "Bennis" Stokers in the Boiler-House of the Alexandra Docks, Newport, Monmouthshire, England.

burned in all the naval battles of recent years, has been fired into a warship's furnaces by Royal hands, and has played its all-important part in the records won by leviathan liners."

The story of Newport's progress is worth reading, from the making of the first Newport dock of insignificant dimensions, and intended for coasting traffic, to the present time, when, as an ocean port of first importance, it demands attention and elicits admiration. Since 1905 it has been growing rapidly; 48 acres have been added to the deep water area, and a further 27 acres are waiting the admission of water as soon as the new deep water entrance dock is completed. This lock will be the largest of its kind in the world, measuring 1,000 feet long by 100 feet wide, with a depth of water on the outer cill at high water spring tides of no less than 45 feet, and 35 feet at high water neaps. Everything in connection with the lock will, as might be

expected, be on a comparatively colossal scale, including the gates and operating machinery. The completed portion of the dock is 3,700 feet long on the north side, while its maximum width is 1,050 feet. The south side of the dock is occupied by a concrete quay wall, a length of 2,250 feet having been equipped with a number of hydraulic cranes and an extensive transit warehouse, while the north side of the extension is equipped with four fixed coal hoists, erected on four concrete towers. The coal hoist structures rise to a height of about 100 feet above the coping of the piers; have a lift of 60 feet, and are capable of accommodating wagons of a gross weight of 23 tons, while provision has been made in the hydraulic cylinders to enable wagons up to 30 tons gross to be dealt with when required.

It is not intended to give here any detailed description of these huge docks, known as the Alexandra (Newport & South Wales) Docks and Railway. It is desired, however, to indicate the vastness of the undertaking which points to the enterprise of Viscount Tredegar, chairman of the Alexandra Docks Co., John Macaulay, Esq., general manager, and those associated with them in the scheme so ably carried out. As an instance of the care that has been exercised in all departments of the company's works to install only appliances best fitted to produce the desired results, mention must be made of the boiler-house. Steam is, of course, the "raison d'être" of every boiler-house, in spite of the fact that many boiler-house chimneys seem to suggest it is the emission of black smoke. In the boiler-house of the Alexandra Docks Company cheap steam is produced with the regularity of day and night. By cheap steam is implied steam that is manufactured from low-grade, low-price fuels, and that is steady and reliable in output. It must, moreover, be made without smoke. The accompanying illustration shows a range of five Lancashire boilers, fitted with "Bennis" stokers and self-cleaning compressed air furnaces manufactured by Ed. Bennis & Co., Limited, Little Hulton, Bolton, Eng., Canadian representative G. H. Tod, Toronto. The diameter of the flues in three of the boilers is 2 ft. 9 in., and in two of the boilers 2 ft. 11 in. The load carried is that of a hydraulic pumping station. Two tests were carried out here; one prior to the installation of the mechanical stokers, when the boilers were hand-fired; the other when the machines had been fitted. The latter was made on behalf of the Dock Company, by the staff of the British Engine, Boiler & Electrical Insurance Co., Ltd. The stoker-makers were represented. The duration of the tests was 7½ and 8 hours respectively. In the first trial three boilers were used; in the second trial two only were fired. The boilers are identical in design, with a diameter of 7 feet, and a length of 28 feet. The heating surface of each boiler is 823 square feet and the grate area 33 square feet, giving a ratio of heating surface to grate area of 24.94-1. Natural draught was employed in both tests. The fuel used was small Welsh coal, and there was no formation of smoke in either test. The draught at the back of the boiler for the stoker trial was 0.35 in., for the hand-fired trial it was not recorded. In the more recent test no attempt was made to press the boilers to their maximum capacity. One boiler only was kept at full power, while the second was regulated to suit the station load. Had the second boiler been brought up to the level of the first, the consumption of coal per square foot of grate per hour could have been raised to 30 lb., and still have shown good efficiency, with the fuel and draught employed. The comparison of the results of the two tests shows a substantial saving in the coal bill for the mechanical method, as the following statement makes clear. With the stokers the extra water evaporated, as from and at 212° Fah. per boiler per cent. was 84.3. The extra water evaporated, as



Alexandra (Newport and South Wales) Docks and Railway Co.

"Bennis" elevators lifting the coal to the shoots through which the fuel passes into the hoppers of the machine stokers. The elevators work in conjunction with the stokers, each is fitted with a rotary feed which renders choking of the buckets by over-supply impossible, and obviates any wrench from the chain.

from and at 212° Fahr. per pound of coal per cent. was 17.5, and the reduction in fuel costs per 10,000 lb. evaporated per cent. was 14.9. These results have been well maintained in actual practice.

THE DEVELOPMENT OF LOGGING MACHINERY.*

By R. E. Boehck.

Operations, generally known as "logging," are those parts of the lumberman's business connected with the cuting of the trees, their transportation and final delivery at the sawmill. They cease to be logging operations after the tree is in the mill, then the work of the millman begins. In the olden days when cities were few and small, there was little need for large lumber corporations such as exist to-day. Most of the lumber was cut by portable mills, in the following manner.

A small sawmill was rigged up in the forest and trees were cut down near the mill in a radius of perhaps a mile and were drawn to the mill by mules or horses. After a clearing was made, the mill would be taken down and moved along to another place about two miles away where it was again set up; these mills were small and their output no larger than the needs of the country demanded. Larger or stationary mills were, with very few exceptions, placed along the banks of rivers, and then a different method for logging was generally employed. The trees were cut and the logs assembled in various places along the river front. When, for instance, a long slope reached down to the water edge, a landing would be built near the bottom of the embankment and then after the slope has been cleared of trees, it would be used as a natural rollway, the logs being slid down to the landing where they were placed in high piles. This appears to be a very simple operation, but in most cases it was very hazardous and dangerous work. In this way the woods were partially cleared. Near the rivers the yield of timber was good, but further inland only the easy accessible places were worked and in different locations no attempt was made to reach the trees. There was little necessity to spend much time by going far from the river's edge, as timber was plentiful in those days. The mills were located near the river on some natural pond or small lake, which was connected with the river by a small canal. The river near the entrance of the canal was usually "dammed" and the logs coming down the river were guided through the canal into the logpond. There they would lie assembled, ready for use in the mill, sometimes several millions of them, comprising a year's work for a mill of average size.

After a while the logging machine made its appearance. It did not, however, change the method of logging for some time. It was used to replace horses and mules and do the work in less time. A portable hoisting engine was employed, provided with one drum. The engine was "anchored" to the ground, that is, fastened to a nearby tree or stump by means of a cable and the wire cable of the drum was drawn into the woods perhaps a thousand feet by several men, there to be fastened to a tree which had been cut down. Then the operator opened the throttle of the engine and the log was drawn toward it. This type of engine was called the "donkey engine"; it is still in use to some extent by smaller concerns, especially on the Pacific Coast.

The next step in advance was the development of a machine to simplify river logging. A powerful drum, driven by steam, was built and placed upon a barge or scow. The drum would hold perhaps a mile of heavy steel cable. The barge was fastened to the river's edge and the rope drawn into the woods. Several tongs were attached to the end of the cable. These machines would draw several logs at a time. This system has the name of pullboat logging. It increased considerably in value when Baptist cones came into use (which are wrought-iron cone-shaped contrivances, named after the inventor, fitted over the tongs on the end of the pulling rope.) As these cones glide easily over any reasonable obstruction in the way, they prevent the breaking of the cable through a blocking of the logs by obstruction.

Soon it became necessary to make such timberland, situated further away from the river, accessible, as the demand for timber became larger. This was done by the introduction of the logging railroad.

With the laying of tracks through the woods, it became necessary to find some way of loading the logs onto cars. This finally was accomplished when a logloader made its appearance. In the beginning this machine was a single drum affair, very simple and slow in its operation. Like most great inventions, it was lacking final perfection and development. It was placed on the side of the tracks. A location was chosen so that it was not more than a few feet away from a suitable tree, which was to serve as a mast. A cable was strung from the mast, at a height of perhaps 30 to 40 feet across the tracks, to the ground and was there fastened to a stump. This cable formed an incline for a pulley which was operated by the drum of the loading engine. Suspended from the pulley was a pair of tongs or slings which served as a means to fasten the log. This having been done, the pulley and log were hoisted upward on the incline until it was over the car. Then it was guided into place by a man on the car. Occasionally it would roll to the ground and the operation had to be gone through once more. In such a case the position of the man on the car was not enviable. A quick jump off the car to the side opposite that of the falling log was usually the only way out of danger.

A decided improvement in logging is the skidder. It bears this name because it drags or skids the logs on the ground toward the railroad. So far all the pulling out into the woods of the empty cable had to be done by hand or animal power. With a train waiting to be loaded and more logs needed by the mill, a way had to be found to do more work with the logging machine. This was finally accomplished by making a two-drum engine, where a larger drum with a heavy cable hauled in the load while a lighter cable on the other drum drew the empty cable into the woods. To accomplish this operation, a pulley is "shackled" to a tree stump, perhaps a thousand feet or more away from the engine. Over this pulley or sheave the lighter cable passes and is then fastened to the end of the hauling-in-cable. When a log is hauled in, the lighter cable travels along, unwinding from the drum until the log reaches the engine, it is stretched out to the pulley over it, and back to the engine again. After the log has been detached, it is wound up on the drum, pulling the heavy cable out toward the pulley. Then another log is attached to the heavy cable and the operation repeated. It can easily be seen that the lighter cable must be twice as long as the hauling cable.

In order to avoid too many logging railroads, very often a skidding machine is placed near the end of the reach of the first skidder cable, not far from the aforesaid pulley. This machine is generally known as the "yarder." Its duty consists of pulling logs to a place where they can be reached by the skidder, which in turn brings them to the railroad. In this way the line of operation can be extended by adding more yarders and the ground can be cleared from two or three miles on each side of the railroad. This is considered

*A paper presented at a meeting of the American Society of Engineer Draftsmen, held on 16th May, 1912, in New York City and St. Louis, Mo.

a good way, as it limits the number of logging tracks, and, of course, those that must be laid can be kept in better condition.

Still another type of logging machine is termed "Roading Engine." It is very similar to the ground skidder but is built for long hauls. It has exceedingly large drums, the main hauling cable being generally about 4,000 feet long. In using this type of engine, it is necessary to build a road for the logs to travel on. This road is mostly built from small trees, which otherwise have little value. A haul of 4,000 feet takes at the very least fifteen minutes. In order to gain time, the outhaul drum is geared up much faster, thus pulling back the empty cable is accomplished in about one-half of the time.

At this stage much had been accomplished and a great deal of heretofore unworkable timberland was opened. But all these machines were of little use in any place where the logs could not be drawn along the ground, like in swamps and over mountains. Some of our best timber, like cypress, spruce and hemlock, grow almost exclusively in swamps, while others, like pine, oak, etc., grow in rugged mountainous regions; therefore, after considerable experimenting, an entirely new method was introduced. Instead of drawing the logs along the ground, they were lifted high and carried clear of any obstructions toward their goal-line. This is done by the cableway skidder, which consists of a cable suspended between two supports, the headspar, part of or near the skidder, and the tailtree in the woods, from 700 to 1,000 feet away. Upon it travels what is termed the skidding carriage. The main cable, after passing over the tailtree, is fastened to a stump and is its own guy, with a similar arrangement on the headspar end of the cable. Provision is also made to take up the sag in the outstretched cable, either by a block and fall or by a separate drum on the engine. Two drums are required for logging, just as in the case of the ground skidder. The carriage is sent out into the woods, and when the desired log is reached it is attached to a pair of tongs or a sling on the end of the inhaul rope, which passes through a sheave wheel on the carriage. The carriage remains stationary, the outhaul rope holding is in place until the log is hoisted to the necessary height. Then the carriage is drawn in and the log is dropped near the skidder, handy for the loading engine to place on the waiting car. An improvement has been made on this type of skidder in late years, by adding a third drum the slackpulling drum, which takes up the unavoidable slack in the in-and-outhaul cable.

The advantages of such a cableway skidder, setting aside the fact that it is the only machine which can be used in swamps or mountains, are quite numerous, as only one headspar is required. With this as a centre, the ground is cleared at a radius from 750 to 1,000 feet, according to ground conditions and size of main cable employed. The tailtree, of course, has to be changed from time to time. As a rule it is more economical to have two main cables; while one is being used, the other is rigged up for the transfer of the carriage. This takes a few minutes and gives the engine operator time to oil the machinery. As soon as this is done, the logging operation may begin on the new line. While work is carried on there, the first main cable, now not in use, is being set up on another tailtree by a gang of men called the "riggers," and this will be ready for use when the logs along the cable which is in use have been removed. This operation is repeated until a circle around the skidding engine has been cleared, after which the machine is moved along to a new setting. In most cases the machine is permanently placed on a heavy steel car, with swinging axles, and on reaching the point where the setting is to be made, it is raised off the tracks by screw hydraulic jacks, then the axles are turned and the whole car placed on a set of temporary tracks at right angles to those of the logging railroad. In this way the skidding car is rolled off the logging tracks, staying parallel with them, but making room for the logging cars to pass. Thereafter the ropes are carried out and preparations are made for hauling the logs.

Another type sets the skidder high on a structure of either steel or wood, which straddles the track and leaves room for logging cars to pass underneath. This is not moved off sideways, as it is not in the way of cars. It is also provided with a set of jacks, generally four, and when it becomes necessary to move to the next setting, it is raised about six inches by means of the jacks, which leaves just enough room for a specially constructed car to run under. Then it is allowed to settle down on the car, the jacks pull up the remaining supports, and the machine is free from the ground, resting entirely on the car, ready to be moved by the locomotive to the next setting.

With all these developments of the skidder, it became important to improve also the loading apparatus. In other words, a loader had to be designed, capable of loading logs as quickly as they were skidded. If these two machines do not balance each other in efficiency and speed, the merits of one is naturally lost through the incompetence of the other, and therefore the loader had to be brought up to the top notch by various improvements. Several styles of loaders, distinctly different from each other, but equally efficient, are now in use. They have a swinging boom for loading, not unlike that of the well-known derrick. One type is built on a turntable, the boom itself does not raise or lower, it merely swings sideways, picks up a log and then swings back again over the track to the desired location, where the log is dropped.

Barring accidents and under average conditions, one of these modern skidding and loading outfits is capable of bringing from 40,000 to 50,000 feet of timber to the mill each day of ten working hours; higher figures have been reached in favorable territory. A sawmill with a daily capacity of 200,000 board feet of lumber would need four or five of these outfits to keep it supplied with logs at all times. The expense is only felt in the initial outlay, the operating expenses of a skidding plant being considerably lower than with any other method employed, and its advantages over other systems are numerous. By far the most important is the following one—it keeps the logs out of the water and therefore it keeps them clean, and clean logs bring with them a great saving in saws. If we realize that a steel band saw costs about $5,000, we understand what that means to the practical business man. By the old way of dumping the logs into a river, some of the best logs, extremely close fibred hard wood, would not float, but sink to the bottom, there to rot, and fortunes have been lost in this way by many lumber companies.

The conditions under which logging operations are carried on, vary greatly, one system may be well adapted for a certain location, but may be a failure elsewhere. The locality must be studied very carefully, and due consideration must be given to the kind and quality of the timber, the density of the trees, the condition and topography of the ground and what difficulties might arise in building a logging railroad; whether trestles have to be erected or rivers bridged. In some cases we may be confronted by a timber average of 2,500 feet per acre, while another may have 25,000 feet for the same amount of ground. It is clear even to the unexperienced that a very quickly and easily portable outfit must be selected to meet the conditions of the first case stated, as the machine will have to be on the go nearly all the time, not much timber being cut in each setting. Then again in mountains we would employ a different method from that

which we would use on level ground or in swampy land. The sawing of lumber is a detail easily arranged for, but the getting of the logs is a problem which requires ingenuity of a different sort. The locomotives must be sufficiently powerful to handle a number of cars, and at the same time not too heavy for the track and grades.

Very recently, in fact only a few months from the date of this writing, the General Electric Company has entered into the logging machine business as a competitor to the manufacturers of the steam engines by building electrically driven apparatus. Already they have installed a few outfits.

MAGNETIC OBSERVATIONS.

The subject of Terrestrial Magnetism has received a great deal of attention within recent years among the civilized countries of the world. Magnetic surveys are being conducted in several countries. The United States have now very complete information over their whole country and are able to publish a fine isogonic map. For some time past we have felt the need of such a map for the district covered by our own work and have received numerous enquiries from others for the same. This office is most advantageously situated to gather this information. Having a large staff of surveyors in the field every year, scattered over a large area, we are able to collect in a short time and at no additional expense a large amount of magnetic information. All surveyors employed by the day are required to take these observations. The magnetic needles now supplied are especially designed for this work and with few exceptions are very sensitive. Through the courtesy of Mr. R. F. Stupart, the director of the Meteorological Service, the compasses are all tested by the officer in charge of the Magnetic Observatory at Agincourt and the index correction determined. Where the needles are found to be anything but first class, a new compass is furnished the surveyor.

In the reduction of the observations to a common epoch we are very much handicapped by the absence of a magnetic observatory in the territory covered by the observations. Two of the staff of this division were placed at widely separated points in the Northwest this past season taking hourly declination readings for a whole month. These observations were afterwards plotted and compared with the daily photographic trace of the declinometer at Agincourt. Investigation of the results appear to show that the reduction of our declination observations by means of the Agincourt records is well worth the trouble, the precision of the resulting declination being apparently increased about two and one-half times. It is realized, however, that this is really not much more than a makeshift, and that what we require for proper reductions are the records of an observatory in the Northwest. This matter is now under consideration by the director of the Meteorological Service, who states that he may possibly be able to establish one there this coming season.

Declination returns for 1910, received to date	987

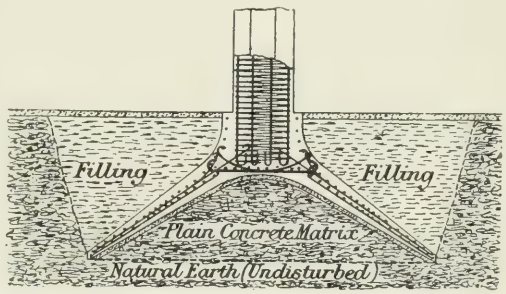
(From the report of the Topographical Surveys Branch, Department of the Interior).

HOLLOW-CONE FOUNDATIONS IN REINFORCED CONCRETE.

A novel method of constructing foundations in reinforced concrete has recently been devised by M. Considère, and described in London Engineering, which, it is claimed, shows considerable economy, both in material and in the cost of construction, over the ordinary methods now in use. The fundamental idea is the formation of a thin cone of reinforced concrete having a base area sufficient to limit the unit load on the ground to whatever figure may be thought desirable, the apex of the cone forming the point of support to the column itself. The amount of excavation for the foundation is also economized, as the earth beneath the cone is not disturbed, but is left roughly in the form of a pyramid. A glance at the illustration will, however, make clear the construction, the method of which is the following:—On the surface of the pyramid formed in the ground a few inches of plain concrete are deposited, and this forms the matrix for the cone of reinforced concrete. The cone is circular in plan, so that the thin covering of concrete has the form of an inverted saucer.

As an example of one of these cone foundations actually completed, one may be selected having on it the exceptionally heavy load of 612 tons in a newly-built boiler-house in France. The allowable pressure on the soil was 5,000 lb. per sq. ft., so that the required base area of the cone was 275 sq. ft., and the diameter 18 ft. 8 in. The angle of the generatrix of the underside of the cone with the horizontal was 30 deg.

It is hardly necessary to say that great care has to be exercised in designing these cones, for the vertical load from the column produces not only a bursting pressure on the cone, which varies in intensity from the apex to the circumference, and which has to be carried by a proper number of circular rings pitched at varying distances, but, in addition to the primary bursting effect, there is a compression varying also in intensity from the apex downwards, to withstand which the concrete must be of sufficient thickness at each point. Adequate concrete and steel must also be provided to prevent the column from perforating the top of the cone by shearing it through vertically. These considerations, however, do not affect the practical construction, which is simple, no temporary shuttering being required.



Sketch Showing Arrangement of Foundation in Place.

It is understood that although the method has been invented and perfected by M. Considère for only a short time, a number of important buildings have already been erected on these foundations, among them being a new dock warehouse at Havre, where the column loads are 195 tons; a boiler-house near Paris, with column loads of 612 tons; and a warehouse at Alexandria, with column loans of from 140 to 180 tons. All the English rights are controlled by the Considère Construction Company, Limited, 5 Victoria Street, Westminster, S.W.

CONSUMPTION OF PULPWOOD.

Over 95 per cent. of Canadian mills cut the pulpwood used by them from their own limits and consequently ross the wood themselves. Hence the given pulpwood consumption refers only to wood manufactured into pulp in Canadian mills, and includes only wood of domestic origin. There are seventeen mills on the lists of the Forestry Branch of the Department of the Interior from which no returns were received in 1910, but in nearly all cases these firms are newly incorporated or are known to be shut down, either temporarily or permanently. The quantity and value of the pulpwood industry, as compiled by Mr. H. R. Macmillan, may be considered a trustworthy estimate.

The fifty-one mills reporting used, in 1910, 598,487 cords of wood. There were exported in a raw state 943,141 cords, and for the first time pulpwood was imported into Canada to the extent of $49,322.

Although 23,642 cords of wood, or 3.8 per cent., less was used in 1910 than the year previous, the average price per cord has increased the value of the pulpwood industry by $121,074 over its value in 1909. The decrease in the quantity is due to the temporary closing of one or two large mills. This year the price of pulpwood recovered from the decline seen in 1909, when the price was only $5.57 per cord, and is about the same as in the year previous. The price was $6.07 in 1908 and in 1910 was $6. In 1910, also, 29,196 more tons of pulp were produced than during 1909, owing to an increase this year of some 145 lbs. in the amount of pulp produced per cord of wood.

Quebec is the premier pulpwood province of Canada because of its extensive spruce and balsam fir forests suitable for pulpwood, abundant and cheap water-power and plentiful supply of labor. The twenty-five mills in Quebec reported the consumption of 57 per cent. of the total for Canada, or 22,820 cords more than in 1909. Ontario likewise increased the amount consumed in its fifteen pulp mills by 23,200 cords, and used over one-third of the total consumption. The two provinces just named furnished over 92 per cent. of the total quantity of pulp. Nova Scotia consumed nearly 20 per cent. more than last year, while New Brunswick used barely one-fifth as much as in 1909. Thus Nova Scotia surpasses New Brunswick as a pulpwood province. New Brunswick in 1909 contributed 14.2 per cent. of the total; this year it was only 2.2 per cent.; this resulted mainly from the closing of one large plant. The province of British Columbia is still experimenting in pulpwood manufacture, and the negligible amount used in this province is for test purposes only.

Quebec is the one province in which the price of pulpwood was less in 1910 than 1909, the price falling off 35 cents per cord. The increase in the price of pulpwood throughout Canada is largely due to Ontario, in which province pulpwood was worth $7.02 per cord, or $1.30 more than during the previous year. Pulpwood was also more expensive this year in Nova Scotia and New Brunswick. Pulpwood from Nova Scotia, at $4.59 per cord, was cheaper than in any other province.

The decrease in the amount of pulpwood used in 1910 chiefly affected the use of spruce—45,800 cords less of this species being used in 1910 than in 1909. Although still over 75 per cent of the total pulpwood consumption, the proportion is gradually becoming less. In 1908 spruce formed 87 per cent. of the total, in 1909 83 per cent., and in 1910 78.6 per cent. The loss is all seen in New Brunswick, in which province 71,000 cords less of spruce was used this year than in 1909.

Balsam fir is a species of wood which is increasing in importance as a pulpwood. In 1910 twenty per cent., or 20,380 cords, more balsam fir was used than in 1909, and it is steadily gaining for itself a higher position among the important pulpwood species. In 1908 it formed 12 per cent. of the total, in 1909 16 per cent., and in 1910 20 per cent.

Another species which is gradually but surely becoming more important is hemlock, over five times as much being used in 1910 as during 1909. Hemlock was reported as a pulpwood for the first time in 1909, and this year it was used to a greater extent than poplar, thus becoming the third species in importance among pulpwoods.

The use of poplar fell off one-quarter, as only 3,608 cords of this wood were used in 1910. Jack pine has not been reported as a pulpwood since 1908. Before that time it was used considerably by two large mills, but has proven unsatisfactory.

The average price of the different species used is the cost to the mill-owner, and so includes varying logging expenses and a wide difference in transportation charges. A considerable proportion of the pulp-mill owners have their own timber limits, and to them the cost of pulp logs is merely the cost of carrying the limit and the transportation charges. Other operators buy in the open market and add transportation charges also.

Thus the prices quoted are the purchase price under different conditions and do not show the relative value of the different woods for pulp manufacture.

The effect of an excessive hauling distance is demonstrated in Ontario, where the price of spruce and balsam fir in 1910 was $7.01 and $7.22 respectively. The high price of balsam fir and the increased demand for this species proves its suitability for manufacture into pulpwood. Spruce was the most expensive species at $6.05, or 64 cents more than in 1909. During 1910 the price of balsam fir fell to the amount of 55 cents, to $5.71. Hemlock remained at about the same price for the two years and is still the cheapest species. In 1909 it was $4.51, and in 1910 $4.43. Poplar has increased 11 cents during the year, the price being $5.92 during 1910. The cheapest pulpwood bought was a small quantity of poplar in Nova Scotia, which cost $3 per cord. Balsam fir in Ontario at $7.22 was the most expensive wood used in Canada for pulping.

During 1910, no slabs nor sawmill waste was reported as being converted in woodpulp. This is an economy practiced in other countries, and by neglecting it Canada is losing greatly. It has been conservatively estimated that if all useful logs left in the bush by lumbermen, large-sized branches, slabs and other mill waste from the lumber industry in Canada had been conserved and converted into pulpwood in 1910, the annual output of pulpwood would have been increased, and not a single acre need have been cut over for logs to make wood-pulp only. During 1909, in the United States, 6 per cent. of the total pulpwood consumption was from slabs and mill waste. If economy had been practiced to the same extent in Canada during the year 1910, as much pulp might have been produced without cutting one additional pulp log as is manufactured from 36,000 cords of wood. This is considerably more pulp than Nova Scotia produced during 1910. The sooner such practical economy and utilization of waste commences, the longer will Canada have an adequate supply of pulpwood.

A PECULIAR ACCIDENT.

It is seldom that a steam engine fails to obey the action of the throttle, yet such was the fate of the steamer "Mildred" which, while approaching the lock gates of the canal at Buckingham, Que., became unmanageable and went over the dam. The water flooded the steamer, the boilers exploded and a cargo of cement was lost.

THE INTERNATIONAL ROADS CONGRESS OF 1913.

The third International Roads Congress will be held in London from Monday, June the 23rd to Saturday, June the 28th, 1913. These congresses will in future be held triennially. The first was held in Paris in 1908, and the second in Brussels in 1910. Their object is to collect, discuss, and circulate all the latest practical and scientific knowledge with regard to the construction and maintenance of highways. The congress of 1913 is held on the invitation of the British Government and is under the patronage of His Majesty King George V. The honorary presidents of the congress are the Right Hon. the Chancellor of the Exchequer and other members of H.M. Government, and the vice-presidents include the Right Hon. the Lord Mayor of London; members of both Houses of Parliament; Chairmen of County Councils; Mayors of Cities and Boroughs; presidents of learned societies, and of associations of local authorities, engineers, automobilists, cyclists, and of other organizations interested in the improvement of the roads. Over thirty Governments have intimated to the British Minister of Foreign Affairs their intention of taking part officially in the congress.

In view of the great advance effected in the methods of road construction and maintenance in recent years by the extension of the use of bituminous binding material, and the numerous experiments that have been made and data accumulated since the last congress, there is no doubt that the discussion of the various questions to be submitted to the congress will make the London meeting a notable event in the history of road engineering.

The two previous congresses aroused great interest among engineers, surveyors, automobilists, and manufacturers of road-making materials throughout the world, and a number of very valuable papers were contributed by the world's leading authorities on various subjects connected with the construction of roads.

Having regard to the rapid development of road construction in Canada these congresses cannot fail to prove of very great benefit and interest to those responsible for the good condition of the public highways in this country, and it is to be hoped that in view of the numerous opportunities for inspection of works and sites in England the number of Canadian delegates and members of the congress will be large.

The congress of next year will receive and consider a number of papers and reports by the leading authorities throughout the world on the maintenance of roads, their foundations and proper drainage, the prevention of dust and mud, the laying of light railways and tramways on roads, the choice of surfacing materials, the influence of weight and speed of vehicles on roads and bridges, the conditions that should be filled by horse or mechanically propelled vehicles in order that they may not damage or suffer damage from the roads, etc.

The chairman of the local Organizing Committee is Sir George S. Gibb, chairman of the Imperial Road Board. Sir Charles D. Rose, Bart., M.P., is treasurer, and Mr. W. Rees Jeffreys (secretary of the Road Board) is honorary secretary.

Excursions have been planned to various places of interest, including Windsor Castle, where His Majesty the King has intimated his intention of entertaining the delegates to afternoon tea. Receptions will be given to the members of the congress by the Lord Mayor and Corporation of the City of London at the Guildhall, by the committee of the Royal Automobile Club in their palatial premises in Pall Mall, and by the Institution of Civil Engineers in their new premises which they are now building at Westminster.

An exhibition of road machinery, materials and appliances used in road construction is being organized in connection with the congress, and in view of the fact that a very large attendance of foreign delegates is expected, in addition to engineers and surveyors from all parts of the United Kingdom, the exhibition will, it is expected, prove of great practical commercial value.

Membership of the congress is open to all, the individual membership subscription being £1, and that for associate members, i.e., wives and children, is 8/4.

Either of these subscriptions entitles the member to take part in all excursions and entertainments connected with the congress, whilst the full membership subscription entitles the subscriber, in addition to taking part in the proceedings of the congress, to receive the daily agenda published during the congress and a copy of the full report of the discussions and decisions, in addition to the complete set of the various papers on different subjects sent in by the members. As these papers comprise reports by leading authorities in all parts of the world, of experiments and recent data obtained in road engineering, etc., they are therefore of the highest value and interest.

Mr. W. Rees Jeffreys, the honorary secretary, is now in America endeavoring to secure a large attendance of engineers from this side. He arrived in New York on June 4th, and after spending a couple of weeks in the principal cities of the United States, will arrive in Toronto on June 27th. While in Canada he will visit Niagara Falls, Ottawa, Montreal and Quebec.

ENGINEERING OPPORTUNITY IN CHINA.

Rev Dr. T. E. Egerton Shore has received a cablegram from Dr. O. L. Kilborn in Chengtu, China, capital of the province of Szechwan, west China, asking that a teacher in mining engineering be secured for the Chinese Government School in Chengtu. This teacher will be supported by the Provincial Government at a salary of $2,100 (gold), together with traveling expenses each way—the salary to date from the time of arrival in Chengtu and the contract to be for a period of one year, with the probability of its extension beyond that time.

The cablegram states that this teacher is required at once and that a splendid opportunity presents itself from the standpoint of Christian influence in a government institute.

Dr. Shore will be glad to hear from anyone who may be interested in this opportunity. His address is the Methodist Mission Rooms, 33 Richmond Street West, Toronto.

THE LJUNGSTROM STEAM TURBINE.

The Ljungström turbine is the latest development in the field of steam turbines of the reaction type. As described in Engineering of London, it consists essentially of a radial flow machine. The steam is admitted between two disks, and in its passage from the centre to the circumference it passes between concentric blading rings carried alternately by the two disks. In the usual design both disks revolve, driving their shafts at equal speeds. To each shaft is coupled an electric generator. Since the relative speed of the blade is twice as great as in the standard reaction turbine of equal diameter and peripheral speed, equal efficiency may be obtained with only one-quarter as many rows of blades. Since there is no long casing with fixed blading, the risk of distortion trouble is largely eliminated. This also permits an almost unlimited degree of superheat, which, together with the reduction of gland and other losses, tends to give the machine a high efficiency.

PERSONAL.

MR. J. RUSSELL ELLIS has been appointed to the position of assistant engineer for the municipality of Regina.

MR. S. D. EGAN, of Toronto, has been appointed to the position of superintendent of the municipal railway system of Regina.

MR. W. H. ELSON has been appointed superintendent of two of the interurban divisions of the British Columbia Electric Railway, Limited, Vancouver, B.C.

MR. J. B. RANNIE has been appointed traffic agent of the British Columbia Electric Railway, Limited, Vancouver, B.C., in charge of the company's system in Vancouver and suburbs.

MR. ALLAN PURVIS has been appointed manager of the interurban lines of the British Columbia Electric Railway, Limited, Vancouver, B.C. The position of local manager of interurban divisions has been abolished.

COMING MEETINGS.

AMERICAN WATER WORKS ASSOCIATION.—June 3rd 8th. Annual Convention at Louisville, Ky. Secy., J. M. Diven, 271 River St., Troy, N.Y.

CANADIAN ELECTRICAL ASSOCIATION.—June 19th-21st. Annual meeting at Ottawa, Ont. Sec'y, T. S. Young, 220 King St. West, Toronto, Ont.

SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION.—June 26th-28th. Annual meeting at Boston, Mass. Sec'y, H. H. Norris, Cornell University, Ithica, N.Y.

ONTARIO MUNICIPAL ASSOCIATION.—Annual convention will be held in the City Hall, Toronto, on June 18th and 19th, 1912. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ont.

THE UNION OF CANADIAN MUNICIPALITIES.—August 27, 28 and 29. Meeting at City Hall, Windsor, Ont. Hon. Secretary-Treasurer, W. D. Lighthall, K.C.

CANADIAN PUBLIC HEALTH ASSOCIATION.—Second Annual Meeting to be held in Toronto, Sept. 16, 17 and 18.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE: Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, S. J. Chapleau, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving; Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, C. E. Cartwright; Secretary, W. Alan, Kennedy; Headquarters: McGill University College, Vancouver.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1290.

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydonejack; Meets every first and third Friday of each month, October to April, in University of Manitoba, Winnipeg.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION.—President, Chas. Hopewell, Mayor, Ottawa; Secretary-Treasurer, Mr. K W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm. Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, W. Sanford Evans, Mayor of Winnipeg; Hon. Secretary-Treasurer, W. D. Lighthall, K.C., Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, Mayor Mitchell, Calgary.; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALTIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang; Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, N. W. Ryerson, Niagara Falls; Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewit, General Manager Consumers' Gas Company, Toronto; J. Keillor, Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President, J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, D. McDonald, Manager, Montreal Street Railway; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, Killaly Gamble, 703 Temple Building, Toronto.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, F. S. Baker, F.R.I.B.A., Toronto, Ont.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman; Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, J. P. McRae; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Wm. Pierce, Calgary; Secretary-Treasurer, John T. Hall, Brandon, Man.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, 115 Phœnix Block, Winnipeg, Man. Second Monday, except June, July and August, at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc.
Printed forms for the purpose will be furnished upon application.

PLANS AND SPECIFICATIONS ON FILE.

The following Plans (P.) and Specifications (S.) are on file for reference only unless otherwise noted at the office of The Canadian Engineer, 62 Church Street, Toronto:—

Bids close — Noted in issue of

6-10—Electrical equipment, Vernon, B.C. .....(S.) 5-16
6-17—Electric Generating Station Equipment, Bassano, Alta. .....(S.) 5-30
6-10—Cement sidewalks, Maple Creek, Sask.(P & S.). 5-30

(Vernon specifications are on file at The Canadian Engineer Offices, Winnipeg and Montreal; Mather, Yuill & Company, Limited, Consulting Engineers, Vancouver, B.C.)

(Bassano specifications also on file at the office of The Canadian Engineer, Montreal, and the Engineers, Messrs. Bowring & Logan, 322 Donald St., Winnipeg).

(Maple Creek plans and specifications on file at The Canadian Engineer Office, Winnipeg, Man.)

TENDERS PENDING.

In Addition to Those in this Issue.

Further information may be had from the issues of The Canadian Engineer referred to.

Place of Work.	Tenders Close.	Issue of.	Page.
Bassano, Alta., electric generating machinery	June 17.	May 30.	74
Berlin, Ont., waterworks improvements		May 23.	72

TENDERS.

Battleford, Sask.—Tenders for the installation of a steam heating system for the Battleford Town Hall, will be received up to noon of June 10th, 1912. Plans and specifications can be seen at the Builders' Exchange, Winnipeg and Saskatoon, and at the office of J. P. Marshall, secretary-treasurer, Battleford.

Brantford, Ont.—Tenders will be received until noon of June 15th, 1912, for the furnishing of about 6,000 feet of reinforced concrete sewer pipe, varying in size from 30 inches to 45 inches. Specifications may be seen at the office of the City Engineer. T. Harry Jones, City Engineer, Brantford. (See advt. in The Canadian Engineer).

Kerrisdale, B.C.—Tenders for the supply of about 8 miles of steel pipes, varying in diameter from 4 to 18 inches, will be received until June 24th, 1912, by H. Floyd, Clerk Municipal Council, Kerrisdale, B.C. Particulars may be obtained at the office of the engineers, Cleveland and Cameron, 506 Winch Building, Vancouver.

Lachute, Que.—Tenders for the construction of an iron bridge over the North River, in the parish of St. Jerusalem, County of Argenteuil, will be received until June 10th, 1912. Plans and specifications can be examined in the office of J. E. Valois, secretary-treasurer, municipality of the council of the parish of St. Jerusalem, Lachute, Que.

Lawrenceville, Que.—Tenders for the construction of an iron bridge over the black river in the village of Lawrenceville, Que., will be received until the 15th of June, 1912. Plans and specifications can be examined at the office of Zoel Gervais, secretary-treasurer. municipality of village of Lawrenceville, Que., at which place tenders will be received.

Ottawa, Ont.—Tenders will be received up to noon of July 3rd, 1912, for the purchase of the Canadian Government steamer "Kestrel." Full particulars may be obtained from the Officer in Charge, H.M.C. Dockyard, Esquimalt, B.C. G. J. Desbarats, Deputy-Minister, Department of the Naval Service, Ottawa. (See advt. in The Canadian Engineer).

Ottawa, Ont.—Tenders for the construction of a public building at Kemptville, Ont., will be received at the Department of Public Works, Ottawa, until June 13th, 1912. Plans, etc., can be obtained at the post office, Kemptville, and at the Department, R. C. Desrochers, secretary.

Ottawa, Ont.—Tenders for the construction of a post office building at Maisonneuve, Que., will be received at the office of R. C. Desrochers, Secretary, Department of Public Works, Ottawa, until Monday, June 17th, 1912. Plans, etc., may be obtained on application at the office of Mr. C. A. Reeves, architect, 58 St. James Street, Montreal, and at the post office, Maisonneuve; also at the Department of Public Works, Ottawa.

Ottawa, Ont.—The Department of Public Works, Ottawa, will receive tenders until June 5th, 1912, for interior fittings, post office, Mount Forest, Ont. Plans, etc., to be seen on application to Mr. J. Hunter, Clerk of Works, Mount Forest, Ont.; Mr. T. A. Hastings, Clerk of Works, Postal Station F, Toronto, and at the Department of Public Works, Ottawa.

Ottawa, Ont.—Tenders will be received up till noon of Wednesday, July 17th, 1912, for industrial sites situate on an island lying east of the village of Caughnawaga, and joined to the mainland by the embankment of the Canadian Pacific Railway, and adjacent to the city of Montreal, containing 61.4 acres. Full information may be obtained upon application to Lorenzo Letournear, Assistant Indian Agent, St. Constant, Que., or to J. D. McLean, Assistant Deputy and Secretary, Department of Indian Affairs, Ottawa.

Ottawa, Ont.—Tenders for dredging required at Yarmouth, in the Province of Nova Scotia, will be received up to June 13th, by R. C. Desrochers, Secretary, Department of Public Works, Ottawa. Specifications can be obtained on application to the secretary.

Ottawa, Ont.—Tenders for the construction of a breakwater wharf at Carr's Brook, Colchester County, N.S., will be received by the Secretary of the Department of Public Works, Ottawa, until June 27th, 1912. Plans, etc., can be obtained at the Department and at the offices of H. A. Russell, Esq., District Engineer, Halifax, N.S.; E. G. Millidge, Esq., District Engineer, Antigonish, N.S., and on application to the Postmaster at Carr's Brook, N.S.

Ottawa, Ont.—Tenders for the construction of a pile bent wharf at Boswell, Division of Nelson, Kootenay District, B.C., will be received until July 2nd, 1912. Plans, etc., at the offices of G. A. Keefer, Esq., District Engineer, New Westminster, B.C.; on application to the Postmaster at Victoria, B.C., and the office of R. C. Desrochers, Secretary, Department of Public Works, Ottawa.

Ottawa, Ont.—Tenders for the construction of a drill hall at Gananoque, Ont., will be received by the Director of Contracts, Department of Militia and Defence, Ottawa, up to noon of June 22nd, 1912. Full particulars may be obtained at the offices of the Officer Commanding the 8th Field Battery, Gananoque, Ont.; the Officer Commanding the 3rd Division, Kingston, Ont., and the Director of Engineer Services, Department of Militia and Defence, Ottawa.

Port Arthur, Ont.—Tenders for paving on Cumberland and Algoma Streets will be received until June 24th, 1912. Further information, as to plans, etc., may be obtained from the City Engineer. J. J. Hackney, Commissioner Utilities, Corporation Offices, Port Arthur. (See advt. in The Canadian Engineer).

Regina, Sask.—Tenders will be received until noon of June 14th, 1912, for the supply of about 350 tons of reinforcing steed bars, 145 tons of R. I. joists, 6,000 barrels of Portland cement, and castings for the proposed Torhill Reservoir. Plans, etc., may be obtained from R. O. Wynne-Roberts, Consulting Engineer, Regina. (See advt. in The Canadian Engineer).

Regina, Sask.—Tenders for the construction of Torhill reinforced concrete circular reservoir and for works incidental thereto, will be received up to noon of June 21st, 1912. Plans, etc., may be obtained from R. O. Wynne-Roberts, Consulting Engineer, Regina. (See advt. in The Canadian Engineer).

Regina, Sask.—Tenders will be received up to June 15th, 1912, for the erection of a four-room brick school building at Buchanan, Sask. Plans may be secured from Messrs. Storey and Van Egmond, architects, Regina; and from H. P. Albert Hermanson, secretary-treasurer, Buchanan School District, Sask.

St. Thomas, Ont.—Tenders for the construction of sewers and for the supply of sewer pipe, will be received until June 19th, 1912. Specifications and plans can be seen at the office of the City Engineer. (See advt. in The Canadian Engineer).

Toronto, Ont.—Tenders for the terra cotta work, fireproofing and roofing of the new Government House, Chorley Park, Rosedale, Toronto, will be received up to noon of Monday, June 10th, 1912. Plans and specifications can be seen at the Department of Public Works, Toronto. H. F. McNaughten, secretary.

Toronto, Ont.—Tenders for steam heating, etc., in connection with the main drainage pumping station will be received up to noon of Tuesday, June 18th, 1912. Plans and specifications may be seen at the office of the City Architect, City Hall, Toronto. G. R. Geary, (Mayor), Chairman Board of Control, City Hall, Toronto.

Vancouver, B.C.—Tenders for the supply of the following pipe will be received until June 12th, 1912:—

10,000 ft. 24-in. inside measurement, steel pipe, 3-16 plate.
30,000 ft. 24-in. inside measurement, steel pipe, ¼ plate.
10,000 ft. 24-in. inside measurement, steel pipe, 5-16 plate.
4,000 ft. 18-in. inside measurement, flexible joint cast-iron pipe.

Plans and specifications can be obtained at the office of Messrs. Hermon & Burwell, Rm. 12, Inns. of Court, or at the office of James Stuart, Esq., City Purchasing Agent, City Hall, Vancouver.

Vancouver, B.C.—Tenders for the supply of 10,000 feet of 24-in. steel pipe and 4,000 feet of 18-in. flexible joint C.I. pipe will be received up to noon of June 12th, 1912, by James Stuart, City Purchasing Agent. Plans and specifications to be seen at the office of Messrs .Hermon & Burwell, Inns. of Court Building.

Victoria, B.C.—Tenders for the erection and completion of a large one-room schoolhouse at Diamond Crossing, in the Newcastle Electoral District, B.C., will be received up to noon of June 12th, 1912. J. E. Griffith, Public Works Engineer, Department of Public Works, Victoria.

Winnipeg, Man.—Tenders will be received up to noon of June 10th, 1912, for the construction of a Normal School in the city of Brandon. Plans, etc., may be seen at the office of the Provincial Architect, 261 Fort Street, Winnipeg, or on application to W. H. Shillinglaw, Esq., Brandon. R. P. Roblin, Acting Minister of Public Works, Winnipeg.

CONTRACTS AWARDED.

Brandon, Man.—Messrs. Geo. H. Archibald Co., Ltd., Winnipeg, are the contractors for the rebuilding of the Maple Leaf Milling Company's elevator, which was destroyed a short time ago by fire. The elevator will have a capacity of 120,000 bushels.

Calgary, Alta.—Contracts have been awarded for six new schools to be built in the city, the total cost of which will be $335,500. The following are the names of the builders to which each particular contract has been awarded: Sunalta school awarded to Doyle and Thomas, to cost $124,000; school on the Ramsey estate to T. R. Yeager, to cost $124,000; addition to the Victoria to J. A. McPhail, $63,000; Park Hill, J. A. McPhail, $15,500; two cottage schools awarded to H. Lougheed and H. Church, respectively.

Edmonds, B.C.—The contract for the extension to the high level reservoir on Capitol Hill, from which the entire water supply of the municipality is to be drawn, was awarded to Messrs. A. L. Olts & Co., of Vancouver, at $11,045.92; and the contract for the low level reservoir in D. L. 158, to supply River Road and South Burnaby generally, was let to G. H. Webster, of Vancouver, at $13,062.50.

Fredericton, N.B.—The Messrs. McVay have received the contract for the construction of an arch culvert over Lane's Creek, Carleton County. They have also secured the contract for the building of a new school building of concrete blocks at St. Andrews, the contract price being about $25,000.

Fredericton, N.B.—Contracts were awarded by the Quebec Contracting Company to sub-contractors for twenty-one miles of the work on the Saint John Valley Railway between Fredericton and Woodstock. The contracts are for the clearing, grubbing and grading, and are awarded as follows:—

To L. B. Smith and E. L. Merrithew, from mile 7 to 16½.
To Collins, Labelle & Prey, from mile 16½ to 20.
To W. and C. R. MacDonald, from mile 27 to 32.
To J. A. Wheaton & Son, St. John, from mile 32 to 35.

The contract for the construction of the fencing and telegraph lines between Fredericton and Woodstock has been awarded to T. R. Campbell, of Salisbury.

Fredericton, N.B.—Contracts for the construction and equipment of the Palmer-McLellan Shoepack Company's plant have been signed and calls for the expenditure of about $35,000. The John Palmer Company are also commencing operations for the construction of their new plant near the Hartt Boot & Shoe Company's factory.

Kerrisdale, B.C.—The Kerrisdale and Magee districts sewerage contracts has been awarded to Messrs. McLean & Co., at $156,000.

Barrett Specification Roofs

On the "Concrete City."

IN the illustration below, the Turner Construction Company of New York, has brought together in a scale drawing an accurate representation of most of the important modern concrete buildings which they have erected during the past nine years, at an approximate cost of $12,000,000.

It is an imposing display of best types of modern construction—"*a concrete city*" indeed—scientifically designed for maximum service at minimum cost and minimum maintenance.

It is significant that 95 per cent. of the entire roof area is covered with the Barrett Specification type of roofing. The figures are as follows:

Barrett Specification type of roofs	1,490,523 sq. feet
Plastic Roofings	14,714 sq. feet
Slate Roofings	21,640 sq. feet
Tile Roofings	5,619 sq. feet
Ready Roofings	38,381 sq. feet
Copper Roofings	6,355 sq. feet
All other kinds	7,448 sq. feet

It is important to remember that while all these buildings were constructed by the Turner Construction Company, the specifications were drawn by a large number of architects and engineers.

Barrett Specification Roofs were almost unanimously selected for one reason only, namely that they would give *better* service at *lower cost*, than any other roof covering.

Barrett Specification Roofs require no painting or similar attention—in other words, there are no maintenance costs. They will last upwards of 20 years without any care.

The superior economy of Barrett Specification Roofs justifies their adoption not only on big first-class concrete buildings, but on every flat roofed building from a tenement to a skyscraper—from a small mill to a modern manufacturing plant costing millions. But be sure it's a real Barrett Specification Roof. The only way to be sure is to incorporate The Barrett Specification in full in your plans.

Copy of The Barrett Specification free on request. Address our nearest office.

THE PATERSON MANUFACTURING CO., LIMITED

MONTREAL TORONTO WINNIPEG VANCOUVER ST. JOHN, N.B. HALIFAX, N.S.

Kincardine, Ont.—At a meeting of the County Road and Bridge Committee at Port Elgin, it was decided to award the contract for the reconstruction of the Denny's Bridge to Messrs. Hunter Bridge & Boiler Company, of Kincardine, their price being $7,800.

Newcastle, N.B.—The contract for the construction of the new Court House has been awarded to Messrs. John McDonald and Henry Ingraham, whose joint tenders was for $31,000, which includes wiring and plumbing.

Stratford, Ont.—The Stratford Bridge and Iron Company have been awarded the contract by the County Councils of Wellington and Grey, for the steel work of O'Dwyer's bridge at $1,875.

Toronto, Ont.—Messrs. J. E. Webb Co., General Contractors, Fisher Street, Toronto, have been awarded the contract for the building of the St. Lawrence Starch Factory at Port Credit. Main building is 480 x 100; five stories; brick stack, 150 ft. high; size inside of flue is 8 ft. square. The materials used are brick, concrete and steel.

Vancouver, B.C.—Messrs. Waterhouse, Church & Kerr, New York, have secured the contract for building the new Canadian Pacific Railway depot at Vancouver. It will cost $1,400,000. The company will also build a tunnel in the downtown section to relieve the conjestion of traffic. Railway crossings will be abolished and overhead bridges built, the whole involving a total of several million dollars.

Vancouver, B.C.—The Canadian Pacific Railway has awarded to Culletin Bros., of Spokane, a contract for the construction of ten miles of the east coast division of the E. & N. Railway, on Vancouver Island. Their work will extend north from McBride Junction near Nanaimo. Another ten-mile section from Courtenay south, in the direction of Campbell River, was recently let to Mr. C. E. Hoard, of Victoria. Between this contract and the Culletin work is a gap of sixty miles, the construction of which will likely be undertaken later in the year.

Vancouver, B.C.—Messrs. Kelling & Co., have been awarded the contract for heating four schools in this city, the tender submitted being $26,500.

Vernon, B.C.—The contract for the construction of approximately 50,000 feet of combined sidewalk and curb, has been awarded to Messrs. B. C. Craintoid, Ltd., of Vancouver, for $13,394.50.

Walkerton, Ont.—The Saugeen Electric Light and Power Company, and the Walkerton Light and Power Company, have awarded the contracts for the repairs on the Southampton dam, and also on the one at Walkerton, both of which were put out of commission by the spring floods. The weir at Southampton is to be completed in ten weeks, and the one here within three months. The owners of both dams are Messrs. Robertson and Roland, of Walkerton. The probable loss at Walkerton is about $10,000, and at Southampton $5,000.

RAILWAYS—STEAM AND ELECTRIC.

Saskatoon, Sask.—The municipal council have decided to present a by-law calling for the construction of a street railway to the ratepayers for decision. The Stone and Webster Engineering Corporation have made an offer to construct the line and finance the same for the period of twelve months in exchange for civic bonds to the value of $500,000.

LIGHT, HEAT AND POWER

Barrie, Ont.—The ratepayers voted in favor of the hydro-electric by-law which called for an expenditure of $7,000.

Kingston, Ont.—Mr. R. S. Kelch, of Montreal, is preparing a report for the municipal council on the power question, and will have the same ready for presentation in the course of a few days.

Moose Jaw, Sask.—The city of Moose Jaw has accepted the proferred assistance of Saskatoon, and the council have asked for the plans of Saskatoon's new power house. R. M. Thompson, who was responsible for the plans of the new building, will go into the matter there with the city council of Moose Jaw. Meantime with the assistance of machinery supplied by the Robin Hood Milling Co., of that city, a limited amount of power is being obtained to give the city a partial water supply, and to care for the absolute necessities requiring electrical power. It is understood that the city will go ahead at once with the construction of a new power plant.

Scotstown, P.Q.—The power plant of this municipality was swept away when a dam belonging to the Emberton Lumber Company gave way.

GARBAGE, SEWAGE AND WATER.

Berlin, Ont.—The ratepayers will be asked to vote on a proposed expenditure of $100,000 on a new sewage system. Mr. Peiper is chairman of the Municipal Sewage Committee.

Exeter, Ont.—The ratepayers voted in favor of spending the sum of $5,000 for improvements of the sewage system.

Fort William, Ont.—Mr. T. Aird Murray has recommended that a new 24-inch main be constructed immediately to the reservoir. The cost of this will be about $75,000. Other improvements to the water supply which he has suggested will cause an expenditure of about $350,000 if carried out as he has planned.

Moose Jaw, Sask.—A large pump, the property of the Saskatchewan Flour Mills, has been installed in the pit of the old power plant and is giving a satisfactory service. The supply is being taken from the Moose Jaw River and forced through the filter beds before entering the mains.

Simcoe, Ont.—The ratepayers voted their approval to the expenditure of $36,000 for a sewage system.

Vancouver, B.C.—The Municipal Board of Works received tenders for the construction of lateral sewers on Twelfth, Thirteenth, Fourteenth and Fifteenth in the vicinity of Oak and Yukon Streets, as follows:—

Romano Pinto & Co.	$31,500.00
LaPlaca Brothers	22,479.00
Ledingham & Cooper	32,746.00
McGarry Company	29,000.00
Kennedy Brothers	28,849.00
D. A. Anderson	22,778.95
David Timiro	21,097.80
Bruce & Ford	39,900.00

The tenders were all referred to the City Engineer for report.

BUILDINGS AND INDUSTRIAL WORKS.

Calgary, Alta.—Applications for the erection of three apartment houses are being considered by the municipal architect. The owners of the buildings are Mr. George Calhoun, Mr. J. W. Dafoe, and Messrs. Scott and Hartfront. The total cost of these buildings will be about $140,000.

Creston, B.C.—The Canyon City Lumber are making arrangements for a plant to manufacture small fruit boxes. Mr. D. W. Briggs, of Portland, Oregon, is president of this company.

Fort William, Ont.—The management of the Benson Starch Works of Edwardsburg, are considering the erection of a plant on Island No. 2 near this city.

Fort William, Ont.—The management of the Great Wire Fence Company of Winnipeg, have opened negotiations with the Industrial Bureau that may end in the erection of a plant in this city.

Hamilton, Ont.—The Steel Castings Syndicate will erect a $300,000 plant in this city. C. W. Sherman, of Buffalo, N.Y., is the manager of this new concern.

Lethbridge, Alta.—Messrs. C. Roy Strotz & Company, of Winnipeg, have had preliminary work commenced in the matter of erecting a factory in this city.

Moose Jaw, Sask.—The plans of the proposed Young Women's Christian Association Building, show a four-story building of brick and stone.

Port Arthur, Ont.—A report states that certain interests are making preparation for the erection of a ten-story office building.

Saskatoon, Sask.—The management of the Queen's Hotel have had plans prepared for alterations which will make their building five stories in height.

Sherbrooke, Que.—The Jenckes Machine Company have decided to enlarge their plant. The additions consist of a ma-

48 in. CONTINUOUS STAVE LINE.

ROYCE CRANE TYPE MOTORS

ARE BETTER SUITED FOR THE PURPOSE THAN ANY OTHER MOTOR.
Thousands are at work on ROYCE CRANES in all parts of the world.

ENGINEERS! Compare the following details with what you are using, and THINK IT OVER:—

Armature fitted with a short stiff shaft of high carbon steel, which can be removed and replaced without disconnecting the commutator.
Phosphor bronze bearing bushes fitted on all sizes of motors (bushes are interchangeable).
Field coils can be removed without removing armature and disturbing gearing.
One size of carbon brush and brush holders to all sizes of motors from 3 to 60 B.H.P.
Oil throwing impossible. Ball bearings supplied if required.
Armature and field coils impregnated under vacuum.
Every motor tested totally enclosed for 30 minutes, and temperature rise will not exceed 32 degrees Centigrade, and while still hot receives high voltage test.
All parts extremely accessible; *just what you want for crane motors!*

Your enquiries are solicited for
MOTORS, CRANES, TELFERS, CAPSTANS, WINCHES.

ROYCE, LTD. **Trafford Park, Manchester, England**
Canadian Office - 207 Lumsden Bldg., TORONTO.

chine shop, 300 x 50 ft., and a boiler shop 300 x 60 ft. It was announced some time ago that one new shop would be built, but the company has now decided to build two shops.

Stratford, Ont.—The management of the R. M. Ballantyne Company have approved plans which will enlarge the present factory to double capacity.

Toronto, Ont.—Messrs. H. P. Eckardt & Co. will erect a six story warehouse at a cost of $75,000.

Toronto, Ont.—There is a probability of the congregation of the Kew Beach Presbyterian Church erecting a new church building or enlarging the present structure.

Waterloo, Ont.—The ratepayers voted in favor of a by-law granting a loan of $10,000 to Chas. Kreutzger, for the erection of a box factory.

Welland, Ont.—The management of the Welland Machine & Foundries are preparing plans for an enlargement of their plant.

Welland, Ont.—Plans are prepared for extensive additions to the Page Hersey pipe mills, consisting of a large addition to the tube plant and the construction of a pattern shop and a pattern storage building.

West Toronto, Ont.—The management of the Russell Motor Car Company have had plans prepared for the erection of a four story machine shop, 170 x 60. The cost of this work is estimated at $100,000.

West Toronto, Ont.—The management of the Canada Foundry are erecting a plant for the manufacture of ornamental iron work.

Weyburn, Sask.—The Saskatchewan Creamery Company has had plans prepared for the erection of their plant.

BRIDGES, ROADS AND PAVEMENTS.

Barrie, Ont.—The ratepayers voted in favor of spending the sum of $25,000 on the construction of permanent roadways.

Greenfield Park, P.Q.—The council of this municipality, which is near Montreal, will co-operate with the parish of Longueuil in the construction of a permanent highway under the Good Roads Act.

Ottawa, Ont.—The Deputy-Minister of Railways and Canals, Mr. A. W. Campbell, has suggested that the Ottawa East bridge be removed, should a new structure be erected across the canal.

Trail, B.C.—The new steel bridge erected across the Columbia River at this point has been finished, and is now open to the public. This bridge is a portion of the highway now being constructed to Christina Lake, and when this is completed a very fine scenic district will be open to tourists.

Vancouver, B.C.—The Board of Works received tenders for street paving as follows: wood block pavement on Cambie Street, Robson to Smythe:—

Romano Pinto & Co.	$7,900
LaPlaca Brothers	7,867
B. C. Granitoid Company	8,113
McAdam Construction Company	7,400
Delbridge & Peterson	7,510
Ledingham & Cooper	7,994
T. R. Nickson & Co.	8,150

Wood block pavement on Homer Street, Pender to Smythe:—

McAdam Construction Company	$43,000
Delbridge & Peterson	43,545
Ledingham & Cooper	46,279
T. R. Nickson & Co.	44,125
LaPlaca Brothers	46,673
Romano, Pinto & Co.	45,650
British Columbia Granitoid Company	46,447

Stone block pavement, lane east of Granville Street from Davie to Pacific:—

T. R. Nickson & Co.	$10,991
Ledingham & Cooper	10,200
B. C. Granitoid Company	10,910
LaPlaca Brothers	10,208
Romano Pinto & Co	10,440

The City Engineer will report on these.

Windsor, Ont.—The ratepayers endorsed the by-laws calling for the expenditure of $30,000 for new sidewalks and $1,700 for the erection of a new public lavatory.

FIRES.

Moose Jaw, Sask.—The municipal power house was destroyed by fire. The property is valued at $242,587.

Saskatoon, Sask.—A fire which broke out in the offices of the telephone exchange caused considerable financial loss to the telephone company.

Wainwright, Alta.—$75,000 damage was caused to the business section of this town by fire.

CURRENT NEWS.

Bassano, Alta.—An order has been placed from Calgary for 60 miles of pipe to be used in conveying natural gas from the wells at Bow Island to the city. It is expected that the gas will be available in the city about July 1st.

Eastern Canada.—The Commissioners of the St. John and Quebec Railway have purchased a motor boat and an automobile for the use of the surveying parties working on the lines of this railway.

Medicine Hat, Alta.—The municipal Engineering department have completed plans for a subway to be constructed under Toronto Street, and the council are giving the matter serious consideration. The Board of Works will consult with the officials of the Canadian Pacific Railway in the matter.

Red Deer, Alta.—The ratepayers will vote on a by-law calling for the expenditure of certain sums to provide a motor combination wagon fire hose and other fire fighting equipment.

Toronto, Ont.—The municipal Hydro-Electric Department have opened a store in the business section of the city for the purpose of demonstrating electrical appliances for use on the current supplied by the city.

TRADE ENQUIRIES.

The following were among the inquiries relating to Canadian trade received at the office of the High Commissioner for Canada, 17 Victoria Street, London, S.W., during the week ending May 18th, 1912:—

A London firm who specialize in certain paint oils desire to appoint Canadian agents. A member of the firm will be in Montreal and Toronto in June, and could interview interested parties.

A Liverpool firm desire to be placed in communication with Canadian manufacturers of lump charcoal.

A Glasgow firm would like to hear from Canadian buyers of pumice stone and pumice powder.

A Scottish correspondent is in the market for supplies of clean tin cuttings such as are produced in die stamping from sheet tin.

A London firm make inquiry for the name of the Canadian manufacturer of "Ontario" cotton duck.

The following were among the inquiries relating to Canadian trade received at the office of the High Commissioner for Canada, 17 Victoria Street, London, S.W., during the week ending May 24th, 1912:—

A Birmingham firm of consulting and inspecting engineers are open to act for Canadian firms who may be placing orders in Great Britain for machinery and engineering appliances generally.

The Hamburg branch of a London merchant firm desire to get into touch with Canadian bran shippers, especially those represented in Europe.

A Hamburg firm desires to import linseed from Canada, and would like to hear from shippers in the Dominion.

From the branch for City Trade Inquiries, 73 Basinghall Street, E.C.:—

A North of England company manufacturing ready-made bungalows and other buildings wish to extend their trade to Canada.

A London firm of chemical merchants ask to be placed in touch with Canadian manufacturers of acetic acid, of which they seek supplies. They are also interested in acetone, and any other chemical products suitable for the English market.

A London company who are in the market for supplies of white enamelled cornice poles, and also of rings, and ball and spear ends to suit, invite samples and quotations from Canadian manufacturers.

THE TRIPLEX BLOCK

A Triplex Block hung from a temporary rigging and used for laying pipe.

What is the Life of a Triplex Block?

WE don't know. Triplex Blocks built by the Yale and Towne Co. at the very beginning—twenty-five years ago—are still in actual use. The Triplex Block of to-day possesses greater lasting powers. With its steel parts—its chain superior to any other—its non-wearing gear movement—and the guarantee of a rigorous test before shipment under a fifty per cent. overload. It will outlast the man who buys it, no matter how young he may be.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from The Canadian Engineer for small fee.

16477—May 9—Directing G.T.R. to within 90 days from date of Order install improved type of electric bell at crossings of Ontario and Erie Sts., Stratford, Ont., 20 per cent. from Railway Grade Crossing Fund.

16478—May 9—Approving location of Algoma Eastern Ry. Station at Espanola, in Twp. of Merritt, Ont. Rescinding Order 16426, April 12, 1912.

16479—May 10—Directing that in Canadian Freight Classification the following articles be transferred from their present positions to the 'Musical Instruments List," and that they be also included in the second-class rating applicable to "Musical instruments, all kinds, not otherwise specified, carloads, minimum 12,000 pounds," namely: gramaphones graphophones, phonographs, records; application, Berliner Gramophone Co., Montreal, Que.

16480—May 7—Approving location of G.T.P. Ry. station to be erected at mileage 119 east of Prince Rupert, B.C.

16481—May 8—16482—May 10—Granting certificates to G.T.P. B.L. Co. correcting errors in right-of-way plans Biggar-Calgary Branch, etc.

16483—May 8—Approving location of Algoma Central and H.B. Rys. terminal station at Sault Ste. Marie, Ontario.

16484—May 9—Authorizing C.N.O. Ry. to cross two highways in Twps. of Clarendon and Litchfield, County Pontiac, Que.

16485—May 9—Authorizing C.N.R. to cross and divert highways in city of Moose Jaw, Sask.

16486—May 8—Approving location of James Bay & Eastern Ry. (C.N.R.) station grounds at St. Prime, Que.

16487—May 10—Approving location of Kettle Valley Ry. Co. from mileage 65 to 76, northwest of Midway, B.C.

16488—May 6—Authorizing C.P.R. to take lands for purpose of diverting Scarlett Rd. and St. Claire Ave., Toronto, Ont.

16489—May 8—Extending until Oct. 16, 1912, time for completion by C.P.R. of siding for city of Moose Jaw, Sask., authorized by Order 15115, Oct. 16th, 1911.

16490—May 9—16491—May 7—Authorizing Campbellford, Lake Ont. & Western Ry. (C.P.R.) to construct its Glen Tay to Cobourg Line at mileage 24.8 from Glen Tay, across tracks of Kingston and Pembroke Ry., interlocking plant to be installed; and at mileage 88.09 over tracks of Central Ontario Ry. in town of Trenton, Ont., by overhead structure.

16492—May 6—Approving location of G.T.P. B.L. Co. station at mileage 25, Cutknife Branch, Saskatchewan.

16493—May 7—Relieving C.P.R. from further protecting crossing third west of Kemptville Jct., Ontario.

16494—May 2—Appointing William Barrett, Judge of the County Court of County of Bruce, Referee, to fix amount of damages sustained by claimants re overflow of Saugeen River caused by bridge of Walkerton & Lucknow Ry. Co. (C.P.R.) at Walkerton, Ont.

16495—May 10—Relieving Vancouver, Victoria & Eastern Ry. from erecting and maintaining fences from Laurier to Danville, B.C.

16496—May 11—Authorizing C.P.R. to construct spur for Cockshutt Plow Co., Ltd., at Regina, Sask.

16497—May 10—Directing that no cars be allowed to stand on any siding within at least 50 ft. of crossing of C.P.R. at Neepawa, Manitoba.

16498—May 10—Approving revised location of G.T.P. B.L. Co. station grounds at Bashaw, Alberta.

16499—April 13—Authorizing G.T.P. Ry. to construct "wye" in Sec. 5, Twp. 42, Range 24, west 3rd M., at mileage 600, Sask.

16500—May 11—Authorizing Midland Ry. of Canada (G.N.R.) to join its industrial spur tracks with industrial spur of C.P.R. leading to works of Canada Malting Co., Ltd., Winnipeg.

16501—May 10—Directing Brandon, Sask., and H. B. Ry. (G.N.R.) to construct transfer tracked to connect with C.N.R. at Minto, Manitoba.

16502—May 11—Authorizing C.P.R. to construct 5 branch lines or spurs for the Dryden Timber & Power Co., Ltd., Dryden, Ont.

16503—May 13—Directing that G.T.P. Ry. be subject to a penalty of $100 per day from date of this Order that work required by Order No 15735 of January 2nd, 1912, remains uncompleted.

16504—May 13—Extending time for commencement of construction of subway until June 15th, 1912, by city of Montreal, over C.P.R. at Park Ave. Order 16359, April 23, 1912.

16505—May 13—Approving revised location of G.T.P. B.L. Co. Regina-Moose Jaw Branch, mileage 0 to 2.1, Saskatchewan.

16506—May 13—Extending for 30 days from date of this Order time for completion of siding authorized by Order 15317, Nov. 10th, 1911, G.T.R.

16507—May 13—Approving Victoria & Sidney (G.N.R.) Ry.'s Std. Freight Tariff of Maximum Tolls in British Columbia.

16508—May 13—Authorizing C.N.R. to construct bridge across Bow River on its Calgary-Vegreville Extension.

16509-10—May 13—Approving revised location of C.N.O. Ry. (Ottawa-Capreel Line) through Twp. of Field, Dist. of Nipissing, mileage 254.53 to 256.2 from Ottawa; and C.N.O. Ry. (Sudbury-Port Arthur Line) through unsurveyed territory in the Dist. of Thunder Bay, mileage 399.21 to 404.46, from Sudbury Junction.

16511—May 11—Authorizing C.N.O. Ry. to cross 6 public roads in Twp. of Foley and McDougall, Ontario.

16512—May 13—Authorizing C.P.R. to construct spur for W. T. Rawleigh Medican Co., Winnipeg, Manitoba.

16513—May 10—Enjoining C.N.R. from interfering with road allowance authorized by Order 14440, July 28, 1911, and to drain borrow pits within 30 days, under penalty of $10 per day, on farm of David Hay, Kinnoull, Alberta.

16514—May 14—Naming delivery of city of Kelowna, B.C. (Express).

16515—May 11—Authorizing G.T.P. B.L. Co. to construct its Tofield-Calgary Branch across highway at mileage 30.

16516—April 10—Approving location of Campbellford, Lake Ontario & Western Ry. (C.P.R.), Glen Tay to Cobourg line, from mileage 58.5 to 68.

16517—May 11—Authorizing C.P.R. to construct spur for Eddy Bros. & Co., Ltd., at Blind River, Ontario.

16518—May 13—Directing that no car or locomotive be allowed to stand on siding, crossing King St., or at Nipissing St., within 50 ft. each way, at Sturgeon Falls, Ont., C.P.R.

16519—May 13—Directing C.P.R. to within 90 days from date of this order install electric bell at Wilson Street, about 1 mile north of Perth Station, Ontario; 20 per cent. from Railway Grade Crossing Fund.

16520—May 15—Restraining C.N.R. and Midland Rly. Co., (G.N.R.), under penalty of $100 after May 20, 1912, from carrying out any provisions of agreement prior to its sanction by the Governor-in-Council upon recommendation of the Board. Re operating of trains of the Midland and G.N.R. Co.'s from International Boundary to Winnipeg, Man., over C.N.R.

16521—May 13—Authorizing municipality of Cap de la Magdeleine to construct highway over C.P.R. at Boulevard Forget.

16522—May 14—Authorizing C.N.O. Ry. to cross by overhead structure public road between Lots 10 and 11, Con. 2, Ottawa, Front, Twp. Nepean, Ont.

16523—May 13—Approving location of C.P.R. station at Springside, Sask.

16524—May 13—Relieving C.P.R. from further protection of crossing at North Glencoe, Windsor Subdivision, Ont.

16525—May 14—Refusing application of K. and P. Ry. for approval of plans, etc., of Godfrey Station, Ontario.

16526—May 14—Directing that C.P.R. construct farm crossing pending completion of public crossing for John Brill, of Boulder and Harry Sawyer, of Revelstoke, B.C.

16527—May 15—Approving Standard plan for 20-foot arch of St. John & Quebec Rly. Co.

16528—May 15—Approving G.T.P. Standard Freight Mileage Tariff, C.R.C., No. 9, to apply from Prince Rupert east, 170 miles, to Carnaby, B.C.

16529—May 15—Extending until 1st September, 1912, time for installation of interlocking plant near Chaudiere Jct., by C.N.R., near Ottawa, Ont.

16530—May 15—16531—May 14—Authorizing C.N.O. Ry. to construct bridge over Duchesney Creek, in Twp. of Commanda, Dist. of Nipissing, and across Little Sturgeon River, Twp. of Beaucage, District of Nipissing, mileage 243.5 from Ottawa.

16532—May 13—Approving location of Campbellford, Lake Ontario and Western Ry. (C.P.R.) at mileage 79.5 from Glen Tay to westerly boundary of town of Trenton, Ont.

16533—May 14—Approving location of C.P.R. station at Jaffray, B.C.

16534—May 15—16535—May 14—Authorizing C.P.R. to reconstruct Red River Bridge, Winnipeg Terminals, and bridge 57.1 on its Cascade Subdivision, B.C.

16536—May 14—Directing C.P.R. to within 90 days to install electric bell at crossing 1¼ miles west of Claremont, Ont. 20 per cent. from Railway Grade Crossing Fund.

16537—May 17—Approving changes and alterations in vicinity of Dufferin Bridge in the city of Ottawa, by C.P.R.

16538—May 17—Authorizing G.T.R. to construct spur for British Canadian Canners, Ltd., Bowmanville, Ontario.

16539—May 15—Authorizing C.P.R. to construct two spurs for Western Canada Flour Mills Co., town of Goderich, Ont.

16540—May 17—Authorizing Guelph Radial Ry. to cross C.P.R. on York Road, Guelph, Ont.

16541—May 17—Directing G.T.R. to within 90 days install electric bell in village of Lynden, Ont. 20 per cent. from Railway Crossing Fund.

16542-43—May 18—Authorizing C.P.R. to reconstruct bridge No. 5.7 on Kippawa Subdivision, Lake Superior Division, and to use and operate bridges 10.4 and 36.5, Farnham, S.D.

16544—May 15—Approving location of Windsor, Essex & Lake Shore Railways new siding, freight shed and station at Essex, Ont.

16545-46—May 18—Authorizing G.T.R. to construct siding for Bechtels, Ltd., near Waterloo, Ont., and for St. Lawrence Starch Co., Ltd., at Port Credit, Ont.

16547—May 20—Authorizing C.P.R. to construct spur for Ontario Rock Co., Ltd., Twp. of Belmont, Ct. Peterboro, Ont.

16548—May 20—Authorizing C.P.R. to reconstruct bridge 94.8, Moose Jaw, S.D. Rescinding Order 15687, December 27, 1911.

16549-50—May 20—Recommending to the Governor-in-Council agreements between C.N.R. and Midland Rly. Co., of Manitoba, (G.N.R.), for operation as joint section from International Boundary to Woodward Avenue, Winnipeg, Man., and permitting above-named companies to operate joint section for thirty days from date when if not approved by Governor-in-Council permission shall cease.

16551—May 20—Approving location of Central Railway Co. of Canada from C.P.R. line near McAlpine station at mileage 7.2 to G.T.R. line near South Indian Station at mileage 38.165, County of Russell, Ontario.

16552—May 21—Authorizing Joseph Battle, Thorold, Ont., to construct chute underneath G.T.R., Stuart St. Station Yd., Hamilton.

16553—May 20—Directing G.T.R. to install electric bell at crossing of 3rd Con. in Twp. of Stamford, Ont. 20 per cent. from Railway Grade Crossing Fund, to be installed by Aug. 1st, 1912.

16554—May 20—Approving location of Kettle Valley Ry. Co., from mileage 4.80 to 19.56, and 19.56 to 38.99, west of Penticton, B.C.

16555—May 20—Authorizing Vancouver & Lulu Island Ry. (C.P.R.), to construct second track across 11 roads and streets in municipality of Point Grey, Province of British Columbia.

16556—May 17—Refusing application of Canadian Press, Ltd., requiring G.N.W. and Western Union Tel. Co., to provide special tolls for press service similar to C.P.R., and directing C.P.R., G.N.W., and Western Union to restore the rate of 25c. per 100 words for "Press Specials" in the Maritime Provinces, effective by 17th June, 1912.

16557—May 21—Authorizing G.T.R., G.B. & S. Ry. (C.P.R.), and C.N.O.R. to operate trains over interlocking plant at Atherley Jct. without stopping account interlocker completed.

16558—May 20—Approving express collection and delivery limits for town of Grand Falls, N.B.

16559—May 20—Directing G.T.P. B.L. Co. to place crossing on Mr. E. D. Sworder's property at Balcarres, Sask., in proper condition for tram traffic; penalty, $25 after June 30th, 1912.

16560—May 21—Authorizing C.P.R. to divert Government Road on its Waldo Branch at mileage 9.92, British Columbia.

16561—May 20—Authorizing C.P.R. to reconstruct bridges 66.77, 19.7 and No 6 on Cartier, S.D., Havelock, S.D., and on Orford Mountain Branch, Eastern Division.

16562—May 21—Authorizing James Bay & Eastern Ry. (C.N.R.) to construct bridge across River a l'Ours, in Township of Ashuapmouchouan, County of Lake St. John, Que.

16563—May 20—Approving location of C.N.Q. Ry. station and baggage room at 16 Island Lake, Ct. Argenteuil, Que.

The Canadian Engineer

An Engineering Weekly

THE REVERSIBLE FALLS, ST. JOHN RIVER, ST. JOHN, N.B.

By ARTHUR V. WHITE, M.E. (Commission of Conservation, Ottawa.)

In the report *WATER POWERS OF CANADA*, recently published by the Commission of Conservation, there are mentioned a number of matters related to the conservation of our inland waters. Some of these matters are of special interest and would bear more extended discussion and investigation.

In the portion of this report which deals with the water powers of New Brunswick, Mr. Arthur V. White has drawn attention to the Reversible Falls at St. John, N.B. Having learned that additional data respecting these falls, or rapids, were available, we requested a memorandum of the physical facts so that they may be on record. The memorandum is as follows.—*EDITOR.*

The St. John River at its mouth in the city of St. John has a restricted area and an unusual rock formation in its bed. These features, coupled with the high tides, result in unique phenomena possessing latent water power possibilities.

(Photo by Arthur V. White).

Fig. 1.—The Reversing Falls, St. John, N.B.,

Showing condition of the water surface when tide is running out or in.

The bed of the river, at a place above the C.P.R. and Suspension bridges, known as the Pitch, has a ledge of rock from shore to shore. At the lower stages of the tide in the harbor, the river rushes over this ledge and creates turbulent and unnavigable rapids. During the higher stages of the tide the water level in the basin is so raised as, in part, to overcome the discharge of the St. John River. The incoming tidal waters are then in turn churned, opposed as they are by the ledge of rock just referred to. This cycle of changes takes place twice in the twenty-four hours. The condition of the river during the approaching high and low tide is represented in Figure 1. The river is navigable for large ships at the period of slack water. Figure 2 shows the calm condition of the water surface at slack water.

Thousands of horse power might be obtained if these rushing waters could only be harnessed. Such a project, however, appears impracticable. Schemes have been suggested for utilizing power from these Reversible Falls, and hopes expressed that some plan may yet be devised to take advantage of the power.

There are here presented three diagrams giving some physical data incident to the problem. Fig. 5 is a cross sectional view of the river at the bridges, and Fig. 4 a similar view at the ledges. The soundings in each figure are in feet below low water.

Figure 3 shows the typical regimen of the neap and spring tides at St. John harbor. With regard to elevations —taking the elevation of the bench mark at the customs house as 100.00—low water in St. John harbor is 44.40 and high water 71.40. Low water at Indiantown is 59.53, and high water 60.83.

No attempt should be made to alter the natural conditions which exist in such objects of nature as the Reversible Falls without the most mature consideration. Behind such phenomena there are often wise natural provisions which cannot safely be tampered with. Indeed, in the present instance of the Reversible Falls, it has been concluded by some persons,

(Photo by Arthur V. White).

Fig. 2.—Slack water at the Reversing Falls, St. John, N.B.

The river is only navigable for a short period at the time of slack water.

that the stirring of the waters by the ledge, contributes to the establishment of a temperature mean in the Bay of Fundy waters, which, in turn, assist to keep the harbor of

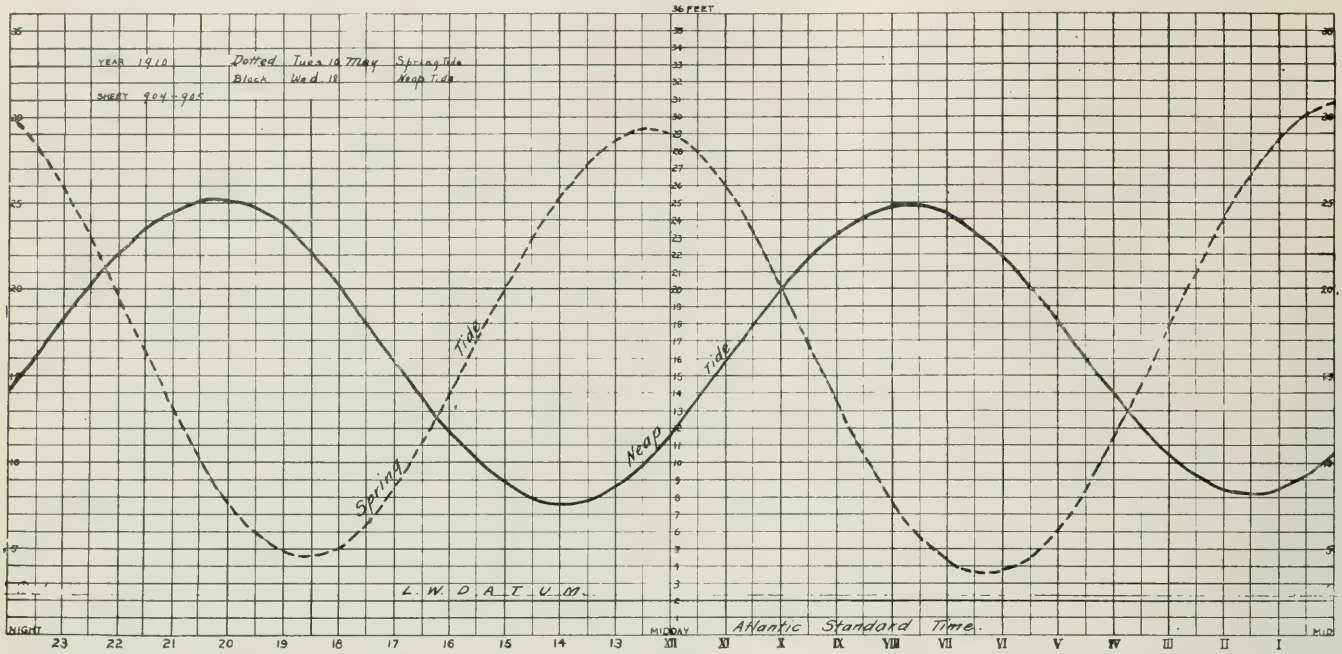

Fig. 3.—Curves showing typical rise and fall of spring and neap tides in the harbor at St. John, N.B.
(Courtesy of Tidal and Current Survey, Ottawa).

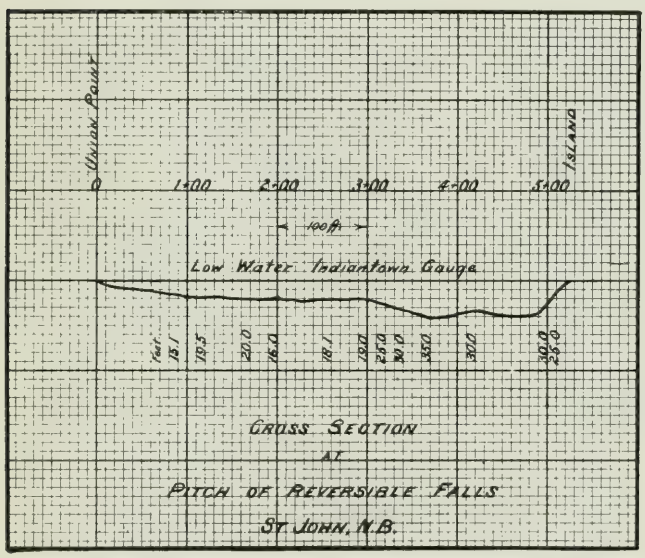

Fig. 4.—Cross section at pitch of Reversible Falls, St. John, N.B.

St. John free from ice, and in consequence assists to make it so valuable a winter port.

ALUMINIUM.

Aluminum, comparatively few years ago a rare metal, too expensive to have any particular economic value, has today come into wide use in a great number of industries. The consumption in the United States in 1911, according to the United States Geological Survey, was 46,125,000 lbs., the price in New York ranging from 18½ to 22 cents per lb.

The use of metal aluminium and its alloys in automobiles, dirigible balloons and aeroplanes is constantly increasing. In the form of magnalium it is used in the beams of analytical balances, and other new alloys are being constantly brought to public attention. The metal is also employed in paper decorations and for wrapping. It is reported to have been used in the textile industries, where it has been combined with silk, to which it imparts a peculiar brilliancy, particularly adapted to theatrical and ceremonial costumes. It has found and is constantly finding a host of applications in smaller articles of everyday use and ornamentation. The Ordnance Department of the United States Army recently awarded a contract for sixty thousand or more aluminium

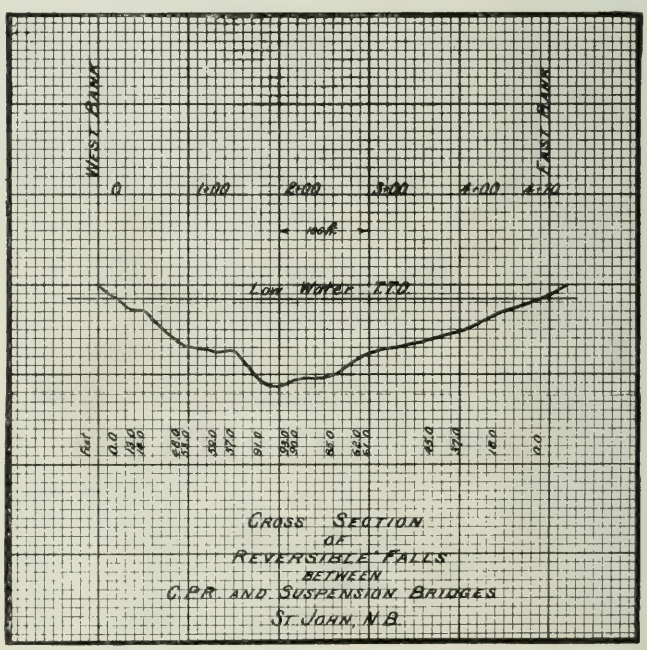

Fig. 5.—Cross section of Reversible Falls between C.P.R. and Suspension bridges, St. John, N.B.

canteens and cups. The metal is now being used in various other ways in the light field equipment of the army.

PUMPING BY COMPRESSED AIR.

In *The Canadian Engineer* of April 4th, 1912, we gave an abstract of a University of Wisconsin bulletin on the air lift pump. The use of compressed air for pumping purposes is becoming of such importance that a recent lecture by Mr. Herbert A. Abrams on this subject should prove interesting.

Mr. Abrams is connected as engineer with the Ingersoll-Rand Company and his lecture was delivered last year before the Department of Mechanical Engineering of Columbia University. It is published in the April, 1912, issue of the School of Mines Quarterly; we reproduce the lecture here almost in full.

The field in which compressed air can be used for lifting and forcing water is divided by Mr. Abrams into four distinct methods:

1. Pumps of the ordinary direct-acting type driven by compressed air;
2. Pneumatic displacement pumps;
3. The "return-air" system;
4. The "air-lift" system.

Direct Acting Pumps.—Mr. Abrams passes briefly over the use of air in place of steam for operating ordinary mechanical pumps. High economy must not be expected in a combination of this kind for the reason that pumps of this type, of themselves, are wasteful of power, and, generally speaking, no consideration is given as to whether they are to be run by steam or by air, no attention is paid to proper ratio of cylinders, and seldom is there any attempt to re-heat the air either before using it in a simplex or duplex pump, or between stages in a compound pump.

"Compressed air should be used in a great many instances where steam is now being wasted, but we are so inclined to listen to talk about 'compressed air efficiencies,' meaning always 'compressed air losses,' that we frequently lose sight of the more important final analysis, which is to define whether a saving in fuel is an actual credit or whether such apparent balance is not over-balanced in the item of extra labor or up-keep or general utility."

As compressed air is found driving steam pumps in mines, quarries, and wherever there is an available supply of air, Mr. Abrams briefly gives the simple rules used for proportioning pumps and the volume and pressure of air needed to run them.

The simplest way to find the quantity of free air and the pressure required is first to determine at what speed and under what air pressure the pump is to be run, and calculate the cubic feet displaced per minute at the pressure necessary to do the work. This may readily be converted into terms of free air at sea level or the greater quantity at any altitude. To this must be added a percentage, say 10 per cent., for the loss due to leakage.

With a given air pressure and head of water, the diameter of the air cylinder may be found by the rule: Determine the pounds pressure of resistance by taking one-half the elevation in feet, as representing the equivalent pressure in pounds, add one-third excess for pumps over 7-in. stroke. Divide this result by the pounds pressure of air at the pump, and the result will be the proper ratio.

Knowing the dimensions of the air cylinder and pressure, the free air requirements can be calculated by means of the simple formula,

$$V = 1.1 \frac{ASP}{144P_a}$$

where

V = volume of free air per cubic feet per minute,
S = piston speed of pump in feet per minute,
P = absolute air pressure at pump,
A = area of air cylinder,
P_a = atmospheric pressure at any elevation.

Problem.—Pump assumed over 7-in. stroke; head, 360 ft.; air pressure, 60 lb.

To find area of air cylinder, add one-third to the head (360 plus ⅓ = 480 ft.). Take one-half of this head as the equivalent pressure (240 lb.). Dividing 240 lb. by 60 lb. pressure gives a ratio of 4, or, in other words, the air cylinder should have four times the area of the water cylinder.

Having decided on a pump to handle 50 gal. of water per minute at a piston speed of 100 ft. as the proper size,

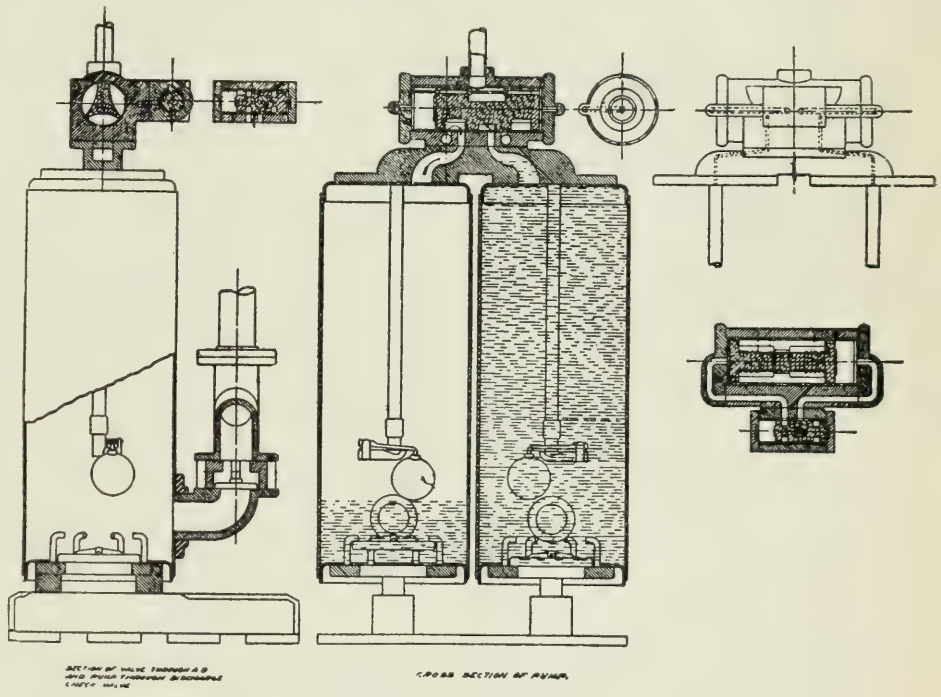

Fig. 1.—Compressed Air Displacement Pump.

we find, either by calculation or by manufacturers' tables, that the water end is represented by 3½ × 7-in. cylinder. Our ratio having been established at 4 to 1, the diameter of the air cylinder will be 7 in. and its area 38.5 sq. in.

Now, substituting in our formula the values so far obtained, we have,

$$V = 1.1 \frac{38.5 \times 100 \times 75}{144 \times 15} = 148 \text{ cu. ft. free air per minute,}$$

showing a total efficiency referred to I.H.P. in steam cylinder of compressor of approximately 19 per cent. If the air is re-heated to 300 deg., the requirement will be reduced about one-third.

Pneumatic Displacement Pumps.—Fig. 1 is a sectional view of a compressed air displacement pump. This pump uses air non-expansively, but owing to the fact that air comes in direct contact with the water pumped, without the intervention of moving parts, such as pistons or plungers,

the work under moderate heads, up to 100 ft., is done in a satisfactory and efficient way.

The pump consists of one or two cylinders with inlet and discharge valves for water, and a valve mechanism controlled by floats or other means for admitting compressed air directly to the surface of the water within the tanks, and for exhausting the air after the water has been expelled. The tanks must be submerged in a suitable sump or cistern properly protected, of sufficient depth to insure that the pump tanks will fill properly by gravity. It will be seen that the pump is really a simple apparatus. Water enters through the large inlet valves at the bottom. Air pressure entering at the top is alternately delivered to the chambers, expelling the water in them through the discharge valves and pipe. When a tank is nearly empty the contained air is exhausted through a port in the valve mechanism, while water replaces it through the foot valve as soon as the air pressure is relieved, the alternate discharge being entirely automatic.

The proper field of this device is that calling for the pumping of water at some distance from the source of power, where there is an unobstructed supply and a limited lift. Valves in the power house on the air line to the pump, or to as many of them as may be needed to pump from a number of sources, control the operation, and pumping must continue as long as air is supplied.

The advantages are that these pumps can be easily installed, and where an existing supply of compressed air is available the cost of equipment is low. There is no pump house to build and maintain at the water supply; the operation is controlled in the engine room; there are no piston or plungers to repair and renew, and the wear on valves is less than in any ordinary direct-acting mechanical pump. Neither lubrication nor packing is required and the attention charges are reduced to a minimum. Its working is not affected by muddy or gritty water.

These facts adapt the pump for dye works, bleacheries, pulp mills, and for handling solutions. It may be used to take water from a cistern or reservoir filled by the air-lift from wells, or placed in a remote sump in a mine or quarry, it can be employed to deliver water to the main pumps.

Since the pump operates by the direct displacement of a volume of liquid by a volume of air under suitable pressure, it follows that simple rules can be given for arriving at the volume of air and pressure needed to do the work.

Reduce the quantity of water in gallons per minute to cubic feet. Multiply the total head (static head plus water-pipe friction) by 0.434; this gives the working air pressure at the pump. Next find the ratio of air pressure to atmosphere, which multiplied by the cubic feet of water per minute gives the cubic feet of free air per minute needed at the pump to displace this volume of water.

Knowing the volume of free air required, 5 to 10 per cent. should be added for leakage and clearance according to the special conditions.

This is net, actual free air and not piston displacement of compressor; therefore, in figuring on a compressor to do the work, volumetric efficiency must be taken into consideration, following the general practice in such cases, according to the pressure, size and type.

Problem.—Source of supply, a river; distance from power house, 1,000 ft.; lift, 60 ft.; diameter discharge main, 4 in.; quantity of water required per minute, 150 gal.

150 gal. = 150 ÷ 7.5 = 20 cu. ft.

Static head ..... 60 ft.
Friction head 150 gal. per minute in 4-in. pipe 1,000 ft. long ..... 16 ft.

Total head ..... 76 ft.

$$76 \times 0.434 = 33 \text{ lb.}$$

$$\text{Ratio } r = \frac{33 + 15}{15} = 3.2$$

Free air = 20 × 3.2 = 64 cu. ft. per minute.

Allow 10 per cent. for leakage and clearance = 70 cu. ft. net.

If the compressor selected will show a volumetric efficiency of 80 per cent., the piston displacement required will be 70 ÷ .080 = 88 cu. ft. per minute.

$$\text{Theoretical horsepower} = \frac{150 \times 8.33 \times 76}{33{,}000} = 2.88.$$

I.H.P. in steam cylinder of compressor = 8.5.

Total efficiency = 2.88 ÷ 8.5 = 33 per cent.

Return Air System.—The elevation or transfer of water and other fluids or semi-fluids by direct displacement with compressed air is so natural and self-evident a proposition as to need almost no suggesting. It appeals at once merely on the ground of convenience and simplicity. But the principle as ordinarily applied has been open to the objection that it was not economical.

One characteristic of the ordinary, plain, displacement pump is waste of power entailed by direct release of the displacing air after the fluid is ejected from the pump tank. This air, after doing its work, is still at practically full pressure, therefore having all its potential energy of expansion. Its direct exhaust into atmosphere after displacement is the throwing away of this expansive power without any useful effect.

If air pipes are carried back from the pump to the compressor so as to add the residual pressure after displacement to the reverse side of the compressor piston, where it will help in compressing air into the pump tank, we have a return-air, expansive displacement pump, operating at good economy.

Mr. Abrams emphasizes, at this point, the fact that both the plain displacement pump and the "return air" system have the following advantages which are unique in that, while other pumping systems have some of them, no other systems combine them all to such remarkable degree:

1. Simple in construction, installation and management.
2. Wholly automatic in operation.
3. Under instant and complete control from the compressor room, however distant.
4. No delicate mechanism exposed to corrosive or abrasive action.
5. No oil or other lubricant required by the pump.
6. Not affected by any excess submergence except that operation is improved under a hydraulic head.
7. Applicable to the pumping of all fluids or semi-fluids, as well as mud, sand, or any debris which will pass the valves.

Where water is to be pumped, the field of the pneumatic displacement pump and the return-air system is that in which large volumes are to be handled from a generous source of supply, where complete submergence can be secured, such as in a river, lake, mine or quarry sump, large spring or an excavated well. This, at once, opens to them the supplying of water for small municipalities, shops, mills, factories, etc.

The fact that these systems will handle anything sufficiently fluid to pass their valves adapts them also to the handling of solutions in salt works and bleacheries; the moving of semi-fluids, as in pulp mills; the handling of cement, slurry and marl; the pumping of glass sand for glass factories; elevating salt solutions in salt works, and the pumping of sewage.

Under normal conditions it is safe to say that the return-air system will show an average efficiency of 50 to 55 per cent., this efficiency being the ratio of horse-power of water lifted to the indicated horse-power in the steam cylinder of the air compressor, including all losses. It is easy to estimate from these figures just what they mean in terms of fuel saving.

Yet the question of fuel economy is but one argument in favor of the return-air system. Another argument is that the compressed air system may be operated with a far less boiler horse-power, with a corresponding reduction in first cost of boiler plant, interest, maintenance, repairs and firing cost. Where a plant is crippled by a shortage of boilers, the substitution of the return-air system for a less economical pumping system will relieve the embarrassment.

Continuing still further the argument for this system, Mr. Abrams notes that the tank equipment needs absolutely no care. The operation being entirely under control from the engine room, the engineer can at any time start, stop or vary the pumping. There is no possibility of drowning out the system. In fact, it operates with proportionately less power as the height or head of water above the tanks increases. It cannot become choked by such silt or dirt as may enter a mine sump.

The return-air system cannot be classed as a pump, or as machinery of the kind regularly catalogued and listed. It is a complete system in itself, consisting of an air compressor, a receiver, a reversing switch, two air lines, each leading from the compressor through the switch to one pump tank, and two pump tanks, all in a closed circuit, in which, by a regular cycle of operations, one air volume is compressed, expanded, recompressed and re-expanded, corresponding with a discharge of one of the pump tanks.

The principle of operation is simple. Compressed air is admitted to a tank filled with water, or any fluid, forcing the fluid out through a check valve and pipe line, and at the same time the compressor is drawing air from the other tank, the charge of air being regulated so that when a tank is empty, the other is full, at which time the switch reverses, thereby reversing the action of the tanks.

The cycle of operation will be better understood by referring to Fig. 2; A and B are twin displacement tanks, preferably completely submerged, though they operate if so placed as to be filled by siphon action. A^1 and B^1 are the two air pipe lines. C^1 and C^2 are discharge check valves preventing the return of the fluid ejected.

D^1 and D^2 are check valves preventing the discharge of the fluid through the inlet. E is the discharge pipe from both tanks.

F is the automatic switch controlling the pumping cycle. G^1 and G_2 are the tank risers.

H is the compressing cylinder of an air compressor. J is the automatic compensating valve which keeps the system supplied with air.

In the diagram as shown, air is being withdrawn by the compressor H from the tank B and is being compressed in tank A. At the same time the fluid is entering the tank B through check valve D^2, while it is being forced from the tank A through the riser G^1, the check valve C^1 and the discharge pipe E.

The mathematical analysis of the system is difficult. Any one interested in a full discussion of the problem will find it fully brought uot by Prof. Elmo G. Harris in Vol. 54 of the Transactions of the American Society of Civil Engineers.

In order to proportion a plant correctly, the needed data are as follows:

Qw = the quantity of water to be pumped in cubic feet per second.

h = the total lift, or head, in feet.

l = the total length of air pipes, the distance from compressor to pump tanks.

Having these, we must compute:

Q_a = the volumetric capacity of the compressor, or the piston displacement in cubic feet per second.

V = the volume of each pump tank (cubic feet).

d = the diameter of air pipe (in inches).

D = the diameter of water pipe (in inches).

H.P. = the maximum horse-power required of the steam end of compressor.

From the formula:

$$Q_a = Qw\ [1 + 1.4 \log_e R]$$

the following Table I. has been prepared, showing the size of compressor, pipes, etc., required for various heads, based on 100 gal. of water per minute; for other quantities, the dimensions will be directly proportional. The table assumes the pump tanks to be fully submerged.

Table I.—Dimensions for Return-Air System.

Lift in feet.	Capacity of compressor in cubic feet per minute piston displacement for 100 gals. per minute.	Max. I. H. P. of air cylinder.	Max. I. H. P. of steam cylinder.	Average H. P. of steam cylinder.	Area of air pipe in sq. in. for each 100 gal. capacity of plant.	Area of water pipe in sq. in. for each 100 gal. capacity of plant.

Air-Lift System.—The air-lift system of pumping, measured on the power basis, is not an efficient method of raising water, but where it is and can be applied, it fills a certain field and in that class of work does service that no other pump can do, and does it in a most satisfactory way. This method of pumping has been most generally applied to raising water from artesian wells. There are not many underground formations in which wells can be located close together without affecting each other when pumping, and for that reason it is best to spread them out on a line of what we call the line of underground flow. Some formations are so tight that wells have but little capacity, and in such formations it is particularly necessary that the wells should be scattered and pumped moderately. For the reason that separate pumping units entail high first cost and labor for

attendance, the air-lift system is recommended. An economical central pumping station will serve any number of wells, compressed air being capable of transmission in proper sized pipes for great distances without serious loss.

The required equipment consists of an air compressor located at some convenient point, preferably in some existing power station where it can take advantage of economical steam conditions, an air receiver, and a pipe line leading from the receiver to the well or wells. The pump proper consists of nothing more than two plain pipes, one for air

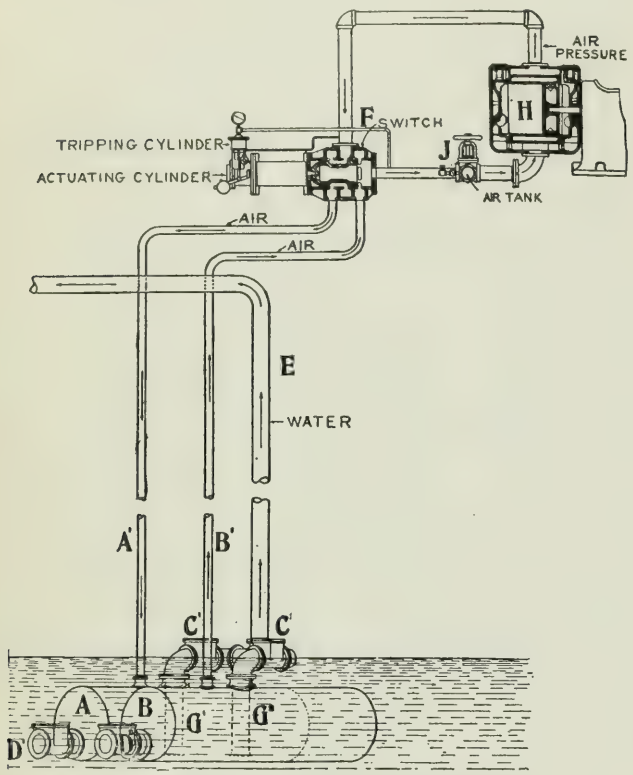

Fig. 2.—Return-Air Displacement System.

and one for water; these pipes run down inside of the well and are submerged for a certain depth proportionate to the lift when the pump is at work. Fig 3 shows the different methods of piping wells. All wells are not alike, therefore it is a special problem in every case to determine the size and arrangement best suited.

Each method here shown has its use, depending upon the diameter and depth of the well, whether the well is cased or not, the lift, volume of water to be pumped, and character of the water-bearing strata. The arrangement most generally used, where conditions permit, is shown in No. 1, Fig. 3. This is the Pohle or "side-inlet" method, in which the discharge and air pipes are placed side by side in the well, joined by a suitable foot-piece.

In No. 2, Fig. 3, compressed air fills the annular space surrounding the up-take pipe and is free to enter the rising column at all points of its periphery, at the same time acting without obstructing or contracting the discharge pipe anywhere

Fig. 4 shows the tubular foot-piece. This device aims to provide a means for actually dividing air into fine streams, which we have found to be the best condition in which air can be introduced into the rising main. Air from the supply pipe fills the hollow base of the foot-piece. The base-plate is studded with ¼-in. wrought-iron pipes about 18 in. long extending upwards to a point where the water passes from the foot-piece into the discharge pipe, at which juncture the bubbles of air are released. Ample space is provided for the inflow of water to the foot-piece through the bottom openings, augmented by the larger side inlets shown. Thus we have in the foot-piece designed for a 5-in. discharge pipe a subdivision of air into thirteen ¼-in. streams, with the added advantage that these separate small pipes will tend to act as governors to control the discharge of the air.

The usual capacities allowed for the side-inlet method are as follows:

Air Pipe Connection.	Water Pipe.	Size Well.	Maximum Economical Capacity on Moderate lift. Gals. per min.
½ in.	1 in.	3 in.	7
¾ "	1½ "	4 "	20
1 "	2 "	4½ "	35
1 "	2½ "	5 "	60
1¼ "	3 "	6 "	100
1½ "	3½ "	7 "	140
1½ "	4 "	8 "	190
1½ "	5 "	9 "	250
2 "	6 "	10 "	350

No. 3, Fig. 3, shows the Sounders system. A central discharge pipe is suspended in the well, the air passing down between it and the well casing. If the well is not cased a second pipe must be used outside of the main discharge pipe, the air, as before, filling the annular space between the two pipes. In estimating pipes under this system it is usual to allow capacities as follows:

Lift, 25 ft., 15 to 20 gal. per minute per square inch area water pipe.

Lift, 50 to 125 ft., 12 to 15 gal. per minute per square inch area water pipe.

No. 4, Fig. 3, is the so-called "central air pipe" system. This method is generally used where the lift is low, and to obtain the greatest possible output from what are termed "strong wells," i.e., wells having a strong static pressure and finding their supply in gravel or open rock formations. The air pipe is suspended in the well without the usual discharge pipe. The proper sized air pipe for different sizes of casing and capacities are about as follows, depending upon the lift and submergence:

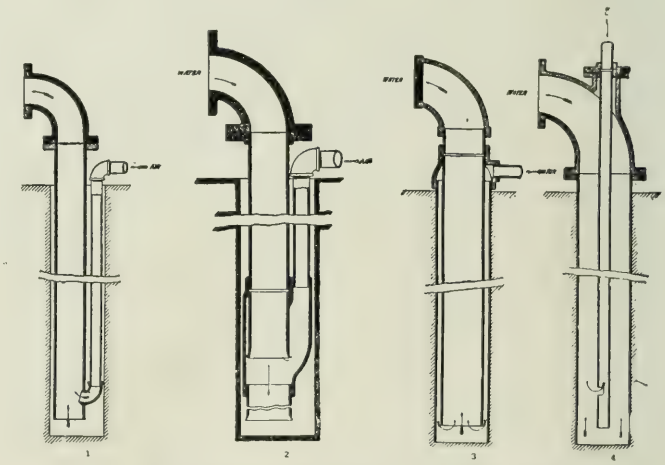

Fig. 3.—Different Methods of Piping Wells.

Size of Casing.	Size of Air Pipe.	Capacity. Gal. per min.
3½ in.	1¼ in.	80 to 100
4 "	1½ "	100 to 150
5 "	2 "	150 to 250
6 "	2 "	275 to 375
8 "	2½ "	500 to 665
10 "	2½ "	775 to 1000

Notwithstanding the fact that the air-life system has been in commercial use for nearly 20 years and thousands of plants are in daily operation all over the world, no mathematically correct formulas have been published covering the design of these pumps, nor is there exact information at hand for calculating the volume of air and pressure required to operate them under all conditions. This is due to a number of variable factors which enter into each proposition, and if we are to undertake to derive a practical working formula we must assume certain efficiencies for the system, and assume also that the wells will be properly piped to meet the proper relation of submergence to lift.

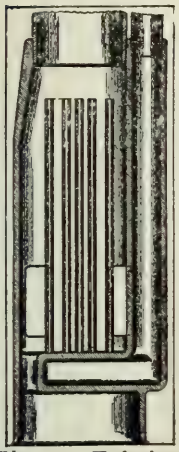

Fig. 4.—Tubular Foot Piece.

Although impossible to construct a formula which can be applied uniformly to all conditions met in this class of work, yet, as Mr. Abrams points out, we can define the trend and introduce certain rules which will permit any engineer to calculate the requirements for any given proposition when **the exact** data covering the case are known. The data required and the factors entering into these calculations may be reduced to the following:

V_a = free air piston displacement required to raise 1 gal. water.

h = total vertical lift in feet.

H = submergence in feet.

C = constant (efficiency of the system).

Before proceeding, the symbols above written must be clearly understood.

V_a is the free air (piston displacement of the compressor) required to raise 1 gal. of water, due allowance having been made for the ordinary volumetric efficiency of the air compressor. If the compressors are in bad shape or poorly designed, of course, more displacement will be required from such a machine than from a well-designed compressor in good working order.

By "lift" is meant the total vertical lift from the pumping level of the water in the well to point of discharge.

"Submergence" is the depth the air pipe is submerged below the pumping level of the water in the well, and is an important factor in any installation; the percentage of submergence, so often heard of, is the percentage of the total length of pipe which is submerged in the solid water when pumping. The necessary percentage of submergence varies in accordance with the lift; low lifts require proportionally more submergence than high lifts; or, in other words, the necessary submergence decreases as the lift increases. The range of these percentages lies within the following limits: For lift of 20 ft., 66 per cent.; for lift of 500 ft., 41 per cent. The average best percentage in the class of work usually encountered will lie between 50 and 65 per cent. Submergence also governs the pressure required, both the starting pressure and the working pressure. The air-lift differs from other pumps in that the pressure necessary to raise the column of water does not depend upon the head, h, but upon the submergence, H, or, in other words, H is the actual head against which the air pressure acts.

The first step in a calculation of this kind is to determine from the lift what the proper submergence should be, and knowing this submergence, the work can be easily calculated on the basis, $P = 0.44\ H$.

We are now ready to calculate the air volume required (free-air piston displacement) to raise 1 gal. of water. The following formula may be used, which closely approximates average practice (in part suggested by Mr. Edward A. Rix):

$$V_a = \frac{h}{C \log \frac{H + 34}{34}}$$

The annexed table also shows the value of C calculated from the efficiency of the system under various heads, with proper submergence.

Table for Value of C.

h = Lift.	C = Constant.
10 ft. to. 60 ft.	245
61 ft. to 200 ft.	233
201 ft. to 500 ft.	216
501 ft. to 650 ft.	185
651 ft. to 750 ft.	156

Problem.—Given a bore-hole, well, or shaft 250 ft. deep, the water in which stands 50 ft. below the ground surface, but which falls 25 ft. when being pumped at the rate of 200 gal. per minute, and it is required to raise the water 25 ft. above the ground:

Standing water level in well, measured from surface.. 50 ft.
Drop when pumped ..... 25 ft.
Elevation above surface to raise water..... 25 ft.

Total lift .....100 ft.

If the best ratio of submergence for a lift of 10 ft. is 58 per cent., then

$$H = \frac{h \times 0.58}{100-58} \text{ or } \frac{100 \times 0.58}{100-58} = 138 \text{ ft.}$$

and applying our formula,

$$V_a = \frac{100}{C \log \frac{138 + 34}{34}}$$

and further introducing the value of C from the table, we have

$$V_a = \frac{100}{233 \times 0.704151.} = 0.60.$$

V_a = 0.60 cu. ft. (piston displacement) per gallon of water; hence for 200 gal. 200 × 0.60 = 120 cu. ft. will be required.

The next calculation is to find the starting and the working pressure. Observe that the normal or standing water level is 25 ft. higher than the working, which indicates a submergence at the beginning of operations equivalent to 138 + 25 = 163 ft. The starting pressure must be just sufficient to overcome that due to the height of the water column above the footpiece.

163 × 0.44 = 72 lb. gauge, the starting pressure.

0.44 H = 138 × 0.44 = 61 lb., the working pressure.

The actual pumping level in a well or group of wells can seldom be known in advance to a test. It is customary to assume certain conditions of lift and submergence, basing such conclusions on experience, and proceed to pipe the wells accordingly. After the piping is installed and the working conditions arrived at, the submergence is altered to suit by raising or lowering the pipe in the well until the best ratio is established.

The quantity of water a well will yield depends upon its diameter and the natural flow. It is also essential that the pipes both for air and water be properly proportioned, for the reason that velocity of flow is an important factor; if too large a pipe is used the air gets through without doing all the work it should, and, on the other hand, if the velocity is too high there is undue friction loss and also inefficient expansion of the air bubbles. The best results are ordin-

arily obtained by providing for a discharge of 12 to 15 gal. per square inch area of discharge pipe.

Tables are available for determining the friction loss of air pipes. It is, of course, essential to keep this loss within reasonable limits. The flow should not exceed 1,500 ft. per minute.

One reason why the air-lift has been so popular, aside from its flexibility and simplicity, is the fact that the yield of a well is frequently increased by its use. Wells can be cleaned of sand, keeping open the water-bearing seams. As there is little apparatus in the well, an unobstructed flow is assured. The air-lift will handle all the water a well yields, but if a given well is equal, at its maximum, to a flow of 50 gal. per minute the air-lift has so miraculous power whereby the yield can be increased.

Water is also purified and improved by the intimate commingling with air on its passage through the discharge pipe. There is a complete aeration as the water flows upward, putting it in condition to throw off sulphur gas, precipitated iron, and in a measure prevent vegetable growth.

Special Uses for the Air-Lift.—The pumping of oil wells offers a superior opportunity for the air-lift, and in this line of work compressed air has been pre-eminently satisfactory. One of the advantages possessed by the air-lift, whether it be in pumping water or oil, is the ability of the system to handle sand and gritty matter.

On account of the facility with which the air-lift, owing to the fact that no working parts come in contact with material being pumped, can handle sand, mud, and other substances destructive to ordinary mechanical pumps, it is an ideal method for pumping in the following cases:

1. Slimes, a mixture of water and the very fine portions of crushed ore coming from a reduction plant.

2. Sand and water for stone saws. All preparation necessary for work of this kind is a "master" well or pit sunk to a proper depth to provide the necessary submergence.

3. The air-lift has done excellent work as a dredge pump and if its usefulness along these lines were better appreciated we should see a great many more installations. The arrangement of air-lift units on a scow, with proper facilities for raising and lowering the pipes, presents unexcelled features of simplicity and capacity.

4. Agitation of slimes in the cyanide process also offers an opportunity for the air-lift, as complete and satisfactory aeration can be brought about by placing an air-lift in a cyanide tank specially designed for the purpose.

The air-lift is past the experimental stage and is taking its place with other applications of compressed air where steady, reliable results are appreciated.

TESTS ON REINFORCED COLUMNS.

The results of an extensive series of tests of the strength and elastic properties of concrete columns reinforced with spirals and longitudinal rods, conducted by Prof. M. O. Withey, assistant professor of mechanics in the university laboratory for testing materials, are contained in Bulletin 466, University of Wisconsin, Engineering Series, Vol. 7, No. 1, just issued. The tests were made from a rather comprehensive point of view, no less than seven elements being thoroughly investigated; to do this, sixty-six columns of commercial size were tested. The findings, which in most cases are noteworthy, briefly comprise the following:

1. With respect to varying the richness of the mixture, the fact was developed that rich mixtures are more economical than lean ones, provided materials can be obtained at average prices. It was found that more economical mixtures are produced when the proportion of cement to aggregate, by weight, lies between 0.2 and 0.7.

2. With reference to the effect of varying the percentage of spiral reinforcement, the tests showed that although the yield point is practically independent of the spiral reinforcement, the ultimate strength and toughness are directly affected by it; one per cent. of closely-spaced spiral of high carbon steel was shown to be sufficient for lateral reinforcement.

3. As to varying the percentage of longitudinal reinforcement, it developed that the addition of longitudinal steel can be made to considerably increase the yield point, ultimate strength and stiffness. As, however, cement is ordinarily a more economical reinforcement than steel, it does not seem advantageous to use in combination with a rich concrete, more than two or three per cent. of longitudinal steel.

4. In regard to the effect of repeated or time loadings, no definite conclusion was reached, although the results plainly indicate that there is practically no increase in set or deformation after a few repetitions of loads equal to 40 to 50 per cent. of the yield point.

5. With respect to columns eccentrically loaded, the close agreement between the values derived from the tests and the theoretical values shows that common formula

$$S = \frac{P}{A} = \frac{Mc}{I}$$

for short homogeneous columns eccentrically loaded, is applicable to reinforced concrete columns.

6. As to the effect of differences in end conditions, that is, the bearing surfaces, the tests disclose that the strength of a column will be about as great when resting on a footing as when bedded on a metal plate, provided the base is properly reinforced.

7. With reference to the relative value of plain and deformed bars for longitudinal reinforcement, the results with the use of corrugated bars of high carbon steel were so uniform and the strengths so high that this type deserves much consideration. The use of deformed bars of high elastic limit was shown to be more economical, with certain ratios of unit prices, than plain round bars of mild steel.

The bulletin contains a very complete bibliography of published matter on the subject of testing reinforced concrete columns.

AN INTERESTING JUDGMENT.

A legal judgment that has a particular interest to contractors and engineers has been handed down in the Court of Review recently in Montreal, Que. The case arose over the collapse of a tank. The lower court had condemned the defendants to pay $9,590.68 damages on the grounds that the collapse of the tank on the building was due to the weakness and insufficiency of the walls, and that it was incumbent upon the defendants, as contractors, to assure themselves of this condition, before attempting to erect the superstructure and tank. The Court of Review whilst maintaining the damage award, holds that the collapse was due to a defect in the construction of the steel work supporting the tank. For this the defendants were also responsible by reason of the fact that they had undertaken to carry out the work on the understanding that they would look after all details connected with such work.

THE DIGESTION OF SEWAGE SLUDGE.

By Charles Saville.*

There are, as is now well appreciated, many advantages in providing for the rapid and complete digestion of sewage sludge. In this connection "digestion" refers to the thorough decomposition, or rotting out, of non-resistant organic matters which are easily putrescible and thereby capable of creating a nuisance.

The quantity of sludge deposited from sewage is large. In a fresh condition, and containing 90 per cent. or more of water, it sometimes amounts to as much as 750 cu. ft. per month per thousand persons connected with the sewers, this being the figure reported from Elberfeldt, Germany, where the sewers are built on the separate system. Furthermore, fresh sludge usually has an objectionable odor which may continue to be noticeable for a long period. Because of these two characteristics, the disposal of fresh sewage sludge, particularly in the vicinity of thickly settled communities, is a difficult problem.

With well-digested sludge, on the other hand, the volume to be handled is comparatively small, being, under certain conditions, less than one-fifth as great as with fresh sludge. This great difference is due to the smaller water content of the digested sludge and to the breaking down, or rotting out of the easily putrescible organic matter, part of which passes off in the form of gases. The extent to which fresh sludge is reduced in volume by digestion depends on numerous factors, including the nature of the organic matter in the sludge, the amount of mineral matter present, the condition under which the digestion takes place, the length of the digestion period, etc., etc.

It is also true that well-digested sludge has no objectionable odor, because the easily putrescible organic matter in it has been thoroughly rotted out. Under certain conditions digested sludge flows easily. Furthermore, on account of the entrained gases of decomposition it dries quickly to a porous, earthy mass which can be readily handled and easily disposed of.

It is thus evident that there is much to be gained from a complete digestion of sewage sludge, and throughout the past 40 years considerable time and thought has been spent in attempts to find the most efficient means of bringing about the desired results.

Perhaps the best known method of effecting the digestion of sewage sludge is the "septic tank," in which the deposited sludge is allowed to digest in contact with the flowing sewage. Under these conditions the rate of digestion is not usually high, and as the digestion of the sludge makes the sewage itself septic and malodorous, and at the same time interferes with the settling action, the ordinary septic tank is gradually going out of favor.

The next step in advance was taken at the State Experiment Station in Lawrence, Mass., by removing the deposited sludge from the settling tank to a separate digestion tank. This method of sludge treatment was first tried some 12 or 13 years ago, and has since been adopted on a practical scale in England as well as at a few places on the Continent; but only to a small extent in this country. In some instances it has proved comparatively successful, and the method has recently been adopted by the city of Baltimore, Md.

At many places, however, the results have not been entirely satisfactory; in Germany, for example, as reported by Prof. Thumm in his recently published book on sewage disposal.* Similar unsatisfactory results have also been reported from the sewage testing stations at Philadelphia and Chicago. It is not strange, therefore, that the past 10 years have witnessed the search for a still better means of bringing about the desired digestion.

This has gradually resulted in developing, first in England and then in Germany, a tank with two chambers; one, through which the sewage flows and in which the suspended matters settle out; the other, for the storage and digestion of the sludge, being so arranged that not only the sludge, but also the products of digestion, cannot have an injurious effect on the sewage in the settling chamber. In this type of tank, in the form in which it has been developed in Germany, there is no flow of sewage into or through the sludge chamber. Consequently the soluble organic matters in the sewage standing in the sludge chamber soon become completely decomposed, after which the digestion of the sludge takes place in a liquid which is practically free from easily putrescible organic matter.

Such tanks are spoken of as the Emscher or Imhoff tank. They have been operating on a practical scale in Germany for six years and have given uniformly good results. In this country there are as yet only a few in operation; but wherever such tanks have been given a thorough test on a small scale with ordinary city sewage, the digestion of the sludge has been excellent, and a large number of municipalities throughout the country are now planning to use them.

The time thus seems appropriate for inquiring into the relative advantages of the separate sludge digestion tanks and the Imhoff tanks.

In discussing this question the writer would suggest the advisability of keeping in mind the following points of view:—

First.—Can separate sludge digestion tanks be made to give as good results as Imhoff tanks; with respect not only to the character and quantity of the digested sludge; but also to the effect on the settled sewage and subsequent process of purification, and to the production of objectionable odors, both during the settling of the sewage and during the digestion and subsequent disposal of the sludge

Second.—Will the digestion of the sludge be as rapid in separate sludge digestion tanks as in Imhoff tanks, and will the cost of construction and operation be as low?

Sludge which has been thoroughly digested in separate tanks probably does not differ materially as to character or quantity from that which has undergone digestion in ordinary septic tanks or in Imhoff tanks; but with the type of separate digestion tanks thus far used, the removal of the sludge from the tanks has not proved as easy as with Imhoff tanks, and in some instances it has been found difficult (with separate digestion tanks) to bring about a satisfactory digestion of the sludge.

Small scale tests with a separate sludge digestion tank at the Philadelphia Sewage Testing Station gave disappointing results, as may be seen by reference to page 171 of the report, where the opinion is expressed that "the placing of sludge in open water-tight tanks is not an advantageous means of disposal." In these tests fresh sludge was added to the digestion tank every two weeks, and although there was some gas formation and liquefication during the first part of the test, this ceased altogether with cold weather, which may be explained in part by the fact that the tank was quite shallow. It is said that the tank always had a thick scum and that there was no material change in the character of the underlying sludge.

---

* Of Hering & Gregory, Consulting Engineers, New York.

* Handbuch der Hygiene, II. Band, 2. Abteilung, Wasser und Abwasser.

The excess liquid which overflows from separate digestion tanks will be of a peculiarly objectionable character and must be purified. If discharged back into the settling tank it would tend to make the sewage septic, and in any case presents a difficult problem for solution.

The sludge as discharged into separate digestion tanks will always contain some sewage having undecomposed organic matter in solution, so that the process of digestion is likely to be somewhat similar to that occurring in ordinary septic tanks, with consequent probability of the production of objectionable odors. These odors, as pointed out by Mr. Pearse, are likely to be especially noticeable at times when the sludge is being discharged into the digestion tanks, for the reason that the sludge, having already begun to decompose, contains foul-smelling gases which, due to the stirring up of the sludge, will escape. The separate sludge digestion tank at the Chicago Testing Station is said to have produced a very noticeable putrid smell, and engineers who have inspected, during warm weather, the operation of the separate sludge digestion tanks at Forest Park, Baltimore, report somewhat similar conditions.

Another point of importance in this connection is that such separate digestion tanks as have been built have a larger surface of liquid exposed to the atmosphere than is the case with Imhoff tanks, and may thereby give a greater opportunity for objectionable odors to become noticeable.

In Birmingham, England, where sludge from septic tanks was deposited to a depth of 5 or 6 ft. in large open lagoons, Mr. Watson stated that a thick, strong crust was formed on the surface, beneath which the sludge remained in its original condition, with no apparent loss in amount, and continued to give off foul odors irrespective of the age or density of the deposits. It would no doubt be possible to mention other instances in which separate tanks have not been successful in bringing about a satisfactory digestion of the sludge. It should be stated here, however, that experiments now being made in Birmingham under Mr. Watson's direction indicate that separate sludge digestion tanks, when operating with Birmingham sludge under certain conditions, can be made to give a well-digested sludge.

The effect of this method of sludge treatment on the flowing sewage is likewise a matter of considerable importance. If the sludge is removed from the settling tank under water this must be done at frequent intervals (say a week or sometimes even less in warm weather), in order to prevent a partial decomposition of the organic matter in the sludge previous to its removal from the settling tank. Such partial decomposition in the settling tank, by stirring up the deposits, interferes with the settling action and has the effect of making the sewage septic. This may lead to the production of objectionable odors around the settling tank. Unless the sewage, as well as the sludge, is removed at intervals from the settling tank and the entire tank thoroughly cleaned, there is pretty sure to be trouble of the above-mentioned variety, as it is difficult, even with specially designed tanks, to remove from the settling tank under water all of the sludge.

The second point of importance to keep in mind is whether the digestion of the sludge can be effected as quickly in separate tanks as in Imhoff tanks. If the digestion is slower the tanks must be larger, which, with this method of treatment, is an important factor to be considered, as it is necessary to have two distinct sets of tanks.

The digestion of sewage sludge is a biological process and without doubt proceeds rapidly only when the environment has been made suitable for the particular kind of bacteria which do the work, and when other unnecessary types of bacteria are so far as possible excluded. The creation of the proper environment requires time, and after the environment has once been created it is desirable, just as with a sprinkling filter, to have the food supply, in this instance consisting of sludge particles, enter the tank in a continuous stream and at a uniform rate. This is not easy to arrange with separate sludge digestion tanks. Consequently every time a new supply of sludge is added to the tank "the balance" of the bacterial activities is upset, partly because the newly added sludge, including some sewage and numerous varieties of bacteria, constitutes such a large proportion of the total contents of the tank.

In many of the separate digestion tanks thus far operated no provision has been made for having, above the sludge deposits, a considerable depth and volume of water in which the sludge can be kept, by the rising gases, in a more or less continuous state of motion. The bacterial toxins can, therefore, not escape easily nor are fresh sludge surfaces exposed to bacterial action as frequently as desirable, all of which tends to check the rapidity of digestion.

To sum up, it seems probable that although separate sludge digestion tanks can be made to give sludge of a satisfactory quality, the time required for complete digestion is nevertheless likely to be longer than with tanks of the Imhoff type, thus calling for larger tanks. There is also a greater possibility of the production of objectionable odors.

The cost of operating separate sludge digestion tanks is in most instances likely to be higher than with the type of tank which includes both a settling chamber and a sludge digestion chamber. In the first place, as already pointed out, the best results with respect to the effect on the sewage itself can be obtained only when the settling tank is completely emptied and cleaned at regular intervals. Secondly, it is questionable whether fresh sludge can be removed as easily under water as completely digested sludge. Furthermore, the removal of sludge from one tank to another always involves loss of head and in many instances may necessitate pumping. Finally, the removal of sludge from some separate sludge digestion tanks, even after more or less complete digestion, has been found to be a slow and expensive process.

At the small disposal works in Forest Park, Baltimore, for example, the writer saw four men at work shoveling the digested sludge out of the tank. In cases where this method of removal has to be adopted the construction of an extra tank may be necessary, since one tank will be out of commission much of the time. The necessity for purifying the liquid which overflows from the separate digestion tanks has already been stated in detail.

Although separate sludge digestion tanks have certain disadvantages, their adoption under some conditions may prove desirable. In such cases it would be advantageous to make the tanks as deep as possible, so that the digested sludge when removed will have a comparatively low water content and contain a part of the gases of decomposition. When first placed in operation it would be desirable to fill the tanks with clean water, which contains no easily decomposable organic matter. This procedure will tend to lessen the production of odors, particularly during the "ripening time." The fresh sludge should be discharged into the tank at regular intervals and in comparatively small quantities, so that the amount of sewage accompanying the sludge will be small in comparison with the whole body of liquid in the tank, and will, therefore, not tend to make this liquid odorous.

The tanks ought never to be completely emptied, as it will then be necessary for them to pass once more through the ripening time. If the gas developed does not prove sufficient to keep the sludge well stirred up so that new surfaces are constantly being exposed to the action of the bacteria, it may be possible to add certain cellulose sub-

stances which will increase the gas formation, or to stir the sludge artificially, with a paddle, with compressed air, or with clean water. In case water is used for this purpose there would be an overflow from the tank which would probably require purification.

It is to be hoped that those who have had experience with, or knowledge of, the operation of separate sludge digestion tanks will contribute to a discussion of their relative advantages or disadvantages so that, before forming definite opinions, engineers may have the benefit of as many as possible of the available data.

THE DIESEL OIL ENGINE.

Since its commercial introduction in 1897 this engine has steadily worked its way into the foremost ranks of motive power producers and is to-day considered to be the most perfect piece of mechanical construction for transforming the heat energy in oil fuel into mechanical energy; the thermal energy being about 48% with an effective or brake energy of 35%.

Aside from its enormous output the engine has a great commercial importance in its ability to utilize low grade oils in addition to pure petroleum, as tar oils, and oils produced from the distillation of shale and lignite will operate the engine under satisfactory conditions.

A further reason for the prominence given this engine lies in the fact that it has broken the monopoly of coal. At the Turin Exhibition, last year, a steam turbine and a large Diesel engine, both made by Franco Tosi, of Milan, and set up on the same stand, were worked together with the same liquid fuel. The boilers furnishing steam to the turbine

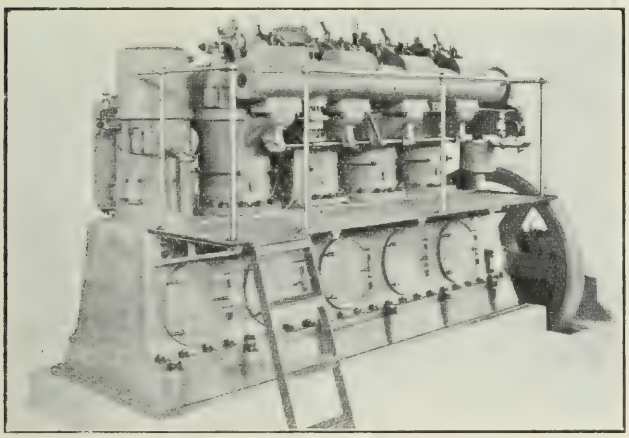

Fig. 1.—View of Engines of the "Selandia."

burned crude oil. The difference between the two plants was therefore this: for the working of the steam engine the whole boiler plant with its chimney, fuel-supply apparatus, purification plant for feed water with feed pumps, extensive steam pipes, condensation plant with water pumps and an enormous water consumption, had to be provided, with the final result of consuming 2½ or more times the fuel per horse-power required by the Diesel engine standing beside it. The latter, being an entirely independent engine without any auxiliary plant, took up its crude fuel automatically and consumed it direct in its cylinders without any residue or smoke. A better proof can hardly be imagined, even for the non-technical man, that except in special cases the steam engine cannot compete economically with the oil engine. It is hardly possible for a country which produces no coal, like Italy, to develop a great industry based on the steam engine, and this is one reason for the exhibition at Turin of about thirty Diesel engines of various types and sizes, and made in different countries.

Thus the Diesel engine has doubled the resources of mankind as regards power-production, and has made new and hitherto unutilized products of nature available for motive power. The Diesel engine has thereby exercised a far-reaching influence on the liquid-fuel industry. It has been proved by recent geological researches not only that there is probably on the globe as much, or perhaps even more liquid fuel than coal, but also that it is more conveniently distributed as regards its geographical position.

Although the engine has been used to a considerable extent for power-house and factory purposes, it is the prominence given it through its adaption to marine and naval propulsion that has brought the engine so prominently before the public. The first oil propelled liner of large dimensions to be a commercial success was the "Selandia" of the East Asiatic Company, a ship of 9,800 tons displacement and was built by Messrs. Burmeister and Wain, Copenhagen, there are two engines, driving twin screws, each engine consisting of a set of eight single-acting cylinders 20⅞ in. in diameter by 28¾ in. stroke, working on the four-stroke cycle. Messrs. Burmeister and Wain have adopted this type of Diesel engine to obtain greater reliability, owing to the absence of temperature troubles, the completeness of scavenging, and the better balance of the reciprocating parts than has so far been considered obtainable with two-stroke cycle engines of equal power and of the same cylinder dimensions. That this policy is justified was proved by the running of the engines on the demonstration trip from London to Antwerp.

The cam-shaft and manœuvring-shaft are supported on brackets bolted to the crank-case, making the removal of the cylinder-heads for the examination and adjustment of the reciprocating parts quite simple, as neither of these two shafts need be disturbed in any way. Skew-gearing—the most general method of drive for the cam-shaft—has in this design been displaced by cast-steel spur-wheels, although it is retained for the manœuvring-shaft, which is only in action to bring the opposite motion cams into play, to lift the rollers with their push-rods and to replace them. The skew-gearing is operated by a compressed-air motor taking air from the starting air reservoirs. There are two fuel-pumps for each set of eight cylinders, each pump being of sufficient capacity to supply the whole engine, and, according to the gauge, the pressure of the oil on the exit from the pump was 1000 lb. per sq. in. This gives an indication of the extreme accuracy of machining and fitting which is essential for this work.

With regard to the auxiliary and machinery for the main engines, it is quite evident that no pains and no expense have been spared to render this plant as immune from break-down as is possible. Hitherto it has been with the compressed-air plant that the difficulties have been experienced, causing break-downs and necessitating in several ships the fitting, after completion, of a donkey boiler to supply steam to ensure the reliable working of the auxiliaries. On the Selandia the compressed air for starting and for fuel injection is supplied from the two three-stage 300 lb. per sq. in. compressors driven by the Diesel engines, which are also coupled to the generators for the electric power. In the next ship by these builders it will be so arranged that each set will be equal to the total normal work, so that even if one set were to break down, the maximum speed of the vessel would be maintained. A fourth-stage compressor in the forward end of each main engine receives the air from the 300-lb. com-

pressor, and compresses it up to the pressure required for the injection and pulverization of the fuel—i.e., 900 lb. per sq. in. Each of these high-pressure compressors is equal to the total work of both engines, and, further, an additional length of working stroke can be given to either when it is desired to increase the output of 900 lb. per sq. in. air for the recharging of bottles, &c. It is also further possible to fit a delivery valve with connections to a working cylinder in place of the exhaust valve, so as to augment further the store of the starting medium, by utilizing the compression stroke of the cylinder. The engine turns well, and without appreciable loss of balance when firing in seven or even six of the cylinders of one engine. As a final stand-by, a steam-driven three-stage 900 lb. per sq. in. air-compressor is installed forward of the oil-fired donkey boiler which is placed aft in the engine-room between the thrust shafts.

The fuel injection air is stored in two working bottles of German manufacture, with solid ends welded in by a patent process, placed vertically amidships between the compressed-air manœuvring engines. Drain-pipes to the bottom of the working bottles are fitted, and periodic blowing down ensures freedom from moisture, with its consequent corrosion. Two spare bottles are placed against the forward bulkhead, and it is so arranged that connections can be made between the independent fuel-injectors, one working and two spare air-bottles, to keep the main engines running should their air supply fail, due to leakage, &c. It is interesting to note that both the auxiliary Diesel engines have also a fourth-stage air-compressor (300 lb. to 900 lb. per sq. in.), on the forward end of their crank shafts. The starting air, at 300 lb. per sq. in, is stored in four reservoirs—two for each engine—with dished ends, which are hung from the deck above. One reservoir is normally sufficient for each engine.

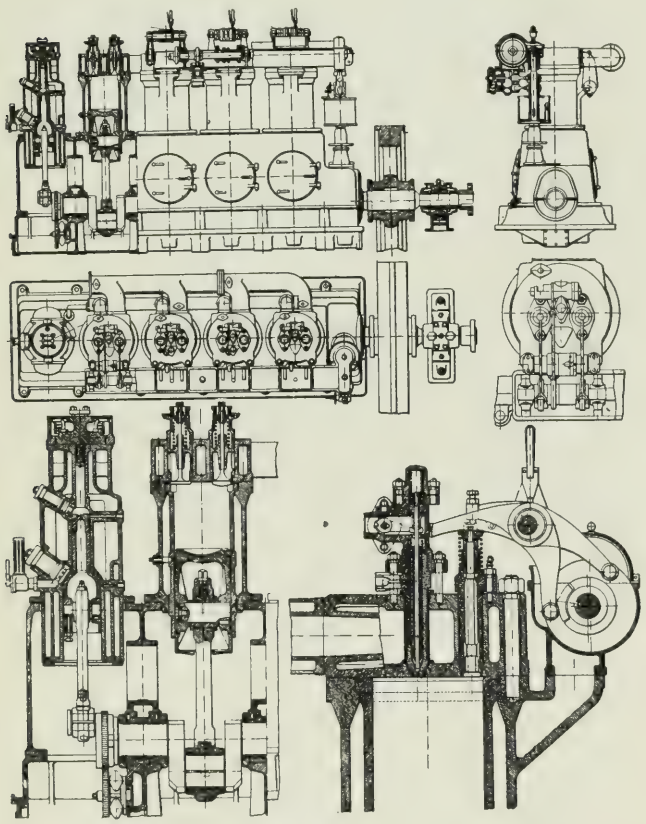

Fig 2.—Details of 200 Horse-power Four-cycle Diesel Engine.

Lubrication oil to the main bearings is forced in at 10 lb. per sq. in. pressure by one of two electrically driven plunger pumps through the main bearings, crank-shaft, and crank-webs to the pin and bottom end bearing, thence up the connecting-rod to the crosshead bearing, and up the piston-rod to the piston, coming down the piston-rod again to the guides, when the oil is partially cooled, and thence led outside the crank-case and discharged through a filter to the sump in the bed-plate. This discharge supplies the means whereby the engineer on watch can assure himself of the quantity of flow and the temperature of the oil. Each lubricating oil-pump is in circuit with a cooler of ample proportions to cope fully with the onerous temperature conditions of the Red Sea and the tropics. There are two cooling-water centrifugal pumps, electrically driven, to supply all the cooling for the main and auxiliary engines, main and auxiliary compressors, lubricating oil, &c.; two duplicate electrically-driven three-throw plunger-pumps, one for sanitary purposes, two for the bilges, with connections to the ballast tanks, which are usually pumped out by a compressed-air-driven ballast pump. The compressed air also operates the fuel-oil pumps, which draw the fuel-oil from the double-bottom tanks to two daily service tanks of sufficient capacity for 12 hours' working, which are placed on the engine-room tops. The function of these service tanks is to permit of the settlement of any water pumped, together with the oil from the double-bottom tanks, which are filled with ballast when empty.

It is claimed that the adoption of Diesel engines has increased the cargo-carrying capacity by 1,000 tons, chiefly owing to the absence of coal-bunkers, since an engine and boiler room for the same power would only occupy two or three frame spaces more than the Diesel engines. The saving in weight must be small, since the machinery of the Selandia must weigh some 400 to 450 tons, which is equal to 250 lb. per brake-horse-power for the main engines alone.

Details and views of the engine are shown in Fig. 2. This shows the mechanical make up of the engine which is a good example of a modern Diesel engine.

NEW DEVICE FOR LAUNCHING LIFEBOATS.

Sir Bryan Leighton has invented a new device for launching lifeboats, and a model of the contrivance has recently been shown at the Hotel Cecil, London. The idea is to launch lifeboats from both sides of the ship by an apparatus on the water-shoot system. The end of the shoot or launching way rests on a pontoon, which in the case of a ship of the dimensions of the Olympic would be 40 feet long, 8 feet deep, and 10 feet wide. A ship of the size of the Olympic would carry two of these launching ways, one on either side. They are attached to the side of the ship by means of a swivel, and lowered by a crane which swings them free of the ship into the water. The passengers enter the boats on the deck. The boats are run along a set of rails to a turning table immediately at the top of the shoot, and are lowered down to the water level by means of a wire hawser. Towards the end of the shoot is a knuckle, which causes the bow of the lifeboat to have a tendency to shoot upwards on touching the water. The launching way can be placed at an angle, according to the state of the sea. It is assumed that an experienced seaman is placed in each boat, and directly he gets within a couple of boat-lengths of the water he manipulates the releasing apparatus; the boat then shoots into the sea, and the rope is pulled up for another boat.

A Board of Trade expert spent an hour in examining the device, and did not offer any serious objection to it. The inventor claims that it is a simple and inexpensive contrivance, and it is understood that it will be brought before the notice of the leading shipping lines.

AN IMPROVED CONCRETE PAVEMENT.*

By Mr. E. W. Groves, City Engineer, Ann Arbor, Mich.

Some years ago the writer became convinced that the forms of street pavement commonly used were too expensive to come into general use, especially on residence streets, in both our large and small cities and on country highways. If the demands of modern traffic were to be satisfied, a much cheaper form of pavement must be devised, yet one having all the essential characteristics of permanency and low cost of maintenance. With this idea in view, concrete pavements, constructed in the ordinary manner, were inspected and it was found that while the concrete had the strength to support the weight imposed upon it, it was readily susceptible to the abrasive action of traffic as well as to changes in volume, which produced cracks, which in turn, under the action of wheels and hoofs, soon became enlarged into ruts. Previous to this inspection the writer had caused a section of a street paved with asphalt blocks, which was rapidly disintegrating, to be covered with a thin coating of crude coal tar and sand. The effect was wonderful. The new coating took all of the wear which had formerly been on the asphalt blocks and preserved the pavement, which is in good condition to-day. The pavement is less noisy than before, and not as slippery as sheet asphalt.

For some time the citizens living on a certain block in this city had desired that it be paved. But they were unwilling to pay such high prices as had been charged for pavement. In an effort to satisfy their request the writer conceived the idea of laying a concrete pavement and covering it with a coating of tar and sand. Accordingly, with the consent of the city authorities and the property owners, we paved one block, of 1,883 sq. yds., with concrete, covering the surface with hot crude coal tar and sand, using about one-half gallon of tar to each square yard of pavement. After this pavement had passed through the winter of 1909 and 1910 and our citizens had an opportunity to judge its merits, petitions were presented asking for over 20,000 sq. yds., which were laid during the summer of 1910. During the winter and spring of 1910 and 1911 petitions were presented asking for about 70,000 sq. yards., of which 64,000 sq. yds. were laid and at the present time we have on file petitions asking for 140,000 sq. yds. more, which will be laid as soon as conditions are favorable.

Let us return to the subject of the change of volume of concrete. The writer, of course, was aware that such a change occurred. He had his ideas, as all of you have. But it remained for Prof. A. H. White, of the University of Michigan, to tell us the reason for the greatest volume-change. In a paper read before the American Society for Testing Materials and published in their Proceedings, Vol. XI., 1911, Prof. White gave the results of certain experiments performed by him. In his introduction he speaks of the "Constancy of volume" of cement mortars and calls it a "misnomer." Any one can see from cracked walls, sidewalks and other concrete structures, whose failure is not due to the settling of foundations, that there is some inherent characteristic which causes cement, cement mortars, and concrete to change volume if exposed to the weather.

He says: "The change of volume of concrete due to changes in temperature has been determined with considerable accuracy to be per unit length 0.0000055† or 0.00055 per cent. per degree Fah. There are, however, other changes due to the chemical process of setting and hardening which are barely mentioned in even the more important treatises and other variations due to the wetting and drying of the concrete, whose very existence is practically unknown."

He deals with these latter and previously unknown changes. From earlier experiments by Schuman, Gary, Considere, and Campbell and White it was definitely determined that neat cements, hardening under water, expand at a decreasing rate for years, and that neat cements, hardening in air, contract similarly, and that cement-sand mortars act in the same manner as neat cement, but to a less degree.

Mr. White has been experimenting for twelve years or so with neat cements and various sand mortars. He has found that neat cement, when immersed in water for a period of three years, showed a linear expansion of from 0.10 to 0.15 per cent., nearly all of which occurred during the first year. When these bars were allowed to dry in the room (temperature about 70 degrees Fah.) for 65 days they had contracted to their original volume and in some cases 0.05 per cent. less. Upon re-immersion in water they regained all their previous expansion in about one day, and some expanded more than they had ever done before. In one specimen of natural rock cement the expansion in water during the same period of time and under the same conditions went as high as 0.55 per cent., but on drying contracted +0.25 per cent. He also tested in the same manner various

View of Street in Ann Arbor, Mich.

bars composed of a 1:3 mix of sand mortar and compound bars of neat cement and 1:3 mix. The first bars behaved like the neat cement, only in a less marked degree. In the compound bars the neat cement part acted in the same manner and in the same degree as the other neat cement bars, while in the 1:3 mix there was a tendency to lag in both expansion and contraction. This difference of expansion, of course, set up sheering stresses at or near the line of demarcation. In some cases these sheering stresses were great enough to rupture the bars.

To take some examples of this from actual practice, the writer can site numerous cases in Ann Arbor where the sidewalks have broken apart, that is, the top course broken loose from the bottom course, and in every instance it could be seen that the line of fracture did not conform to the line of demarcation, but was below in the leaner mix. There was a film of the base concrete from 1/64 to ⅛ and in some cases ½ of an inch thickness clinging to the top course, showing that the failure was not due to poor bonding between the two courses. Doubtless every one of you have seen a sidewalk buckle up in an inverted V. This

occured in some of the walks on the campus of the University of Michigan, and on several of the city streets in walks that have been laid from one to ten years. The peculiar thing about the failure was that it occured during the summer months, thus precluding any result of the frost action. There remains only the moisture to blame, since the expansion due to heat is so small. To the writer's mind the foregoing proves conclusively that the great destruction of concrete pavements is due, first and foremost, to the alternate wetting and drying when they are unprotected.

Now, this coating of bitumen and sand is waterproof. Thus the greatest cause of the destruction of concrete pavement is eliminated. The writer does not care to go into the question of water from below or sub-drainage. The greater portion of the streets of the city of Ann Arbor are of a gravelly soil and thus drain themselves. However, a portion of one street is clay and the pavement was laid directly upon it, and shows no ill effect up to the present time, and none is expected.

The pavements laid during the seasons of 1909 and 1910 were trated with crude coal tar and, while this material was fairly satisfactory, it was evident that a distilled product having a uniform consistency would be better. Experiments were made with various products of the distilled tar, tarvia, and asphalts with various degrees of viscocity. These were all more or less unsatisfactory, more especially the products containing asphalt oils. As objectionable features made their appearance efforts were made to overcome them. Extensive laboratory tests produced a bitumen which has none of the objectionable features of the crude tar, tarvia and asphalt. This bitumen, when applied to the concrete at a temperature of 180 degrees Fah., is thin enough to bond into the interstices of the base, making an impervious surface.

The pavements laid up to the present time have been made up of two layers of concrete, viz.: a base 4½ inches thick composed of one part of cement to eight parts of bank run gravel, and top layer 1½ inches thick composed of one part of cement to two parts of gravel passed through a screen having a one inch mesh, the cop course being applied immediately after the bottom course is laid to insure a good bond. Since the top coat of a pavement laid in this manner contains more cement than the bottom, and since it has been shown that such a construction tends to produce internal shearing stresses; there is a possibility of separation of the two layers. While no action of this nature is apparent in our pavements, due to the waterproofing effect of the bitumen, to be on the safe side, all our future work will be one coat work, using approximately one part of cement to 4½ parts of bank run gravel.

It has been the practice to leave an expansion joint about ¾ of an inch wide at each curb, and also every 25 ft. transversely of the street. After the surface of the concrete has been trowled to conform to the crown of the street, and when it is partially set, a light wire broom is used to roughen it in order to furnish a better surface for the adhesion of the bitumen. Later the expansion joints are filled to a little less than one inch of the surface, with sand upon which is poured hot bitumen, making the joint filling flush with the surface of the concrete. After the concrete has become thoroughly set and is dry and clean (being swept if necessary) one half gallon of bitumen heated to a temperature of 180 degrees Fah. is spread over each sq. yd. of the surface of the pavement, and while this bitumen is still hot and soft it is covered with a layer of torpedo sand ranging from ⅛ to ¼ inch, using about one cubic yard to each 250 sq. yds. of pavement. The street is then immediately opened to traffic which grinds the sand into the bitumen and products a rubbery surface, black in color, almost noiseless, and having the appearance of sheet asphalt.

As to the cost of maintenance, I can only speak from an experience of three years. With upwards of 80,000 sq. yds. of this pavement, constructed during the last three years, not to exceed $30.00 has been expended on repairs, and the pavement is in good condition to-day. The owner of a frame house, in building, does not consider that the first painting will last the life of the house. He plans for the expense of repainting every few years. Its initial cost is low enough to allow for maintenance charges. It must be kept in mind that there is no pavement that is entirely free from maintenance charges. In summing up the advantages of this pavement, it may be said that the concrete, if properly and honestly constructed, is strong enough to sustain the weight of the traffic which passes over it. The bitumen prevents the absorption of water by the concrete and thus preserves it from cracking. The change of volume due to temperature is negligible. The combination of torpedo sand and bitumen gives a wearing surface which is unexcelled. The construction cost is low as compared with other pavements and requires no cumbersome and extensive plant. When it becomes necessary to put pipes of any sort beneath the pavement repairs are easily and perfectly made, no ridges or hollows being produced. With a firm sub-base no reinforcement whatever is necessary for the stability of the pavement. With the manner of filling the expansion joints described above, there is no chipping or crushing of the concrete at the edges. If the filling is carefully done it is impossible to point out an expansion joint in the finished street. When the hot sun of summer heats the pavement there is absolutely no free bitumen coming through and sticking to the feet. It does not "bleed." Our citizens are so well satisfied with it that they will not consider any other form of pavement. It is, indeed, a most suitable pavement for country highways, parks and boulevards, as well as city streets. With gravel banks, ledges of rock, marl clay and sand, the essential elements of concrete so profusely distributed throughout this country, the bitumen easily obtained, a pavement that can be laid for about one dollar a square yard based on Ann Arbor prices, and that is durable, noiseless, and pleasing to the eye, I can see no reason why it should not become the most universally used of any or all of the various pavements before the people to-day.

LARGE WATERWORKS.

The protracted negotiations between the governments of South Australia, Victoria and New South Wales in regard to the proper utilization of the waters of the River Murray for navigation and irrigation have been advanced another stage, an agreement authorizing South Australia to construct storage works at Lake Victoria having been signed by the premiers of the three states concerned. Lake Victoria is situated in New South Wales, and about 14 miles in a direct line above the boundary of South Australia.

The agreement, which is subject to ratification by the parliaments of the three states, contains provisions for the transfer of the site of the proposed works from New South Wales to South Australia. It is estimated that the reservoir which will result from the improvement of the present Lake Victoria will have a storage capacity of 1,500,000,000 cubic feet, and it will approximately cover an area of 30,000 acres. There will be two weirs and locks associated with the reservoir, the exact sites of which are not yet determined. A clause in the agreement provides that the compact shall not be regarded as a settlement of the vexed question of the apportionment between the states of the waters of the Murray.

TESTS ON REINFORCED-CONCRETE BEAMS.

The Structural Materials Laboratory of the United States Geological Survey was founded at St. Louis, Mo., in 1904, in connection with the world's fair being held there at that time. At this laboratory there was carried on for six years extensive tests of various structural materials, including a number upon various kinds of concrete and reinforced-concrete specimens. The scheme of the laboratory in these latter tests was to proceed from the simplest forms of cement, mortar and concrete through concrete tension and compression tests to various reinforced-concrete beams and columns. In July, 1910, by act of Congress the laboratory was transferred from St. Louis to Pittsburg and from the direction of the Geological Survey to the United States Bureau of Standards, under whose auspices further work will be carried on. Preliminary reports of the tests on concrete materials include Bulletin No. 331 of the U.S. Geological Survey, which describes the tests of Portland cement mortars and their constituent materials, and Bulletin No. 344 of the U.S. Geological Survey, which covers the tests of plain concrete beams. The next step in the testing, that is the test of plain reinforced-concrete beams, was completed at the St. Louis laboratory, but the data for the test were transferred to the U.S. Bureau of Standards when the laboratory was transferred and have been just published by that bureau as a "technologic paper." We give below a short description of its contents.

The tests comprise simultaneous compression tests on 8 x 16-in. cylinders and 6-in. cubes and simply reinforced beams with varying percentages of reinforcement. The series consisted of 336 beams (three of which were not tested) together with the corresponding cylindrical and cubical test pieces for compression tests and 48 bond test pieces to determine the adhesive strength of the aggregates used. Representative material of four classes of aggregate, gravel, crushed granite, crushed limestone and cinders, were used in making up the test pieces which were tested in triplicate at the ages of 4, 13, 26 and 52 weeks, respectively. The report says:

The report of these tests has been confined exclusively to a presentation of test data in such a way as to indicate with considerable certainty the various elements which affect the design of architectural and engineering structures. Studies have, therefore, been made near maximum load between external load conditions, as measured by the bending moment, and resistance of the beam as determined by the resisting moment. There is included the relation between the unit stress at maximum load and the yield point of the reinforcement.

Studies have been made for maximum load and for unit stresses of 16,000 and 32,000 lb. of the relation between the effective percentage of reinforcement and (1) the resistance $\frac{M}{bd^2}$ of the beam as measured by ——, (2) percentage depth to the neutral axis, (3) unit compressive stress in the extreme upper fibre, (4) the deflection at the centre of the beam. The results are presented diagrammatically and in greater detail in tabular form. The change of such relation with age and the difference due to the nature of the aggregate have also been determined and are presented.

The development and spacing of the tension cracks below the neutral axis for the various aggregates, ages, and percentages of reinforcement is plainly shown by photographs of the beams.

There is also included a study of plain concrete in direct compression. The growth in strength with age and the increase in stiffness, as measured by the initial modulus of elasticity, are clearly brought out. The variation with age of the ratio of the yield point to the ultimate strength for the different aggregates has been determined.

No extended discussion of the theory of reinforced concrete is attempted in this bulletin, and theoretic formulas have been introduced only where necessary for the intelligent presentation of the data. The formulas used are, however, not original with the bulletin, but are based on assumption which are thought to approximate the truth.

The preliminary description includes accounts of the methods of tests of the cement, the sand, the aggregates, the reinforcement and the separate test pieces. Following that is a chapter on the result of tests, which discusses the tables which include all the data of the tests and in addition takes up the analysis of the beam at the first crack, the analysis at maximum load and the effect of variations in the percentage of reinforcement. Finally, in this portion is a discussion of the compression tests, taking up the influence of age on relative strength of cubes and cylinders and upon the modulus of elasticity and yield point and the ratio of the yield point to the ultimate strength.

The variation in the constants entering into the composition of the beam and the completeness of the record of the tests are such that a great number of tables and diagrams are needed to present the results. At the same time, these results are most comprehensive and permit of a thorough study of the behavior of simple reinforced-concrete beams.

Conclusions.—As a result of the tests, the authors have made the following conclusions:

Reinforced Concrete in Flexure.—The unit elongation of the extreme lower fiber at the time of the occurrence of the first crack is 0.00012, for stone and gravel concrete, 0.00018 for cinder concrete, and equals the unit elongation of the lower fiber at rupture of a beam of the same concrete without reinforcement.

The unit elongation of the extreme lower fiber at time of the occurrence of the first visible crack increases with the percentage of reinforcement.

The distance between cracks due to tension varies with the percentage of the reinforcement, slightly with the kind of aggregate, and is independent of the age of the concrete.

The ratio of the unit stress in the reinforcement at maximum load to the yield point varies with the percentage of the reinforcement, is independent of the age of the concrete, and shows no regular variation with the initial modulus of elasticity of the concrete.

The unit bond stress at a load just below maximum, for a unit stress in the reinforcement somewhat less than the yield point, is almost constant and equal to about 120 lb. per sq. in. It increases slightly as the percentage of the reinforcement increases, increases somewhat with age, and with the strength of the concrete.

Basing the resisting moment of a reinforced-concrete beam on the tensile stress in the reinforcement, and neglecting the tensile resistance of the concrete, the ratio of the resisting moment to the bending moment is always less than one between 0.5 per cent. and 1.7 per cent. "effective" reinforcement. This ratio is independent of the kind of aggregate used, decreases with age, and increases with the percentage of reinforcement.

The behavior of the reinforced-concrete beam, having the reinforcement in two horizontal planes is identical with a beam having all the reinforcement concentrated in one plane, and equal in amount to the reinforcement in the lower plane plus that in the upper plane multiplied by the ratio of the distances of the upper and lower planes from the neutral axis.

The percentage depth of the neutral axis below the top of the beam increases with the percentage of reinforcement and increases or decreases with different amounts of reinforcement as the intensity of loading increases, depending upon the ultimate strength of the concrete as influencing a compression failure, and the relative stiffness of the concrete for varying degrees of stress as determined by the character of the stress deformation diagram of the cylinders (fixed by the proportions, consistency, kind and age of concrete).

For all practical purposes the percentage depth to the neutral axis for a given unit stress in the reinforcement may be taken as independent of the age of the concrete.

The character of the concrete as measured by its modulus of elasticity exerts an influence on the position of the neutral axis.

For any given percentage of effective reinforcement the moment of resistance varies as the ordinates of a straight line, and based on the moment of resistance of a plain concrete beam the moment of resistance for a reinforced-concrete beam is proportional to the effective percentage of reinforcement.

The moment of resistance is appreciably affected by the character of the aggregate used and the age of the concrete.

For a given unit stress in the reinforcement the deflection increases with the percentage of "effective" reinforcement and increases as the modulus of elasticity and ultimate strength of the concrete decreases.

The deflection of a reinforced-concrete beam increases in direct proportion to the increase in the unit stress in the reinforcement.

The unit compressive stress in the extreme upper fiber varies with the percentage of effective reinforcement as the ordinates to a straight line.

Excepting cinder concrete for the earlier ages and low percentages of effective reinforcement, the unit stress of 16,000 lb. per sq. in. in the reinforcement corresponds to a unit compressive stress in the extreme upper fiber of at least 1,000 lb. per sq. in.

Concrete in Compression.—The conclusions as to the general effect of age on the various elements (ultimate strength, initial modulus of elasticity, and yield point) that determine the value of a given concrete are probably of fairly general application.

It should be recognized that the results obtained for each class of material—i.e., granites, limestones, gravels, etc.—used in these tests may not be applicable to other materials of the same class obtained from a different source. There are too many elements affecting the strength of concrete to warrant the assertion that because an individual of a class—i.e., granite—gives excellent results, that, therefore, all granites will give equally good results. The gravel used in these tests has smooth, round surfaces but developed a compressive strength but little inferior to that of the granite, and appreciably greater than that of the limestone. Yet it cannot be stated that the use of any given gravel for concrete is permissible, because this particular sample, which originated from a hard, flinty rock and is well graded, gives excellent results. A gravel deposit will necessarily partake of the physical properties of the rock from which it is derived and no good results can be hoped for by the use of a gravel which originated from a soft, chalky limestone or from some weak, cleavable shale or sandstone. The compressive strength of the stone affects the compressive strength of the concrete in which it is used in too great a degree to warrant the neglect of the consideration of this influence, while even for the same stone, the strength of the concrete will be greatly influenced by the uniformity or nonuniformity of the grading.

Again, for equally good grading, the material which grades down from the larger particles will nearly always show the greater strength. The effect of a large amount of dust in decreasing the strength of the concrete should not be overlooked. It must be recognized that the quality of the sand used in making the concrete—i.e., its hardness, size and grading, the presence of a large amount of very fine material—are all elements which will modify conclusions as to the excellence of a given stone or gravel.

From a consideration of the above facts it is always advisable to make careful investigation of the materials available, even though the costs of tests seem excessive.

The weight per cubic foot for a 1:2:4 stone and gravel concrete may be taken as 150 lb. and a cinder concrete 120 lb.

The ultimate strength of 2,000 lb. per sq. in. for a 1:2:4 concrete at the age of four weeks, frequently the basis for unit stresses, was exceeded by almost 50 per cent. for the granite and gravel and by 25 per cent. for the limestone concrete, but the value found was 20 per cent. less than 2,000 lb. per sq. in. for the cinder concrete.

The ultimate compressive strength of concrete shows a substantial increase from an age of four to one of 52 weeks, the strength at four weeks being about 65 per cent. of that of 52 weeks.

The yield point at the age of four weeks averages about 0.30 the ultimate strength and for stone and gravel concretes is well above 500 lb. per sq. in., but for cinders is somewhat less. The yield point shows a substantial increase with age.

The compressive stress, gross deformation diagram of concrete may be represented by a straight line up to a unit stress 1.5 times the yield point with a maximum error of about 6.5 per cent. A working formula for reinforced-concrete in flexure, based on a constant stress deformation diagram for concrete in compression, will therefore, give correct results up to an extreme unit fiber stress of 0.30, the ultimate strength. This would correspond to a factor of safety of about 3 and for a unit fiber stress 50 per cent. greater the error will not exceed 7 per cent.

The initial modulus of elasticity at the age of four weeks exceeds 2,500,000, the amount usually specified, by about 85 per cent. for gravel, 70 per cent. for granite, and 45 per cent. for limestone concrete, but is 35 per cent. less for cinder concrete. The increase in stiffness with age as measured by the modulus of elasticity, while marked, is not nearly so great as the increase in strength.

The ultimate strength of concrete in compression as given by the cylinder test is always less than that given by the cube test, the ratio being about 75 per cent. at the age of four weeks, and showing a substantial increase with age, due to the greater percentage increase of strength for the cylinders.

Reinforcement.—A study of the 1,260 tests of the steel used as reinforcement for the beams herein recorded shows that: (a) For even practically identical ultimate strengths there is considerable variation in the percentage of elongation and reduction of area. (b) The yield point bears no relation to the ultimate strength.

A NEW COMBINATION OF METALS.

A French metallurgist has manufactured an alloy with a hardness of steel and of great tensile strength by the addition to copper of chromium, aluminum, nickel and zinc at certain temperatures, which are maintained for specified lengths of time.

THE INTERNATIONAL CONGRESS OF NAVIGATION.

The twelfth session of the International Congress of Navigation met this year in Philadelphia, and the meeting has just closed. The members of the Congress are men engaged in, or interested in, matters connected with waterway improvement and maintenance, rivers, canals, harbors, and terminal works, and practically all countries of the world are represented. As the most of the work covered by such a body of men is work which comes under the control of the different Governments, a very large proportion of the members of the Congress are Government officers, and many of them were officially delegated to attend the Congress. For this reason, no doubt, and because of the importance of the men in attendance, the Dominion Government has requested the Canadian Society of Civil Engineers to act as hosts in the reception of a party of members of the Congress who are visiting the eastern portion of Canada this week. A party of members of the council of the society and representatives of the eastern branches met the delegation on their trip to Sault Ste. Marie yesterday, and are now accompanying the party on their trip down the Great Lakes to Quebec. The Dominion Government is to be congratulated on their move to entertain the members of this Congress, for they are a most important body of men. Their impressions of Canada, as obtained from this trip, will be most valuable to the country in the future. The Government must also be congratulated in choosing the Canadian Society of Civil Engineers to act as the official hosts on this occasion, for the members of the society are better equipped to present the interesting features of our inland system of navigation and our harbor equipment than any other body of men.

CANADIAN ELECTRICAL ASSOCIATION.

The Canadian Electrical Association are holding their annual meeting in Ottawa next week. A programme of the meeting will be found in this issue of *The Canadian Engineer*. Last year's convention, which was held at Niagara Falls, Ont., was one of the best meetings ever held by the society. The attendance was large, the papers were good, and there was a strong interest shown throughout the meeting. As is generally known, this association is now affiliated with the National Electric Light Association, the union being made about two years ago. Evidently it has been a good thing for the association, for a renewed interest has been developed which speaks well for the future. The objects of the Canadian Electrical Association are to advance the professional interest and knowledge of the members in the various branches of applied electricity by holding meetings for the reading and discussion of papers and general interchange of opinions, to foster friendly intercourse between the members, and to promote the commercial interests of members engaged in the sale of electric light, heat and power. The association in its aim does not conflict in any way with the other engineering societies of the Dominion, and serves in a very real way to develop a spirit of friendliness and cordiality among the members of the profession interested in that branch of engineering. No doubt this year's meeting at Ottawa will be well attended, and we wish for the association a most successful meeting.

THE PUBLIC HEALTH DEPARTMENT OF ONTARIO.

During the last session of the Provincial Legislature an Act was passed dividing Ontario into seven districts under the Public Health Department. While the exact boundaries of the various divisions have not as yet been announced, it is understood that this will soon be done, and that the appointment of the seven Public Officers who will be placed in charge will be made almost immediately. The Government is to be congratulated on having taken this move, and there is little question but that under the present Provincial Health Officer the work will be carried on most effectively. The work of the Department will be much more effective under the new régimé, for the heads of the different districts will be able to exercise a greater degree of supervision over the different elements and conditions which affect the public health question of the Province. No doubt the utmost care will be taken in choosing the district officers, for they must be men not only with a knowledge of the problems of sanitation, etc., with which they have to deal, but they must be men of considerable breadth of view. The engineering profession will watch the development of this department of governmental activity with considerable interest, for these new officers will be more or less intimately associated with the solution of many engineering problems.

CITY ENGINEER.

An anomalous condition has arisen with regard to the appointment of the Commissioner of Public Works at Toronto. Mr. R. C. Harris, an eminently capable man for the position, has received the appointment, and with it the title of City Engineer. Mr. Harris is not a technical man, never having had any engineering training or experience, yet it is claimed, in order to secure the maximum of service, it is necessary that he carry the designation of engineer. The acting City Engineer, Mr. Powell, must, therefore, handle all of the technical phases of the city's administration, and be, in fact, city engineer, but he will not be able to have the title. The term "engineer" begins to mean little when city councils can give it to those without training. If certain city statutes give the City Engineer specific powers and duties which, from his engineering training, he is best able to handle, it is decidedly a mistake to hand these powers and duties over to a non-technical man, who must depend for his engineering knowledge on a subordinate. It is unfair to the acting city engineer not to give him the title if he must carry the responsibilities and duties of the position.

EDITORIAL COMMENT.

The investigation into the collapse of the south wall of the Neilson building, which occurred a short time ago in Toronto, has been concluded, and the verdict of the coroner's inquest has been published. We had hoped to cover the whole question of the collapse in this week's issue of *The Canadian Engineer*. Unfortunately however, this has to be delayed until next week. In our issue of June 20th a résumé of the investigation and a full account of the whole affair will be given.

A new permanent pavement between Toronto and Hamilton is being advocated. A first-class highway connecting these cities would be of inestimable benefit to both, and would serve as an object lesson on the advantages to be obtained from good roads. Ontario is becoming so populous and the conditions of traffic on the highways are becoming so severe that more attention must be paid to the question of the permanency of the roadbed.

GENERAL NOTES.

The table shows for fifteen stations, included in the report of the Meteorological Office, Toronto, the total precipitation of these stations for May, 1912:

	Depth in inches.	Departure from the average of twenty years.
Calgary, Alta.	1.40	—0.08
Edmonton, Alta.	2.30	+0.54
Swift Current, Sask.	3.40	+1.18
Winnipeg, Man.	3.60	+1.59
Port Stanley, Ont.	2.40	+1.01
Toronto, Ont.	5.92	+3.10
Parry Sound, Ont.	6.00	+2.95
Ottawa, Ont.	5.60	+3.08
Kingston, Ont.	5.70	+3.60
Montreal, Que.	5.10	+1.75
Quebec, Que.	6.90	+3.75
Chatham, N.B.	6.90	+4.08
Halifax, N.S.	6.30	+2.64
Victoria, B.C.	1.60	+0.34
Kamloops, B.C.	0.30	—0.73

LAND DRAINAGE BY PUMPING.

Drainage by means of pumps has been carried on in European countries for the last hundred years, and has been rapidly increasing in the United States during the last twenty-five years. Through such extensive experience, including numerous failures, a considerable amount of knowledge is now available on the subject of the proper arrangement and the requisite capacity of pumping plants.

Among the plantations along the Gulf of Mexico, pumping has been in vogue for a long period. In Illinois, although first tried about twenty years ago, little was accomplished prior to 1900, but by the spring of 1910 ten plants were in operation, covering a total area of about 85,000 acres. The greater part of the lowlands along the Illinois River have been already reclaimed in this manner, and, as the lands are in the heart of the corn belt and possess a heavy, rich black soil, their value has led to a greater activity in drainage reclamation in the immediate vicinity than has existed in most other portions of the country.

BRIDGE WILL BE USED BEFORE COMPLETION.

The municipal council of Winnipeg, in order to provide traffic facilities across Osborne Street with all possible speed, have offered a bonus of one thousand dollars to the contractors providing they have the three steel spans in place and a temporary planking by the evening of July 9th next.

SANITARY SURVEY OF THE OTTAWA RIVER.

In the seventeenth annual report of the Board of Health of the province of Quebec, Mr. James O. Meadows, the sanitary engineer for the board, gives a report on a sanitary survey of the Ottawa River. His report presents many matters of interest and has been published in a pamphlet form recently by the Provincial Government, for general distribution. We present herewith an abstract of Mr. Meadow's report.

This report of the sanitary condition of the Ottawa River was undertaken to study the river as a source of domestic water supply and its relations to public health, and the information contained is based upon results secured from analytical data recently completed and by analytical data which was available from previous local studies.

These studies relate to the potability of the domestic water supplies, in regard to their relation to sewage, refuse, and industrial wastes discharged into the river at points above those from which such water supplies are obtained. These questions have been further studied by the aid of vital statistics and typhoid fever data so as to obtain their relations to the public health.

The work has been confined to a study of the main river from a point above Pembroke to Montreal, and the main object has been to determine to what extent the Ottawa River is used as a source of public water supply.

The work is taken up under the following headings:

1. Conduct of investigation.

2. The Ottawa River. Information as to its area, length, population on water shed, and a description of its special features.

3. Results of investigations.

Summarized data in regard to the population using the Ottawa River as a water supply, for the discharge of sewage, and manufacturing waste. The character of Ottawa River water as indicated by analytical data, together with data on water purification and typhoid fever statistics.

4. Conclusions.

Table No. 1.—Monthly Discharge of Ottawa River at Chaudière Falls, Ottawa, for 1910.

Months	Max.	Min.	Mean
January	28,000	21,500	24,750
February	22,000	16,000	19,000
March	46,500	15,500	31,000
April	73,000	47,500	60,000
May	76,000	61,000	68,500
June	70,000	45,000	57,500
July	44,500	23,000	33,700
August	28,000	22,500	25,200
September	29,000	21,000	25,000
October	33,000	20,000	25,200
November	39,000	32,000	35,000
December	39,000	22,000	30,000

Conduct of Investigation.—To secure the analytical data necessary, two trips were made down the Ottawa River, from Pembroke to Montreal. The first trip was made during June, 1910, when the flow of the river was near its maximum, and the last trip was made during October, 1910, when the river was in its low stage. During these two trips the important municipalities were visited and information secured in regard to their sanitary improvements. Printed blanks were also sent out to the towns bordering the Ottawa River requesting information of a general character in regard to population, water works, and sewerage systems. The important manufacturing concerns discharging liquid waste into the river, were visited, and a rough estimate obtained as to the amount of waste discharged by these plants.

A bacteriological field outfit was taken along on the two trips made, the 20° C. Agar plates were put up soon after collection, thus insuring a much more accurate count than could be obtained had this work been done in the Laboratory. The work was done as prescribed in the standard methods of the A.P.H.A.

The remainder of the bacteriological work was done in the laboratory together with the necessary chemical work. The chemical work was limited to a determination of the physical and mineral characteristics of Ottawa River water, because it was realized that the polluting factors would not be gross, and that the bacteriological analyses would offer a more accurate gauge as to their presence or absence.

Table No. 2.—Approximate Discharge of the Ottawa River and its Tributaries at High and Low Periods.

Information was secured regarding the quality of public water supplies taken from the Ottawa River, especially in those places where local conditions play an important part as to the sanitary quality of the supply.

Considerable interest was shown by the municipal officials, after the purpose of the survey was explained to them, and the work was greatly benefitted by their co-operation.

Population statistics have been based on local estimates and will probably be found nearly correct. The census of 1911 will be at hand soon so that slight corrections can be made where found necessary.

Vital statistics have been obtained in the most part from the Ontario Board of Health and from the Quebec Board of Health. In the case of some of the larger cities typhoid fever statistics have been secured from the local Boards of Health.

Data as to water consumption are based on local estimates, and as a majority of the supplies are unmetered, it is very probable that in some cases these estimates are not very accurate.

The Ottawa River.—The Ottawa River has its source in lakes near the height of land. The river has a length of 700 miles and has a total watershed area of 56,000 square miles. The upper part of the Ottawa flows through a granite plateau of precambrian formation, and the country is low and marshy. Below this granite plateau the river falls rapidly. The upper Ottawa basin contains many lakes having a total area of several hundred square miles. From Pembroke to Ottawa the river is a series of lakes separated by rapids.

Allumette Lake has an area of 60 square miles, Coulonge Lake 25 square miles, Lac des Chats 40 square miles and Lake Deschenes 45 square miles. The river falls rapidly at Ottawa and below this point there is 60 miles of navigable water, reaching to Grenville. From Grenville to Carillon the river falls 50 feet and then enters the Lake of Two Mountains, a large lake having an area of 75 square miles. At the foot of the Lake of Two Mountains the river divides, the major portion flowing to the north of the Island of Montreal, the remainder entering the St. Lawrence River at St. Anne de Bellevue.

Table No. 3.—Water Supplies from Ottawa River.

City or Village	Estimated Population	Estimated Population using water	Average daily consumption (gallons)	Reservoirs Capacity
Pembroke	5,500	4700	600,000	150,000
Arnprior	4,500	700	32,000	85,000
Aylmer	3,100	2600	150,000	60,000
Hull	16,700	16000	3,500,000	
Ottawa	86,100	86100	15,600,000	
Rockland	3,029	2000	50,000	
Hawkesbury	4,300	4000	300,000	
Lachine	10,350	10150	2,500,000	
Westmount	15,000	15000	1,500,000	7,000,000
Verdun	12,500	12250	425,000	
Montreal	455,800	450000	39,000,000	37,000,000

Many tributaries enter the Ottawa River, a list of which is given in Table No. 2 together with their maximum and minimum discharge. The urban population on these tributaries is scant and in only a few cases do municipalities exist which discharge domestic sewage into the rivers.

Population of Watershed.—The total population of the Ottawa River watershed is estimated between 475,000 and 500,000. Within a radius of ten miles at Ottawa, are the municipalities of Aylmer, Hull and Ottawa, having a total population of over 100,000. As only about 20,000 of the remaining population of the main river have sewer outlets into the Ottawa River, it is evident that the great percentage of the urban pollution occurs at Ottawa and vicinity.

From the flow data, secured in the Georgian Bay Ship Canal Survey Report for the Ottawa River, at Ottawa, a maximum flow of 76,000 cubic feet per second is recorded for May, 1910. When compared with the combined population for Ottawa and vicinity, the flow of the stream is about 760 cubic feet per second for each 1,000 of population. When the same comparison is made for the minimum discharge it is noted that the stream flow is 150 cubic feet per second for each 1,000 of population or one-fifth of the maximum flow. Other conditions being nearly the same it is expected that the pollution below Ottawa would reach its maximum during low water stages, when the sewage would receive less dilution than at other times in the year

Industrial Development.—The principal industries on the Ottawa River basin are lumbering and agriculture. At several points on the Ottawa River lumber mills exist which formerly disposed of their sawdust waste into the river. The chief manufacturing plants are for the manufacture of pulp, paper, sulphite and matches. The combined waste from these several plants is very small when compared to the volume of flow in the river.

Domestic Water Supply.—In Table No. 3 is listed information in repard to the water supplies of eleven municipalities on the Ottawa River which receive their domestic water supply from the Ottawa River.

In four of the municipalities, namely, Pembroke, Ottawa, Westmount and Montreal, the river water is purified by means of Calcium hypochlorite. At Verdun the water is filtered by means of a mechanical pressure filter.

It is of interest to note that in several cases the municipalities which have the most polluted water supplies and the highest typhoid death rate have done nothing as yet to improve the quality of their water supplies.

Domestic Sewage.—In Table No. 4 is shown summarized data in regard to the sewerage conditions for ten municipalities on the Ottawa River. This data shows distances below Pembroke, estimated population, estimated population connected to municipal sewers, miles of sewers, and number of sewer outlets into the Ottawa River and other local streams.

It is to be noted that the sewage from a population of nearly 500,000, which is included in this table, does not discharge into the Ottawa River, but into the St. Lawrence River, a portion of which is made up of Ottawa River water.

Manufacturing Waste.—The principal manufacturing waste on the Ottawa River is the bark from the logs. The bark becomes loosened from the log from lying in the water and falls off. A portion of the high color content of the Ottawa River water is no doubt due to the tannin extracted from water soaked bark.

At Ottawa and Hawkesbury the wash water from the pulp and paper mills enter the river. Save-alls are located on these discharge lines and prevent a large percentage of the pulp from gaining access to the river. The total amount of this waste is probably not more than fifteen to twenty million gallons daily. The sulphite liquors from the sulphite mill at Ottawa also discharge into the river. At present the amount of manufacturing waste discharged into the Ottawa River is comparatively small and does not appreciably affect the river, nor does it cause any local nuisances.

Table No. 4.—Sewerage Table for Municipalities on Ottawa River.

City or Village	Miles below Pembroke	Estimated population	Estimated population connected to sewers	Miles of Sewers: Sanitary or combined	Miles of Sewers: Storm	Number of sewer outlets Ottawa in River: Sanitary or combined	Number of sewer outlets Ottawa in River: Storm	No outlets in local streams: Sanitary or combined	No outlets in local streams: Storm
Pembroke	0	5,500	2,500	9.12	4.2	4	5	1	5
Arnpriot	69	4,500	150	4.				2	
Aylmer	97	3,100	800	4.5		1

Hawkesbury	166	4,300	4,000	4.		2			
Lachine[a]	219	10,350	10,150	14.2				1a	
Wertmounnt [b]	224	15,000	15,000					b	
Verdun	224	12,500	11,000	8.				1	
Montreal.	223	4 5,800		315				13	

[a] Lachine sewage is discharged in the River St. Pierre which later discharges into St. Lawrence River below Verdun.

[b] Westmount sewage is discharged into Montreal sewers.

Formerly when sawdust was discharged into the river considerable trouble was caused by the formation of huge banks of sawdust.

The river a few miles below Ottawa contains large deposits of sawdust, and large amounts of gas are frequently seen bubbling to the surface. The sawdust undoubtedly undergoes a slow decomposition accompanied by the formation of gas.

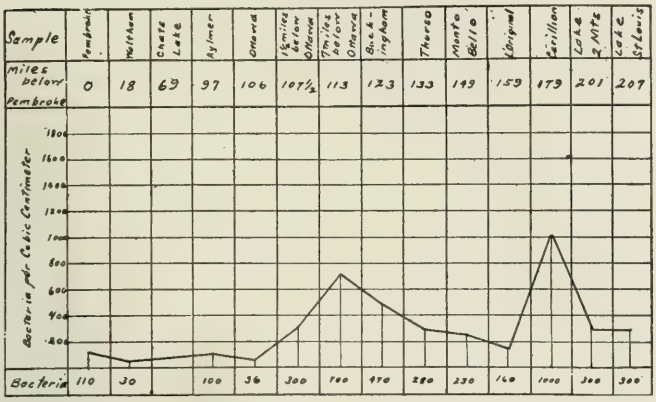
The Dominion amendment of 1895 prohibiting the disposal of sawdust in the rivers came into effect in 1899 and since that time no more of this waste has been disposed of in the Ottawa River.

Character of Ottawa River Water.—For this report, information in regard to the amount of pollution which enters

the river and the effect such pollution has on the public water supplies, has been taken from previous reports and from the analytical data recently collected by this board.

The previous reports consulted are "A Biological Analysis of the Montreal Water Supply during the periods from November, 1890, to November, 1891, by Wyatt Johnston, M.D., appearing in the Montreal Medical Journal of 1894, and "The Bacteriological Analyses of Ottawa River water," by Harrison and Vanderleck.

Figure No. 1.—Showing Bacterial Content of Ottawa River for June, 1910.



Analytical data has also been secured in connection with the Pembroke, Verdun and Montreal water supplies, particularly in connection with the water purification plants.

The work of Dr. Johnston, done in 1891, on the Ottawa River from Ottawa to Montreal, is of great value for comparing the condition of the river at that time with present conditions.

The Ottawa River from Pembroke to Ottawa receives the domestic sewage from a combined population of not over 15,000.

The municipalities discharging sewage into the river between these two points are well separated, and the nature of the river makes purification by natural agencies nearly ideal.

The germ content of the river above Ottawa is comparatively low, except where polluted for a short distance by local sewers.

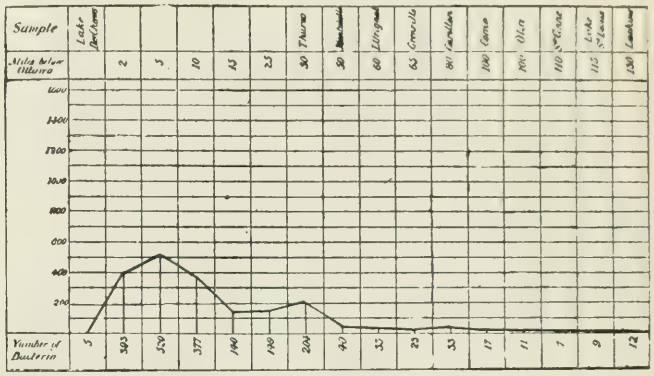
Figure No. 2.—Showing Bacterial Content of Ottawa River for October, 1910.

In most cases B. Coli is absent in one cubic centimeter which shows a rather high degree of bacterial purity for a river water.

Severe typhoid epidemics have occurred at Pembroke, Hull and Ottawa due to infection of the municipal water supplies, but this infection has always been of a local nature, that is, the municipality has infected its own water supply.

Below Ottawa the germ content of the river increases perceptibly, due to the large amount of sewage that enters the river at Ottawa and vicinity. This increase is present all the way to the Lake of Two Mountains, and is much higher during low water than when the river is near its maximum discharge, showing that the amount of dilution is the factor most affecting the germ content of the river from Ottawa to the Lake of Two Mountains.

Figure No. 3.—Showing Bacterial Content of Ottawa River for July, 1891.
(Dr. Wyatt Johnston.)

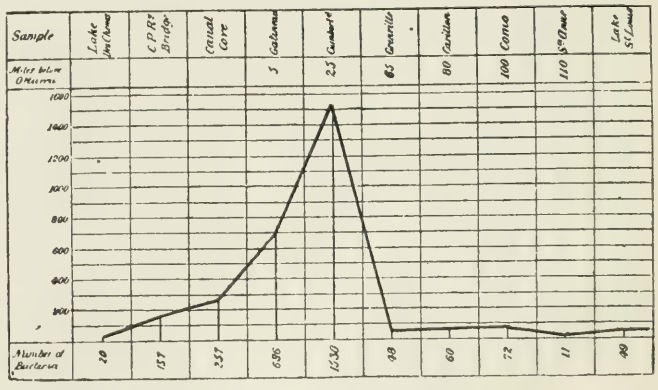


The Lake of Two Mountains acts as a natural settling basin and a decided decrease in germ content is noted after the river water has passed through this lake.

Comparative data of considerable interest is afforded in comparing the results collected by Dr. Johnston in 1891 with those collected by the Provincial Board of Health in 1910.

Dr. Johnston used alkaline gelatine plates incubated at 20° C. The period of incubation is not mentioned in his paper, but was probably not more than 48 to 72 hours, because after that period liquifying bacteria would have destroyed his plates. It will be noted that the results secured by Dr. Johnston are lower than those secured by the Provincial Board of Health. In 1891 Ottawa had a population of 37,300 and Hull 11,300, which is less than half the population of these two cities at present. The results of Dr. Johnston's work on the Ottawa River are shown in Figs. Nos. 3 and 4.

Figure No. 4.—Showing Bacterial Content of Ottawa River for September, 1891.
(Dr. Wyatt Johnston.)

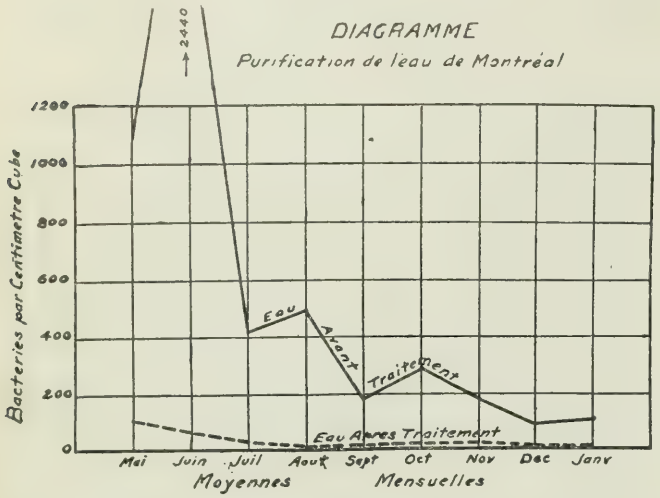


The increased germ content of the Ottawa River below Ottawa is no doubt due to the increased population at Ottawa and vicinity and to the fact that several municipalities below Ottawa now discharge domestic sewage into the river.

On the two trips made by officers of the Provincial Board of Health an increased germ content was noted below Carillon. This increase is probably due to pollution which comes from the lock chambers, as no other source can be found to account for the increase.

The analytical results secured by the Provincial Board of Health are shown in Figs. Nos. 1 and 2.

Fig. No. 5.



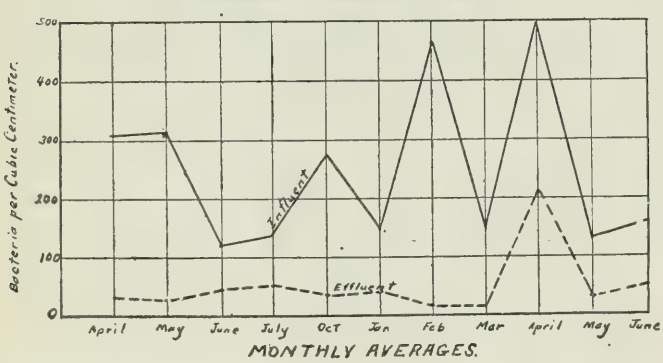
Purification of Ottawa River Water.—The Ottawa River water is being purified at Pembroke, Ottawa and Montreal by means of Calcium hypochlorite, and at Verdun by filtration through mechanical pressure filters.

The disinfection plants are only temporary in character and have been installed to treat the water only until more permanent works are constructed.

The disinfection of the Montreal supply has tended to materially reduce the typhoid fever rate and the results at the other two municipalities have been equally satisfactory.

The city of Montreal is at present constructing a water filtration plant, of the double filtration type, the city of

Figure No. 6.—Bacterial Results Secured at Verdun by Mechanical Pressure Filters.



Ottawa has had its waterworks situation investigated by Mr. Allen Hazen, who has reported on a supply either from McGregor Lake or a filtered water supply from the Ottawa River, and Pembroke has extended its water intake 7,000 feet to take water from mid-stream, thus escaping the eddies which were held responsible for the severe epidemic of 1909.

Fig. No. 5 shows the results secured at Montreal by Calcium hypochlorite sterilization, and Fig. No. 6 shows the results secured at Verdun by filtration.

Typhoid Fever Statistics.—Tables Nos. 5 and 6 shows the typhoid fever mortality at Montreal and Ottawa from 1905 to 1910 inclusive.

The Ottawa statistics appear larger than they should because non-residents who die from the disease in Ottawa are included in the mortality statistics.

Table No. 5.—Deaths from Typhoid Fever at Montreal 1905-1910.

Months	1905	1906	1907	1908	1909	1910
January	8	18	19	12	43	78
February	6	14	6	12	9	29
March	3	13	7	6	12	6
April	2	4	10	7	7	4

December	6	18	9	19	52	7
Total	55	130	122	126	212	192
Death rate per 100,000	14 6	37.	33.2	33.	53.6	42.
Estimated population	303,600	350,500	366,915	380,000	395,000	455,86

Table No. 7 shows the total death rate together with the typhoid death rate for eleven municipalities on the Ottawa River for the year 1910.

Conclusions.—This study has shown that the Ottawa River above the city of Ottawa is in a very satisfactory condition as regards bacterial purity, except where polluted for a short distance by municipal sewers. It is not probable that the amount of pollution for this district will increase perceptibly for a considerable period of time.

Table No. 6.—Deaths from Typhoid Fever at Ottawa, 1905-1910.

Months	1905	1906	1907	1908	1909	1910
January	1	1	7	0	2	2
February	2	0	4	0	11	3
March	1	2	3	0	1	2
April	0	1	3	1	1	1
May	2	1	2	0	0	0
June	1	0	1	1	1	1
July	1	0	0	2	1	1
August	1	0	2	1	0	2
September	1	2	3	1	5	3
October	0	4	4	7	2	7
November	2	0	4	2	9	1
December	1	2	3	6	2	2
Total	13	13	36	21	25	25
Estimated population	65,500	67,572	69,715	80,284	83,360	86,186
Death rate per 100,000	20.	19.2	51.6	26 1	30.	29

The work done has shown that the sewage of Ottawa and Hull pollutes the Ottawa River for a considerable distance below these municipalities. The Ottawa River from Ottawa to St. Anne de Bellevue is not fit to use in its raw state as a domestic water supply.

Table No. 7.

City or village	Miles below Pembroke	Population	Deaths in 1910		Deaths per 100.000	
			Total	Typhoid	Total	Typhoid
Pembroke	0	6000	90	2	1500	33.3
Arnprior	74	4300	53	1	1229	22.7
Aylmer	103	3000	56	1	1860	33.

Westmount	235	15000	93	3	620	20
Montreal	235	455800	10211	192	2240	42

Because of the high color content of the Ottawa River water, mechanical filtration will be found to be the most satisfactory method to be adopted to secure a purified water of satisfactory physical appearance and bacterial purity.

A portion at least of the pollution which enters the river at Ottawa and Hull should be removed so as to lighten the load on the smaller municipalities located below on the river, which will soon be forced to consider the purification of their municipal water supplies.

The amount of manufacturing waste which now enters the river causes no appreciable nuisance, and it is not at all probable that this waste will so increase as to be a polluting factor.

The construction of the proposed Georgian Bay Ship Canal will have a considerable effect on the Ottawa River. In some cases additional pollution will enter the river, but the probable biggest factor will be the equalizing of the flow of the river, which will tend to prevent the maximum pollution which occurs during the low stages of the river.

The Ottawa River, being an interprovincial stream, is outside of the jurisdiction of either province.

This condition suggests federal authority and sanitary control over such streams and bodies of water as do not lie entirely within the confines of one province.

WAVE IMPACT ON ENGINEERING STRUCTURES.

It is a well-known fact that the impact of a wave on the face or top of a breakwater formed of blocks of masonry or concrete may cause such a block to start from its seat in the opposite direction to that of impact, and may actually cause its withdrawal from the face or top of the breakwater. Cases in which blocks weighing several tons and carrying the weight of several superposed courses have been withdrawn in this manner are of comparatively frequent occurrence. The explanations of this phenomenon which have been current in the past attribute it either to the fact that the wave pressure on the face of the breakwater at the instant of impact is transmitted hydrostatically, as in an hydraulic press, to every portion of the interior, thus giving rise to an excess outward pressure at those portions of the face over which the wave is not the instant breaking, or to the compression of the air which is entrapped in the open joints. Such a compression gives rise to an internal pressure, which is maintained for some small but finite interval of time after the recession of the wave has relieved the pressure on the face. An experimental investigation recently carried out by members of the Engineering Department of University College, Dundee, and published in the Proceedings of the Institution of Civil Engineers, indicates that, assuming a maximum velocity of wave impact of 80-ft. per second, the maximum internal pressure to be anticipated on the first of these assumptions is about 2.9 tons per sq. ft., while, assuming air compression, the pressure may amount to about six tons per sq. ft. The experiments, however, point to the fact that in favorable circumstances the impact of the wave on an open joint gives rise to a "water hammer" action, analogous to that following the sudden closure of a valve at the open end of a long pipe line conveying water. Where this action occurs, pressures vastly in excess of those possible either by simple hydrostatic transmission of pressure or by air compression, are produced, and, with the assumed velocity of impact, they may amount to some 40 tons per sq. ft., or even more in specially favorable cases. The results suggest the advisability of providing a free outlet, by means of a series of drains or weed-holes opening on its sheltered face, for such water as may percolate to the interior of such a structure. Such drains, preventing the accumulation of internal water, would be an effective guard against the production of internal pressures of sufficient magnitude to affect the stability of the structure, whether due to air compression or to water hammer.

THE PREVENTION OF SMOKE.

The sight of black, thick smoke emerging from the smoke stacks of industrial plants at once inspires a feeling of prosperity and plenty. Seen from some distance this does not cause inconvenience, but at closer range it becomes obvious that it is not only inconvenient but disagreeable in the extreme, so much so, in fact, that legislation has been brought about in many municipalities to reduce what is commonly called "the smoke nuisance."

It took considerable time to educate large fuel consumers to the fact that the greater portion of the smoke going out to polute the atmosphere was really waste heat, and could be employed to great advantage in their own boilers, but within the last few years there has been a remarkable development in the utilization of coal under the steam boiler, and to-day many steam plants are burning bituminous coals practically without smoke. This is largely due to improvements in the design of the furnaces and more care on the part of the firemen.

Within the last few years there has been a remarkable development in the utilization of coal under the steam boiler. To-day many steam power plants in the United States are burning bituminous coal practically without smoke. This has been brought about by improving the design of the furnaces and by careful attention on the part of the firemen.

It is now possible to design and operate boiler plants burning a high-volatile coal which will be practically smokeless under usual operating conditions, giving off no black or dense gray smoke except when a fresh fire is being built. Banking the fire, shutting dampers, etc., cause smoke of a light or gray shade only. This has been demonstrated at the engineering experiment station of the University of Illinois, where a boiler has been installed, properly equipped with a furnace for burning Illinois coal. Under ordinary conditions this plant makes no smoke whatever. This equipment is not suitable for burning low-volatile coals such as are largely used in the East. In experimenting with this furnace an effort was made to produce smoke, but it was found impossible to make black smoke, the worst being about 50 per cent. black.

Coal can be burned smokelessly, the same as gas, gasoline, or kerosene oil, if the equipment is properly designed and adjusted. Each of these fuels will give off smoke if conditions are not favorable. All the authorities on the subject of combustion and smoke prevention agree upon the following conditions as requirements for a smokeless furnace:—

1. The coal should be supplied to the furnace in small quantities at frequent intervals. The more nearly the feed approaches a continuous and uniform supply the better the results.

2. The air supply should be slightly in excess of the theoretical amount required and be admitted principally through the fuel bed, with an auxiliary supply admitted at the front or rear of the furnace to burn gases from the coal.

3. The temperature in the furnace should be sufficiently high to ignite the gases given off from the fuel bed.

4. There should be a fire-brick combustion chamber of sufficient dimensions and so designed as to cause the thorough mixture of the gases and air, permitting complete combustion before the mixture reaches the boiler surfaces.

It has been found in this country, as well as in Europe, that when smoke is given off there is also a loss of carbon monoxide (CO) and other combustible gases. The loss due to the carbon which we see and call smoke is seldom more than 1 per cent., but the loss due to the escape of the combustible gases may amount to an additional 3 to 10 per cent.

It has been found that, contrary to general opinion, with extremely high temperatures more smoke is produced

and more unburned gases are lost up the stack. High temperature is of course due to a supply of air approaching the theoretical amount, and on account of the difficulty of obtaining a complete mixture of the gases and air some gas is allowed to escape unburned. (See Table 1.)

The combustible gas most frequently found in the flue gases is carbon monoxide (CO). This gas is nearly always present when the stack gives off black smoke, indicating imperfect combustion. Hydrogen and hydrocarbon gases may also be expected in connection with the CO, but on account of the difficulty of determining the small percentages of these gases they are seldom recorded, though the loss due to their escape is considerable. In confirmation of these statements, the accompanying tables are submitted. Table 1 gives a summary of the relation of smoke to unburned gases and combustion-chamber temperatures as determined from more than 200 boiler tests made at the St. Louis, U.S.A., fuel-testing plant.

Table 1.—Relation of Smoke to CO and Combustion-Chamber Temperatures.

	Per Cent. of Black Smoke.						
	0	0 to 10	10 to 20	20 to 30	30 to 40	40 to 50	50 to 60

Table 3, compiled from results obtained at the above-mentioned fuel-testing plant, shows that the losses due to the escape of CO and other combustible gases may be considerable and that they are of more importance than the gain from a corresponding increase in carbon dioxide (CO_2). It is evident that the prevention of smoke and the efficiency of the plant are very closely related.

LARGE CONTRACTS LET BY THE C. P. R. DEPARTMENT OF NATURAL RESOURCES.

A. S. Dawson, Chief Engineer of the C.P.R. Department of Natural Resources, reports the awarding of three large and important contracts in connection with the construction work in the Eastern Section of that company's Irrigation Block.

Messrs. Grant, Smith and Co., and McDonnell, of Vancouver, have been awarded a contract running into over $500,000 for the construction of a large reinforced concrete aqueduct, two miles in length, near Brooks, which will take the next two summers to complete.

Messrs. Jansey Bros., and Boomer and Hughes, of Calgary and Seattle, have been awarded a two-year contract, amounting to about $300,000 for the construction of a very large number of reinforced concrete structures on the canal system in that section of the Irrigation Block lying between Bassano and Brooks and the Bow and Red Deer Rivers.

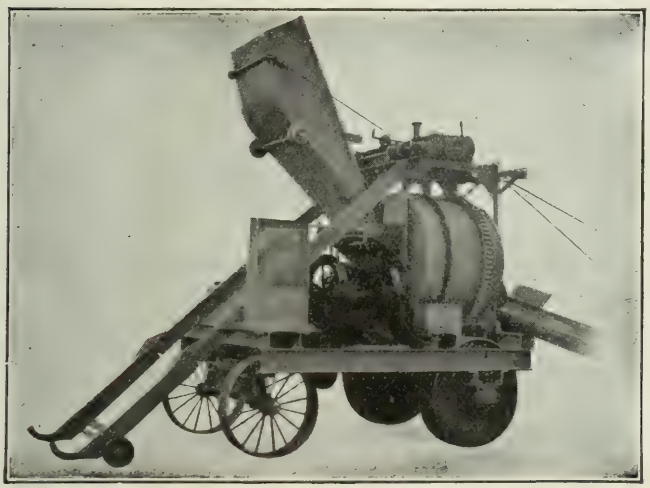
The Canada Foundry Company have also been awarded a large contract for the supplying and erection of 30 steel bridges over the main canal system, containing about a million and a half pounds of steel, which, with masonry abutments, will provide practically permanent structures.

Work on all of these contracts will be commenced in the immediate future, and several hundred men, large numbers of teams, and an elaborate construction plant will be required for their completion.

A NEW DESIGN OF STREET MIXER.

The Ransome Concrete Machinery Co., Dunellen, N.J., have just put on the market two new types of street mixers, the No. 60 and No. 61. There are many points about these which are different from anything which has been offered to date by mixer manufacturers, and the design has been made by the Ransome Company after a long study of the street paving contractor's problems. The No. 60 machine is a steam driven outfit regularly furnished with 10-foot distributing chute capable of handling 14 cubic feet of loose material, and will mix 40 to 60 batches per hour depending upon the speed which the material can be fed to the pivot hopper. The engine is 8 h.p. and the boiler 9 h.p. The machine is arranged to drive in both directions along the work.

The various levers controlling the operations of hoisting, discharging and traction are all brought to one point and the entire operation can be controlled by the engineer. The chute will swing through an arc of approximately 180° while the discharge point is 3ft. 7in. above street level. The outfit is mounted on 24 and 28-in. wheels with 10-in. tires. The net weight of the machine complete with power is approximately 11,000 lbs.



View of the No. 61 Mixer Showing Skip Discharging and Chute.

The No. 61 Ransome street mixer will handle up to 20 cubic feet of loose material and will mix from 40 to 60 batches per hour. It is regularly equipped with a 2-cylinder opposed gasoline engine and 2 20-ft. distributing chute. It is arranged with a clutch by which the drum can be thrown out and remain idle while the machine is traveling along the road, and it is also equipped with a traction device adapted for moving in either direction. A notable feature of this outfit is the fact that the over-all height has been kept within 11 ft. 2 ins. This has been done by eliminating the charging hopper and emptying direct from skip into mixer.

The driving wheels are 44-ins. in diameter and the front wheels 40-ins., the tires being 10-ins and 8-ins. respectively. By using these large wheels an 18-inch clearance above the ground has been made possible, thus avoiding any jacking up of the machine to clear manholes which are liable to project 12-ins. or more above the sub-grade of an unfinished street. When desired, flanges may be bolted to the tires, thus making the outfit suitable for operation under the machine's own power on trolley tracks, etc. If the outfit is to be drawn behind a trolley car at high speed, standard flanged wheels may be readily substituted for the ones regularly furnished, as the wheels are easily taken off inasmuch as the driving axle is mounted in split boxes and the front axle can be swung around and the wheels slipped off.

All of the operating levers have been brought adjacent to the operating platform at one side of the machine. The steering wheel is in front. The line shaft is driven by chain and the power is transmitted through clutches to the windlass for operating the hoist, the drum and the traction wheels. Of course, when desired an electric motor can be substituted for the gasoline engine, and when operated in railway service the motor could be run from overhead trolley wire. The general dimensions are as follows:

Weight	15,000 lbs.
H.P.	16
Height over-all, skip raised	14 ft.
" " exclusive of skip	11 ft. 2 ins.
Extreme width	8 ft. 6½ ins.
Length, exclusive of skip and chute	17 ft. 1 in.
Length, with skip lowered	20 ft. 10 ins.

HEAVY ELECTRIC TRACTION IN EUROPE.

At a meeting of the American Institute of Electrical Engineers held at Schenectady, N.Y., May 17, 1912, C. E. Eveleth, General Electric Company, presented a paper entitled "Some Impressions of the Electric Traction Situation in Europe." Perhaps the most fundamental difference from American practice was in the relative magnitude of the drawbar pulls required for handling either freight or passenger trains. The ordinary European drawbars were designed for normal working pulls of 12 tons to 15 tons and or a breaking strength of approximately twice these values. Some American drawbars had shown normal working values of 40 tons to 50 tons and breaking strengths of 100 tons to 150 tons. In Europe there were practically no automatic couplers, as the cars were generally coupled by links with turnbuckles. The train limitations were such that with a liberally powered locomotive not more than 60 tons could be utilized on the drivers, whereas Americans do not hesitate to couple two locomotives to secure a total weight of about 200 tons on the driving axles at the head end of the train, as in the Detroit River and the Great Northern electrifications. European locomotives with plate-frame structures were made to withstand end strains of about 30 tons. In this country the locomotives were designed for end strains of approximately two and a half times the locomotive weight. These differences naturally lead to radically different types of mechanical design. The lower tractive effort at starting demanded of European locomotives resulted in equally radical differences in the electrical design of the motors.

England.—Mr. Eveleth said that studies were being made for the electrification of the steam suburban traffic in several large cities like London, Manchester and Liverpool. Suburban electrification had been very much affected by the introduction of motor buses and the extension of surface tramways. The London, Brighton & South Coast Railway's loop from London Bridge to Victoria Station offered an interesting example of the benefits of electrification. About seven or eight years ago, when this division was operated by steam, about 8,000,000 tickets a year were sold. Owing to the development of surface transportation competition, these sales dropped to about 3,500,000 tickets per annum. However, since the single-phase electrification was completed about two years ago, the ticket sales have increased so rapidly that they are now about 9,000,000 per annum.

Mr. Eveleth thought that the general consensus of engineering public opinion in England seemed to indicate a decided preference for direct current for the English conditions. The London, Brighton & South Coast line, of course, was an exception. No operating costs on the Brighton system had been made public, and the manufacturer appeared to be still interested in the experimental development of the motors and control, so that all maintenance was not yet entirely in the hands of the railway. Several of the electrifications under consideration were being studied on the basis of 1,200 volts direct current and higher. One manufacturer had already built a 3,500-volt d.c. locomotive, energy for which was furnished by a single-commutator 3,500-volt machine.

Holland.—The great extent of the freight transportation by canal in Holland made it hardly likely that any considerable electrification of steam railroads would soon take place there. The single-phase electrification between Rotterdam, Haag and Scheveningen had been taken over by the parallel steam railroad. The schedules on this line were not severe, and the service called for an average of about one stop in 10 miles. The maintenance costs were said to be rather high and no immediate extensions were contemplated.

France.—Considerable study was going on in France, but as yet there had been no large installations. The engineers of the Paris-Mediterranean-Lyons Railway had developed a locomotive which took power from a single-phase trolley and operated d.c. motors on the axles, the current for these motors being transformed by a synchronous commutator known as a permutator. In its present state this locomotive was purely experimental. The single-phase system was represented by one or two small tramway lines and by some undertakings which were being carried out by the Midi Railway. The latter company had purchased five different single-phase locomotives from as many manufacturers for experimental operation in Southern France on sections involving heavy grade haulage with regenerative braking. Up to March, 1912, three locomotives had been delivered. The electrifications were being carried out under government subsidies, without which they would hardly be justified, as there was little traffic. Several of the lines to be operated electrically had not yet been built, and it would probably be several years before the locomotives were in active operation. The 2400-volt, three-wire d.c. system at Mure was now being extended with a trolley having 2,400 volts between the overhead conductor and the track. The most serious undertakings contemplated in France were those connected with the electrification of the steam railroads at Paris, although the State Railways and the Paris-Orleans Railway contemplated the extension of their electric suburban lines with the d.c. third rail. Mr. Eveleth found that the engineers of the French State Railways believed that the direct current was cheapest in first cost and operation for any of their lines upon which electrification was desired.

Switzerland.—The Simplon tunnel three-phase electrification appeared to be successful in every way. At first great trouble was experienced from insulation breakdowns on both motors and transformers due to condensation when the cool locomotive passed into the tunnel where the temperature is about 115 deg. Fahr because of hot springs. This condensation caused every portion of the electric locomotive to be drenched with water. This trouble is now avoided by warming the locomotives over heated pits at the terminal before they enter the tunnel.

In making studies for the electrification of the St. Gotthard tunnel the engineers of the Swiss government found that the single-phase system was about 20 per cent. less in first cost than the three-phase system and about 33 per cent. less than direct current. This difference between the installation cost of direct current and single-phase was much greater than had ever been found in any analysis of conditions in the United States. Some of the fundamental assumptions of the Swiss analysis were as follows: Cost of single-phase d.c. locomotives essentially the same; each substation equipped with motor-generator sets and complete installation of spare units; each substation equipped with storage batteries; substations located half the calculated required distance apart to insure continuity of service in case of disaster to any individual station. Voltage regulation conditions were taken to be considerably better than those generally adopted in America. It was estimated that the direct-current and single-phase locomotives would have essentially the same maintenance costs, and that these costs would be about one-half of those required for steam locomotive upkeep.

Italy.—The most important electrifications in Italy were the three-phase installations by the government at Valtellina, Mount Cenis and the Giovi tunnel near Genoa. Electric traction applications in Italy had been made on mountain grades and those contemplated in the immediate future involved similar conditions. The work had proved entirely satisfactory to the government both as regards installation and operating costs. The extensions now contemplated would involve the purchase of several hundred locomotives within the next two years. The electric locomotives on the Genoa division would soon haul about 15,000 freight cars a day, thus making it the heaviest section of electric traction on the Continent. A most extraordinary and perhaps unexpected saving had been found in the reduction of rail wear. When the Giovi tunnel was operated entirely by steam the up-grade rail lasted about twelve years and the down-grade rails about three and one-half years. Apparently the restricted axle movement with brakes on the descending steam train resulted in a scouring action on the railheads. At any time during steam operation fresh deposits of metallic dust from the rails and brakeshoes were to be seen on the ballast. Electric service for one and a half years indicated that the down-grade rail would last as long as those on the up-grade tracks. This saving of practically two sets of rails in twelve years was equivalent to approximately the total interest on the power plant and transmission system. Allowance was now being made by the Italian engineers for this factor in making electrification studies for tunnel conditions similar to those at Genoa. Mr. Eveleth thought that this character of saving had not been recognized in America, probably due to the fact that practically all American tunnels with grades are single track, and the difference of wear between the ascending and descending track with the steam service had not been recognized.

Regeneration had also affected a saving of 17 per cent. in coal. When the entire division was electrified the possible saving in coal would be much higher. The difference in the energy represented by the present saving and the anticipated saving was now wasted in the water rheostats at the power house, which were adjusted to dissipate energy in excess of that which could be utilized by ascending trains. The Italian engineers were enthusiastic over the three-phase system for their conditions, and the results obtained certainly warranted their enthusiasm.

Germany.—The most important developments in Germany were in connection with the state railroads. The government engineers believed in the economic advantage of electrification which permitted the use of inferior grades of brown coal which were not fit for ordinary locomotive service.

Up to the present time all of their work had been of an experimental character, but this had been combined with the commercial operation of the Hamburg-Blankenese-Ohlsdorf line, on which multiple-unit motor-car trains were used.

Referring to the Dessau-Bitterfeld locomotives, Mr. Eveleth found it interesting that the tendency in Germany was to make a single motor do as much as possible by coupling it to several driving wheels, while in the United States the tendency was to have a multiplicity of small, higher-speed motors connected in some way to the wheels through gearing. About six years ago the German government engineers had decided upon the standardization of single-phase in the belief that it was best adapted to German conditions, which required uniformity, chiefly for military reasons. The relative amounts of operating expenses compared with other systems had apparently not been investigated. All of the principal German manufacturers were now taking very active interest in the development of d.c. equipment for 1,000 volts and more. There were a dozen or more gas-electric cars in passenger service on the Russian frontier and it was understood that about 100 more were soon to be built.

Sweden.—The experimental lines built in Sweden some years ago had been dismantled, but the government had recently contracted for the equipment of one of its Lapland lines to transport iron ore from Kiruna to Riksgränsen. The Swedish engineers were also engaged in the development of gasoline-electric and Diesel electric car equipments for general use throughout the kingdom.

ON THE IMPOUNDING OF WATERS TO PREVENT FLOODS.

By A. H. Purdue.

The recent disastrous floods of the Mississippi have impressed anew upon the mind of the public the necessity of adopting all possible measures to prevent the recurrence of such in the future, and if this can not be done, to reduce the effects to the minimum. The subject was discussed at the Southern Commercial Congress, which met in Nashville from the 8th to the 10th of last April, and was a natural theme at the National Drainage Congress, which convened in New Orleans from the 10th to the 13th of the same month.

At both of these congresses there were those who advocated from the platform the impounding of the headwaters of the Mississippi as a solution of the flood problem. While this proposed means of controlling floods doubtless has been investigated by competent engineers, the writer is ignorant of their conclusions; but it has always seemed to him that such is impossible, and on account of the great cost, impracticable were it possible. For his own satisfaction, he indulged in a little investigation relating to the distribution of the rainfall that supplies the flood waters of the Mississippi, the results of which are given later in this article.

Any consideration to determine the feasibility of controlling floods must take into consideration what becomes of the rain that falls upon the earth, for this is the source of flood waters, as of all the waters upon the land. A part of the rainfall evaporates, a part soaks into the ground, and a part runs off over the surface.

The amount that evaporates varies with the dryness and the temperature of the atmosphere. In arid regions, this is always great—so great that much of the rainfall disappears before it reaches the ground. In humid regions, it is great in summer, when the air is both dry and warm; and small in winter and spring, when the air is moist and cold. The amount that soaks into the ground varies with a great many things, among which are the rate of the rainfall, the steepness of the slope, the vegetation of the surface, the amount of water in the ground, and whether or not the ground is frozen.

If the rain falls rapidly, a much smaller amount enters the ground than if it falls slowly. In running over steep slopes, much less enters the ground than if the slopes are flat. If the surface contains little or no vegetation, much less water will enter the ground than if it be covered with grass or forests. If the ground is frozen, but little or no water can enter it. If the ground is full of water, no water can enter, and it must all run off. The last named condition probably is more important in considering the causes of floods of large streams than any other, though it is the one most commonly overlooked.

The part that evaporates has nothing to do with floods or with stream flow. The part that enters the ground is the source of supply for springs, seeps, growing crops, forests, etc. This is the only supply of streams in times of drought. The part that runs off is the cause of floods.

Those who favor the impounding of waters to prevent floods reason as follows: The Mississippi gets its chief supply of water from the Ohio and Missouri. The supply of the Ohio comes from the Appalachian Mountains and that of the Missouri from the Rocky Mountains. If the supply of these two streams were dammed up in the numerous deep ravines and valleys through which it flows in their upper courses there could be no flood.

So far as it goes, this is all right. The large run-off in these parts does cause floods in those parts. But it is a mistake to suppose that these waters are the only source, or even the main source, of supply of the flood waters of the Ohio and Mississippi. The Ohio drains West Virginia, most of Tennessee, a part of Illinois, most of Indiana and Ohio, and part of Pennsylvania; and the Missouri River drains a large part of the eight states along its course. Besides, there flow into the Mississippi a large part of the waters of Illinois, Wisconsin and Minnesota. In fact, the headwaters of the Ohio and Missouri, which streams are the chief source of supply for the Mississippi floods, are only a small fraction of the supply of those streams. Most of their waters are received along their courses after they leave their mountainous headwater areas.

The effect of the great area of the central states upon floods is overlooked by those who advocate impounding to prevent floods along the Mississippi, because it is supposed that their generally flat surface causes most of the water to soak into the ground. But it must be remembered that after the ground is frozen or is full of water no more can enter, and what falls must run off. It is during the seasons of general and prolonged rains over the Mississippi Valley that the floods occur. After the ground becomes saturated with water, the rainfall of this great central area must at once find its way through the numerous streams that finally converge into the Mississippi. If the Ohio and the Missouri are in flood separately, the lower Mississippi can carry off the waters without overflowing. The disastrous floods come when these two rivers and the upper Mississippi are discharging large volumes of water at the same time. If it so happens, as is usually the case, that Arkansas and Red Rivers are then in flood the waters from these check the flow of the lower Mississippi and cause the accumulation of water between their mouths and the mouth of the Ohio.

To ascertain where the water comes from that causes the Mississippi floods, the following table has been prepared. The rainfall over the area that supplies the flood waters is

taken for the months of February, March and April, as it is this water that usually produces the floods.*

Table of the Average Precipitation and Volume of Rainfall for the Months of February, March and April Over the Flood Supplying Portion of the Mississippi Basin.

STATE	Months Feb.	Mar.	Apr.	Total	Area	Per cent. drained into Miss. River	Billion cubic yds. drained into Miss R.
Montana	0.78	1.21	1.28	3.27	145,310	90[2]	36.80
Wyoming	0.83	1.49	1.46	3.78	103,645	75[2]	25.27
North Dakota	0.56	1.03	1.58	3.17	70,195	66[2]	12.63
South Dakota	0.48	1.27	2.10	3.85	76,850	100	25.44
Nebraska	0.72	1.11	2.61	4.44	76,840	100	29.34
Kansas	0.99	1.45	2.59	5.03	81,700	100	35.34
Oklahoma	0.74	2.20	2.68	5.80	70,430	100	35.13
Minnesota	0.71	1.40	2.15	4.26	79,205	66[2]	19.15
Wisconsin	1.13	1.98	2.44	5.55	54,450	75[2]	19.49
Iowa	1.06	1.92	2.83	5.85	55,475	100	27.91
Illinois	2.37	3.18	3.30	8.85	56,000	100	42.62
Indiana	2.89	3.85	3.11	9.85	35,910	93[2]	28.29
Missouri	2.29	3.57	3.62	9.48	68,735	100	56.04
Arkansas	3.55	5.22	4.18	12.95	53,045	100	59.08
Pennsylvania	3.02	3.75	3.03	9.80	44.985	25[2]	9.48
Ohio	2.60	3.50	2.87	8.97	40,760	75[2]	23.58
West Virginia	3.06	4.29	3.75	11.10	24,645	100	23.52
Kentucky	3.57	5.24	3.46	12.27	40,000	100	42.21
Tennessee	4.72	5.24	4.24	14.20	41,750	100	50.98
Colorado	1.03	1.02	2.01	4.06	108,645	33[2]	12.52
Total					1,328,575		614.82

It will be seen from the table that the volume of the average rainfall of the area for the three months is 614.82 billion cubic yards. This is equal to 112,774 cubic miles, and would cover the states of Ohio, Indiana and Illinois to the depth of 4,488 feet. This, it must be remembered, is the volume of the average rainfall. In seasons of unusual rainfall, like the past spring, the volume is of course much greater. It must be disposed of by running off, by soaking into the ground, and by evaporation. As the evaporation at this season of the year is small, most of the water must be disposed of by the other two processes; and as the ground is full or nearly full of water, or is frozen, over a large part of the area named, an unusual per cent. of the enormous volume disappears as run-off. It is this that produces the floods. If half of it is run-off, this would cover the three states named to the depth of 2,288 feet, when the rainfall for the three months named is normal. The Mississippi River Commission doubtless know how much water the Mississippi can discharge within a given time without flooding. The difference between this and the volume of the run-off is what would have to be impounded to prevent floods.

No attempt was made to approximate the entire area over which the headwaters of the Mississippi might be impounded, for without surveys such would be little more than a guess; but in order to get at some idea of the possible effectiveness of impounding, it is estimated that the water over 30,000 square miles about the head of the Ohio can in part be put under such control. This is thought to be a very liberal estimate. The area and volume that could be impounded in Wyoming and Montana was not estimated, but it will be noticed by reference to the table that the total rainfall in these states, for the three months named, is small.

The volume of the rainfall over the area taken about the headwaters of the Ohio for the three months named, is approximately 26.96 billion cubic yards, or only 4.37 per cent. of that over the entire area that supplies flood waters to the Mississippi. It will be seen that even though all this disappeared as run-off, and could all be impounded, the effect upon the floods of the Mississippi would be insignificant. But a part of it soaks into the ground, and a part evaporates. The amount that could be impounded would probably be only a small per cent. of the remainder, or the run-off, for with the steep gradient of the streams, the reservoirs would soon fill and overflow. The floods would be reduced only by the small per cent. that they could hold. To accurately determine this, would require careful surveys.

Probably the headwaters of the Ohio and other streams can be so impounded as to avoid disastrous floods in these parts, and at the same time furnish a large amount of needed water power. The contention here made is that it seems impracticable to so impound the water of the Mississippi Basin as to prevent the disastrous floods of that stream. The only known means of controlling this water in times of prolonged and general rains is by levees; and for these to be made reliable, they will have to be strengthened by the use of concrete, or by other means. This would be an enormous and expensive undertaking, but the great Mississippi never can be subjugated without an outlay of many millions.

*The average rainfall for the states and months named was supplied by Mr. Roscoe Nunn, of the U.S. Weather Bureau, Nashville, Tenn.

[1]The computations were made by A. R. Dismukes, Assistant Instructor in Surveying, Vanderbilt University.

[2]Approximated.

RADIUM.

The infrequency of deposits of uranium ores and the ever-growing demand for its product—radium—has enhanced the price of the latter to an almost prohibitive point. Though the most important accumulations of pitchblende are worked at Joachimsthal, in Bohemia, there are many other countries in which radio-active minerals exist. In Cornwall pitchblende occurs in many tin veins with uranite and bismuth; in St. Stephen's are two lodes intersecting clay slates, which have yielded large quantities of pitchblende and uranite; chalcolite, a phosphate of uranium and copper, of an emerald green color, has been met with in beautiful crystals at Gunnis Lake, Tincroft, and other mines. Pitchblende has been found also at Rezbanya, in Hungary, and near Adrianople. Small veins of uranium phosphate occur in Portugal and at Autun. Copper uranite occurs in the mines of Saxony.

The discoveries of carnotite, also a phosphate of uranium, near Olary, 200 miles northwest of Adelaide, on the Broken Hill Railway, have been prominent. From Radium Hill 30 tons have been expedited to European laboratories. The reserves have been estimated at 5,600 tons, which are estimated to produce 5½ millograms of radium bromide per ton and 162,400 lbs. of uranium oxide. Works are being erected to manufacture radium, and the manager expects to have two grammes of bromide within a year, which at present price would represent $150,000. Near Mount Painter, in South Australia, is a vein over a mile in length, from which has been obtained autunite containing 30 per cent. of oxide of uranium, and six tons have been exported to Europe. Radium being so valuable, prospectors should carefully examine all unknown dark yellow or green minerals, which can be easily tested with sensitised collodion paper by placing the specimen on it and leaving it in the dark for a fortnight; the paper, after development, will be found peculiarly mottled with black spots. At the growing village of Joachimsthal a kurhaus was established in 1910, where radio-active baths are enjoyed and radio-active water drunk medicinally.

WORK OF THE COMMISSION OF CONSERVATION.

Public health, agriculture, forestry, fisheries, minerals and water-powers, in various important aspects, are dealt with in the third annual report of the Conservation Commission. Probably the most immediately interesting subjects discussed are the consolidation of the various public health services of the Dominion and the measures for the protection of forests from fire that have recently become law.

The public health section of the report states that the Dominion spends yearly the sum of $377,485 on various public health services scattered among four different departments, and shows how economy could be effected and efficiency gained by consolidating these under one public health branch. Other public health topics discussed are meat inspection, uniform vital statistics, biological laboratories for preparing vaccines and anti-toxins, and housing and town planning.

As a result of the agitation carried on by the commission ever since its inception, a law was passed last year by which railways are held responsible for damages inflicted by forest fires caused by their locomotives and are required to patrol dangerous portions of their lines during the dry season. A few weeks ago the railway commission promulgated regulations under this law. Mr. Clyde Leavitt, forester of the commission of conservation and chief fire inspector for the railway commission, is now in British Columbia to see that the regulations are carried out.

The report also contains an address by Mr. R. H. Campbell, director of the forestry branch of the department of the interior on "The New Rocky Mountains forest reserve," an area of 17,900 square miles recently set aside as a reserve largely through the efforts of the commission of conservation and the Canadian Forestry Association.

Fur farming is one of the interesting matters discussed in the section devoted to fisheries and game. Foxes are now being successfully raised for their fur in Western Ontario and in Prince Edward Island. On account of the almost prohibitive price of furs the commission has decided to issue a well-illustrated report on this industry in order that more people may be induced to engage in it. Other matters dealt with in this section are the oyster fisheries, which are in a declining condition, and the shad fisheries, the production of which has fallen off fifty per cent. in the last decade.

A detailed account of the agricultural survey being conducted in every province by the commission is given, as well as a description of the illustration farms now being started in connection with it. Not the least attractive part of this section of the report is a number of diagrams showing graphically just what progress weeds are making against the farmers of each province.

The work being done in taking stock of the water-powers of the country is given in detail, special attention being given to the Athabaska River.

That peat fuel can now be manufactured at a price to compete successfully with coal is the announcement made in the minerals section of the report. The importance of this can be realized when it is known that Canada has 37,000 square miles of peat bogs ranging from five to ten feet in thickness, and that two pounds of average air-dried peat are equal in fuel value to one pound of good hard coal. Other topics treated of in the minerals section are the briquetting of slack coal, the plugging of gas wells, and mine accidents.

WATER SOFTENING.

Some notes on Water Softening were presented by Dr. John F. Meyer to a meeting of the Institution of Municipal Engineers of England.

He remarked that in 1850 Theodor Way established the fact that natural zeolites placed in contact with salt solutions were capable of absorbing the bases contained in the dissolved salts, at the same time yielding up into solution the bases which they themselves contained; and in 1906 Professor Gans, of the Mining Academy of Berlin, took out a patent to manufacture artificial zeolites on a commercial scale, calling his product "permutit." The great outstanding property of permutit, against the natural zeolites, was its greater power of exchanging its own base against other bases.

If a water of a given hardness was passed through a bed of sodium-permutit, the sodium in the permutit was replaced by the calcium and magnesium taken from the water, giving a calcium-magnesium-permutit, while the acid radicals formerly united to the calcium and magnesium in the water united with the sodium which was turned out of the permutit. There would obviously come a time when all the sodium in the sodium-permutit had been replaced by calcium and magnesium from the treated water. When this period was reached it was not necessary to renew the permutit which had become exhausted, but to regenerate or revivify it. This was done by the action of a solution of common salt on the exhausted permutit. The laws of chemical exchange again came into play, the interchange being in this case in the opposite direction, sodium from salt driving out the calcium and magnesium from the exhausted permutit and converting it back to sodium-permutit. It was obvious that all the manufacturer of sodium-permutit plants had to do was to calculate how much sodium-permutit was necessary to take out the hardness of the water per hour and per day, and then to place the permutit into a cylinder.

Many methods had been, and still were, employed to soften water; one precipitated the lime and the magnesia in the water by addition of lime and soda, the other by addition of lime and baryta, and the third by addition of caustic soda. But they all suffered from the disadvantage that in the softening of cold water the precipitation of the lime and magnesia did not take place instantaneously, but only after a comparatively long time. It was also impossible to obtain a complete softening down to zero degrees by any one of the processes. In view of the fact that most of the water supplies in England were of a variable nature, the constituents changing daily, in some cases hourly, it was only by the aid of a fully trained water chemist that it was possible to use any of the above-mentioned processes for softening water down to 4deg. without making it more injurious than the crude water, on the one hand, through an excess of the reagents used, and, on the other hand, by an insufficient quantity of chemicals, resulting in a partially treated and invariably turbid and cloudy water. He had nothing to say against the three processes when they were worked by a trained water-chemist, who made analyses of the water every hour and adjusted the amount of reagents according to his analyses, testing at the same time the composition of his reagents and controlling the softened water. But he condemned the practice of many of those who sold a so-called automatically working lime and soda water-softening plant. The manufacturer found this automatically working apparatus could not produce automatically a soft water, because the crude water changed every day, making it necessary to add different quantities of reagents, and in many cases the automatically worked water-softening plant ended in the works as a storage tank. But the composition of the permu-

tited water was such that these troubles could not occur, because there was no lime and magnesia left in the water. The hardness of the water, however much it might vary initially, was always reduced to O deg., and therefore no incrustation could take place in economizer tubes or boilers.

TELEPHONE EARNINGS AND EXPENSES.

Considerable difficulty was experienced by Mr. J. L. Payne, statistician of the Department of Railways and Canals, Ottawa, in obtaining from rural telephone companies a statement of revenue and operating expenses, and the information under those heads is not quite complete. The requirements of the departmental schedule were neither complicated nor elaborate; yet they were in many instances misunderstood. As far as possible these omissions were adjusted by supplementary returns, and it is believed that little difficulty will be experienced hereafter in this regard.

The gross earnings reported amounted to $10,068,220.03, and the operating expenses to $6,979,045.06. The ratio of operating expenses to gross earnings was 69.32. The net earnings, or the immediate difference between gross income and expenditure for operation—without taking account of proper deductions for interest on bond liability, taxes, etc. —aggregated $3,089,174.97.

It is proposed to draw up a balance sheet for the current year, so simple in character that secretaries of the smaller companies, although unskilled in accounting methods, will not be confused by it. In dealing for the first time with the accounts submitted to the Department, it was not possible to work out a statement which would accurately show the balance available from the year's operations for dividends and betterments.

The gross earnings were equal to $33.25 per telephone, or $14.64 per mile of wire. The operating expenses were equal to $23.05 per telephone, or $10.15 per mile of wire.

Earnings and operating expenses were distributed among the provinces as follows:—

Province.	Earnings.	Operating Expenses.
Ontario	$ 473,992.88	$ 219,102.22
Quebec	6,127,055.81	4,136,083.27
Nova Scotia	415,154.34	313,854.35
New Brunswick	318,992.01	195,155.89
Alberta	439,846.10	250,707.48
Saskatchewan	279,559.29	162,348.34
Manitoba	1,123,446.62	1,032,034.36
British Columbia	856,570.72	643,438.34
P. E. Island	33,602.26	26,320.81
Total	$10,068,220.03	$6,979,045.06

It was found impracticable to make a fair analysis of earnings and operating expenses by companies. The rural systems, for example, are not conducted on a uniform basis. In some instances the method adopted was to assess each member of the organization his proportion of the operating cost for the year, and thus produce a balancing of accounts.

In others, a definite charge for telephone service was made, and the balance as between income and outgo was passed to the credit of the country. In still a considerable number of other cases, the plan followed was to build and equip the line, and pass over the work of operation to one of the major companies. For this operating service a specified charge per subscriber was imposed. The situation was increasingly complicated by the fact that in further instances the local company rented a certain wire mileage from one of the major systems, installed its own telephones, conducted its own central office, and paid for the cost of operating by charging a specific sum to each member.

PRIZE ESSAYS ON THE CREATION OF A SCIENTIFIC BODY OF MEN.

The following circular letter has been sent out to all members of the Canadian Society of Civil Engineers by Prof. C. H. McLeod, the secretary of the Society, under authority of the council. All members are invited to submit essays.

The offer of two prizes for essays on a suggested technical service for Canada, which follows, is designed to accomplish something which should be of very great service to this country. No matter how efficient Canada's representatives in Parliament may be, they cannot be expected to have the experience in technical matters that scientifically trained men possess, in working out, amongst other things, the economic as well as the engineering features in the construction of canals, the deepening of waterways and harbors, the construction of compensating works for obtaining the highest efficiency of available waters in navigable channels, the conserving and distribution of water for domestic purposes on our great western plains. These and many other problems are interrelated, and those called upon to deal with them in order to obtain the greatest efficiency should operate under one head with proper rules for the care and promotion of its members. Such a body could look after the expenditure of public moneys in connection with such works as well as decide as to the needs of the various parts of the country for public buildings, including their character and cost, features that are to a large extent settled to-day upon political considerations.

Canada has strong technical men in this service, but they are like so many loose threads. The present scheme is to work out some organization to gather up these loose threads and make them the basis of a united force, to be reinforced from time to time by some system, thereby bringing into the service of the country the very best men it produces.

In order to arouse an interest in the creation and development of a strong technical and cohesive force to be employed in the public service of Canada, two prizes have been offered—one of two hundred dollars, and the other one hundred dollars—for the two best essays on the subject above named. It is suggested that a brief outline be given of the character and growth of the engineering forces in the service of some other countries, such as Great Britain, France, Germany, and the United States. Then to follow on with an outline for the suggested development of a body of technical men for a Canadian service, which, if adopted, would give the country in time a self-contained force of highly trained scientific men competent to handle with the maximum efficiency the large problems in the development of this country.

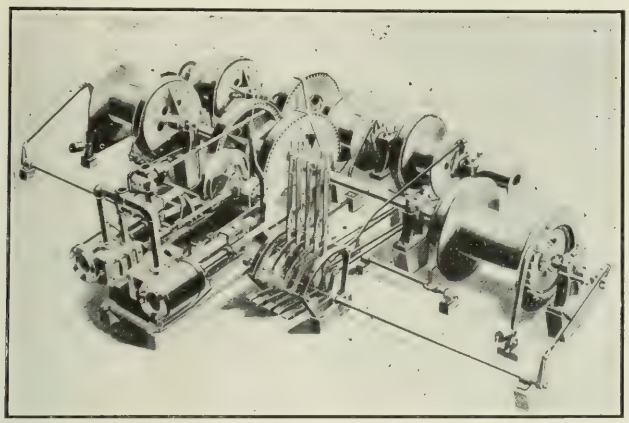
Competitors will not be limited as to length of essays. They should, however, be as concise as possible, sign with an assumed name, accompanied by the real name and address in a sealed envelope. The papers should be addressed to Lieut.-Colonel E. F. Wurtele, Quebec, P.Q., and delivered not later than August 1st next, when they will be examined by three judges whose names will be announced at a later date.

FORESTRY CONVENTION AT VICTORIA, B.C.

On the invitation of the Government of British Columbia, the next convention of the Canadian Forestry Association will be held in Victoria, B.C., September 4-6. While matters relating to Pacific Coast timber will be particularly dealt with, subjects relating to Canadian forests in general will be discussed by leading authorities. The President of the Association, Mr. John Hendry, of Vancouver, in conjunction with the Provincial authorities, is arranging the details.

LARGE ENGINE FOR DREDGE.

There has just been completed the special 10 x 12 double cylinder, 70 h.p., non-reversing engine for gravity-swing, orange-peel, dredge, illustrated in the accompanying photograph. This engine has two main drums to operate the orange-peel bucket and boom, three smaller drums for raising the spuds, and two winch-heads for shore lines. The main drum shaft is 4-7/16 inches in diameter by 28 feet in length. The spud-raising drum shaft is 3-11/16 inches in diameter by fifteen feet long, and is geared to the main drum shaft with bronze-bushed clutch, allowing the spud-raising shaft to be thrown out when not required. The main drums



View Showing Engine.

are operated by regular screw thrusts, the spud-raising drums by internal oscillating cam thrusts. All drums have brake-bands. The distance from centre to centre of the main drums is 23 feet, and the over-all distance of the engine, 30 feet. All friction heads are of cast steel; as, of course, is all gearing. The gear on the main drum shaft is 42 inches in diameter. The shipping weight of the entire engine is about 26,000 lbs. This engine was made by the Clyde Iron Works, of Duluth, Minnesota, to the special order of Doullut and Williams of New Orleans, and is a larger size of the same engine which was originally designed and made by the same Company, to the order of the Phillips Land Company.

PROGRAMME TWENTY-SECOND ANNUAL CONVENTION CANADIAN ELECTRICAL ASSOCIATION.

The annual meeting will be held at the Chateau Laurier, Ottawa, Wednesday, Thursday and Friday, June 19th, 20th and 21st, 1912.

Wednesday, June 19th.

10.00 a.m.—Opening session. Address of welcome by His Worship the Mayor, at Chateau Laurier. Minutes. President's address. Secretary-treasurer's report. Correspondence. General business.

11.30 a.m.—Report of Membership Committee, D. H. McDougall, chairman. Report of Meter Committee, L. V. Webber, chairman. Report of Commercial Committee, Thomas F. Kelly, chairman.

12.30 a.m.—Adjournment.

Afternoon.

2.00 p.m.—"Recent Developments in Lamps and Reflectors," J. G. Henninger, illuminating engineer, National Electric Lamp Association. "The Influence of Ice on Water Power Development," Professor H. T. Barnes, D. Sc., F.R.S., McGill University, Montreal. "Distributing Systems for Outlying Districts and Smaller Plants," S. Bingham Hood, Toronto Electric Light Company.

Evening.

7.45 p.m.—Special electric cars will leave Chateau Laurier for Victoria Hotel, Aylmer, where an informal dance and garden party, tendered by the city of Ottawa, will be held. Supper will be served at 11 p.m. and cars will be waiting for return trip at 12 p.m.

Thursday, June 20th.

10.00 a.m.—"Watthour Meters—Past and Present," C. W. Baker, Canadian Westinghouse Company. "New Business," Thomas F. Kelly, Hamilton Electric Light and Power Company. Report of Committee on Rates and Forms of Contract, Parker H. Kemble, chairman.

12.30 a.m.—Adjournment.

Afternoon.

2.00 p.m.—Executive session (Class "A" and "B" members) for election of officers.

2.30 p.m.—Automobile drive from Chateau Laurier to various points of interest in the city, including government system of parks and drives, the Experimental Farm, Governor-General's residence, etc. Light refreshments will be served at some point on the route.

Evening.

8.00 p.m.—Banquet at Chateau Laurier for the registered members of the C.E.A. and guests, and the local committee with ladies accompanying them. Tickets will be furnished by the secretary on application.

Friday, June 21st.

10.00 a.m.—"Power Factor—Its Influence and Effect," D. H. Ross, Wagner Electric Manufacturing Company. "Commercial Electric Heating," McAllister Moore, Belleville. "Underground Construction" (illustrated by moving pictures), G. M. Gest, New York.

12.30 a.m.—Adjournment.

Afternoon.

2.00 p.m.—Report of Committee on Uniform Accounting, D. R. Street, chairman. Report of Public Policy Committee, W. C. Hawkins, chairman. Report of Committee on Standardization of Line Construction, R. G. Black, chairman. Naming of Standing Committee. Next place of meeting. Unfinished business.

3.00 p.m.—Special electric cars will leave Chateau Laurier for baseball grounds, where a game will be played between two C.E.A. teams, one representing the manufacturers, and the other the operating companies.

Evening.

8.00 p.m.—Smoking concert in the Chateau Laurier.

Mr. A. A. Dion, Ottawa, is the president and Mr. T. S. Young, 220 King Street West, Toronto, is the secretary-treasurer.

PERSONALS.

MR. E. O. FUCE, engineer of the municipality of Galt, Ont., has handed his resignation to the town council. He intends to join Mr. Walter Scott in Calgary, Alta.

MR. CUTHBERT C. WORSFOLD has been appointed resident engineer of the Department of Public Works for the province of British Columbia. Mr. Worsfold has been engaged for the past fourteen years as chief assistant to the late Mr. Keefer. He was born at Dover, England, and came to Victoria many years ago, after graduating.

MR. W. ALMON HARE B.A.Sc., president of the Hare Engineering Company, Limited, Toronto, has left for England and the Continent on a business trip. He will be absent about six or seven weeks.

MR. LEWIS C. RANDOLPH has been recently appointed editor of The Canadian Industrial Review, a bright little monthly published by the Canadian Fairbanks-Morse Company, Limited, at 444 St. James St., Montreal. The first number edited by Mr. Randolph is the May issue just received, in which a number of very desirable changes have been made from the former style of the paper. The Canadian Industrial Review is one of the most valuable house organs printed in Canada, and is well worthy of regular perusal by every engineer and contractor.

MR. COLIN H. ADAMS, of Messrs. Adams-Hydraulics, Limited, Sewage Disposal Specialists and Engineers, York, London, etc., in consequence of the large contracts now on hand has sailed for Canada, and will be pleased to call upon civil and municipal engineers who have sewage schemes in hand. Communications addressed to him, c/o Messrs. F. Hankin & Company, 201, Coristine Building, Montreal, will be attended to.

COMING MEETINGS.

CANADIAN ELECTRICAL ASSOCIATION.—June 19th-21st. Annual meeting at Ottawa, Ont. Sec'y, T. S. Young, 220 King St. West, Toronto, Ont.

SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION.—June 26th-28th. Annual meeting at Boston, Mass. Sec'y, H. H. Norris, Cornell University, Ithaca, N.Y.

ONTARIO MUNICIPAL ASSOCIATION.—Annual convention will be held in the City Hall, Toronto, on June 18th and 19th, 1912. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ont.

THE UNION OF CANADIAN MUNICIPALITIES.—August 27, 28 and 29. Meeting at City Hall, Windsor, Ont. Hon. Secretary-Treasurer, W. D. Lighthall, K.C.

CANADIAN FORESTRY ASSOCIATION.—Convention will be held in Victoria, B.C., Sept. 4th-6th. Secy., James Lawler, Canadian Building, Ottawa.

CANADIAN PUBLIC HEALTH ASSOCIATION.—Second Annual Meeting to be held in Toronto, Sept. 16, 17 and 18.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE: Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, S. J. Chapleau, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving; Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, C. E. Cartwright; Secretary, W. Alan, Kennedy; Headquarters: McGill University College, Vancouver.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1290.

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydonejack; Meets every first and third Friday of each month, October to April, in University of Manitoba, Winnipeg.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION.—President, Chas. Hopewell, Mayor, Ottawa; Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm. Mason, Bon Accord, Alta.; Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, W. Sanford Evans, Mayor of Winnipeg; Hon. Secretary-Treasurer, W. D. Lighthall, K.C., Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, Mayor Mitchell, Calgary.; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALTIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang; Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION—President, John Hendry, Vancouver. Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewit, General Manager Consumers' Gas Company, Toronto; J. Keillor, Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President, J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary. H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Jas. Anderson, Gen. Mgr., Sandwich, Windsor and Amherst Railway; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, Killaly Gamble, 703 Temple Building, Toronto.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, J. E. Ganier, No. 5. Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, F. S. Baker, F.R.I.B.A., Toronto, Ont.; Hon. Secretary, Alcide Chausse, No. 5. Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman; Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, J. P. McRae; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Wm. Pierce, Calgary; Secretary-Treasurer, John T. Hall, Brandon, Man.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, 115 Phœnix Block, Winnipeg, Man. Second Monday, except June, July and August, at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc.
Printed forms for the purpose will be furnished upon application.

PLANS AND SPECIFICATIONS ON FILE.

The following Plans (P.) and Specifications (S.) are on file for reference only unless otherwise noted at the office of The Canadian Engineer, 62 Church Street, Toronto:—

Bids close	Noted in issue of
6-17—Electric Generating Station Equipment, Bassano, Alta. ....(S.)	5-30

(Bassano specifications also on file at the office of The Canadian Engineer, Montreal, and the Engineers, Messrs. Bowring & Logan, 322 Donald St., Winnipeg).

TENDERS PENDING.

In Addition to Those in this Issue.

Further information may be had from the issues of The Canadian Engineer referred to.

Place of Work.	Tenders Close.	Issue of.	Page.
Bassano, Alta., electric generating machinery	June 17.	May 30.	74
Berlin, Ont., waterworks improvements		May 23.	72

Regina, Sask., supply of steel, cement, and castings for reservoir	June 14.	June 6.	78
Saskatoon, Sask., garbage incinerator	June 25.	May 2.	74
St. Thomas, Ont., sewers; sewer pipe	June 19.	June 6.	80
Toronto, Ont., steam heating, pumping station	June 18.	June 6.	68
Tisdale, Sask., storm water sewers	June 15.	May 30.	62
Vancouver, B.C., bridge construction	July 8.	May 30.	74
Yarmouth, N.S., dredging	June 13.	June 6.	68

TENDERS.

Arden, Man.—Tenders for the erection of a steel truss bridge, 70 ft. clear span, over the Grassy River, will be received up to noon of July 3rd. Plans and particulars at the Department of Public Works, Winnipeg, and at the office of M. E. Boughton, secretary-treasurer, Lansdowne, Arden, Man. (See advt. in The Canadian Engineer).

Fort William, Ont.—Tenders for the construction of sewers of 4,200 feet, in the Town of Fort Frances, Ont., will be received until June 17th, 1912. Specifications may be seen at the office of J. W. Walker, Clerk.

Fort Wiliam, Ont.—Tenders for the construction of a concrete sewer on Wellington Street will be received until July 5th, 1912. Plans, etc., can be obtained at the office of John Wilson, City Engineer.

Kerrisdale, B.C.—Separate tenders will be received until June 24th, 1912, for the supply of valves, special castings and hydrants required for water supply of the Municipality of Point Grey, B.C. Particulars may be obtained at the office of the engineers Cleveland and Cameron, 506 Winch Bldg., Vancouver. H. Floyd, Clerk Municipal Council, Kerrisdale.

Merritt, B.C.—Tenders addressed to the City Clerk, Merritt, B.C., will be received up to noon of June 15th, 1912, for pipe, specials, valves and hydrants. Plans and specifications may be seen at the office of Dutcher, Maxwell and Co., 319 Pender Street, Vancouver, B.C.

Merritt, B.C.—Tenders addressed to the City Clerk, Merritt, B.C., will be received up to noon of June 15th, 1912, for steam engine generator sets, pumps, transformers, transmission poles and arms. Plans and specifications may be seen at the office of Dutcher, Maxwell and Co., 319 Pender Street, Vancouver, B.C.

New Westminster, B.C.—The corporation invites tenders for paving a number of streets until June 17th, 1912. Tenders will be received for the following types of pavement: Asphaltic, concrete, bitulithic, hassam, vitrified bricks, wood blocks (creosoted). Plans and specifications can be obtained from J. W. B. Blackman, City Engineer. W. A. Duncan, City Clerk, City Hall, New Westminster.

Niagara Falls, Ont.—The Spirella Company of Canada, is about to make a large addition to their factory premises at Niagara Falls, Ont. W. Redpath of Builders' Exchange, Buffalo, N.Y., Architect and Engineer, wants tenders from leading reinforced concrete contractors at once. Particulars can be obtained from W. Redpath.

Oshawa, Ont.—The time for receiving tenders for the construction of 25,000 sq. ft. of concrete sidewalks, has been extended to June 19th, 1912. Frank Chappell, C.E., Town Engineer. (See advt. in The Canadian Engineer).

Ottawa, Ont.—Tenders for an addition and alterations to Public Buildings, Barrie, Ont., will be received at the Department of Public Works, Ottawa, until June 27th, 1912. Plans, etc., can be seen at the office of Mr. Thomas Hastings, Clerk of Works, Postal Station F, Yonge Street, Toronto, at the Post Office, Barrie, Ont., and at the Department of Public Works, Ottawa.

Ottawa, Ont.—The Department of Militia and Defence, Ottawa, are calling for tenders for the construction of new stables at Tete de Point Barracks, Kingston, Ont., up to noon of June 23rd, 1912. Specifications may be seen and full particulars obtained at the offices of the officer commanding, 3rd Divisional Area, Kingston, Ont., and the Director of Engineer Services, Headquarters, Ottawa.

Ottawa, Ont.—Tenders for interior fittings, Post Office, Customs and Inland Revenue, Seaforth, Ont., will be received until June 19th, 1912. Plans and specifications may be seen on application to Mr. R. Wright, Clerk of Works, Seaforth, Ont.; Mr. T. A. Hastings, Clerk of Works, Postal Station F., Toronto, and at the office of R. C. Desrochers, Secretary, Department of Public Works, Ottawa.

Ottawa, Ont.—Tenders for the erection of an operating house (Type No. 3) in connection with a wireless telegraph station at Point Edward near Sarnia, Ont., will be received until noon on July 1st, 1912. Plans, etc., at the office of Superintendent Radio-Telegraph Branch, Department of Naval Service, Ottawa, or at the office of the Post-Master, Sarnia, Ont. G. J. Desbarats, Deputy-Minister, Department of Naval Service, Ottawa.

Ottawa, Ont.—The Department of Public Works, Ottawa, is open to receive tenders for the supply of coal for the Public Buildings, Ottawa, until June 17th, 1912. Combined specification and tender can be obtained and form of contract seen at the office of the Secretary, R. C. Desrochers, Department of Public Works, Ottawa.

Ottawa, Ont.—Tenders for the erection of two 185 feet housing masts in connection with a wireless telegraph station at Point Edward, near Sarnia, Ont., will be received at the office of G. J. Desbarats, Deputy-Minister of the Naval Service, Ottawa, until July 1st, 1912. Full particulars may be obtained at the office of the Superintendent Radio-Telegraph Branch, Department of the Naval Service, Ottawa, or at the office of the Post Master, Sarnia, Ont.

Ottawa, Ont.—Tenders for interior fittings Post Office, Customs and Inland Revenue at Humboldt, Sask., will be received until June 24th, 1912. Plans and specifications to be seen on application to Mr. W. Driver, Clerk of Works, Humboldt, Sask.; Mr. W. T. Mollard, Clerk of Works, Regina, Sask., and at the office of R. C. Desrochers, Secretary, Department of Public Works, Ottawa.

Port Arthur, Ont.—The Board of Education is calling for tenders for a 12-room school. Estimated cost $70,000. Messrs. Hood & Scotts, architects.

St. Catharines, Ont.—Tenders will be received by the Board of Works up to noon of July 3rd, 1912, for the construction of Berryman Avenue Trunk Sewer. R. D. Brown, Esq., City Engineer, St. Catharines. (See advt. in The Canadian Engineer).

St. John, N.B.—The city of St. John invites tenders for the following works, viz.: Excavation, backfill and cartage for water mains, in a number of streets and also the laying of bituminous concrete sidewalks in several streets. Plans and specifications are to be seen in the office of the City Engineer, Room No. 5, City Hall. R. E. Wigmore, Commissioner Water and Sewerage, M. E. Agar, Commissioner Public Works, St. John, N.B.

Toronto, Ont.—Tenders for the construction of Section No. 12, High Level Interceptor, will be received up to noon of July 2nd, 1912. Plans, etc., can be obtained at the office of the Acting City Engineer, Toronto. G. R. Geary, (Mayor), Chairman, Board of Control. (See advt. in the Canadian Engineer).

Toronto, Ont.—Tenders for the erection of a dormitory building, excepting heating, plumbing and lighting, on the grounds of the Institution for Deaf and Dumb, Belleville, will be received up to noon of June 17th, 1912. Plans and specifications can be seen at the office of H. F. McNaughten, Secretary, Department of Public Works, Ontario, Toronto.

Winnipeg, Man.—Tenders for the installation of a heating and ventilating plant in the Laura Secord School will be received at the office of the Winnipeg School Board, until June 18th, 1912. Plans, etc., at the office of J. B. Mitchell, Commissioner of School Buildings, School Board Offices. R. H. Smith, Secretary-Treasurer, W.P.S.B.

Winnipeg, Man.—Tenders will be received up to noon of June 17th, 1912, for the manufacture and delivery f.o.b. Winnipeg, of the following supplies, viz: 100 fire alarm box holders; 75 police box holders; 80 fire alarm signal lamp supports. Plans, etc., may be obtained at the office of the City Electrician, City Hall. M. Peterson, Secretary, Board of Control Office, Winnipeg.

Winnipeg, Man.—Tenders for the erection of a stone and brick school on the Lord Selkirk Site, will be received until June 18th, 1912. For plans, etc., apply to J. B. Mitchell, Commissioner of School Building, School Board Offices, Winnipeg.

Winnipeg, Man.—Tenders for the manufacture, delivery and installation complete of 31,000 k.w. transformers will be received up to noon of June 14th, 1912. Full particulars may be obtained at the office of the City Light and Power Department, 54 King Street. M. Peterson, Secretary, Board of Control Office, Winnipeg.

Winnipeg, Man.—Tenders are being called for the construction of another sixty-five miles of the Hudson's Bay Railway, and tenders covering the remainder of the road will be called for very shortly.

CONTRACTS AWARDED.

Berlin, Ont.—The Waterworks Commission has awarded the contract for constructing a million-gallon reservoir in connection with the new $100,000 extension plant to Mr. John Paterson, of St. Mary's, at a cost of $15,450. A new $500,000 standpipe will also be erected.

Gosford, Que.—Messrs. P. Lyall and Sons, Transportation Building, Montreal, have received the contract for the demolition of old buildings and the erection of the Montreal City Hall Annex, in Gosford. Contract price, $649,000.

Fredericton, N.B.—Another contract for the construction of the St. John Valley Railway, the line from Woodstock to Meductic, has been awarded to Messrs. John S. Scott & Company, of Fredericton.

London, Ont.—The contracts for the construction of the factory of the Dominion Abattoir, Limited, at Pottersburg, have been awarded by Moore and Munroe, architects. Joshua Garratt will do the brick work, Tambling and Jones the carpenter work, and the London Foundry Company the iron work.

Montreal, Que.—Tenders for the excavation and foundation work in connection with the new High School building, were opened from the following firms:—John Quinlan and Company, $235,000; Reid, McGregor & Reid, $254,000; E. G. M. Cape, $281,000; P. Lyall and Sons Construction Company, $295,000; Geo. A. Fuller Company, $284,000. The tender from John Quinlan and Company, for $235,000, was accepted. Architect, Mr. Wm. Maxwell.

Moose Jaw, Sask.—The contract for the erection of St. Andrew's Church has been awarded to Mr. A. B. Anderson, of Winnipeg, his tender for $120,695 being the lowest received.

Outlook, Sask.—This town has just placed a contract with the British Canadian Engineering and Supply Company, Limited, of Winnipeg, for a 72 brake horse-power Ruston Proctor producer gas engine and plant, together with a Westinghouse generator.

Saskatoon, Sask.—The city council have closed a contract with Messrs. Stone and Webster, a Boston engineering and contracting company, for the construction of the street railway and the financing of the undertaking for a year.

Toronto, Ont.—Messrs. Siemens Brothers' Dynamo Works have received a repeat order for the city of Regina for a 400 K.W., 550/600 Volt, 450 R.P.M., direct current, compound wound generator with commutation poles. The generator will be direct coupled to a Belliss & Morcom vertical high-speed engine.

Toronto, Ont.—An order for a 150 K.W., 475 R.P.M. compound wound, direct current, 3-wire generator for the Winnipeg General Hospital, has been placed with Messrs. Siemens Brothers' Dynamo Works. The generator will be direct coupled to a high-speed vertical engine. A switch panel for controlling the generator is also being supplied by Siemens.

Toronto, Ont.—A repeat order from the city of Port Arthur, Ont., for a 500 K.W., 450 R.P.M. motor generator set, has been received by the Siemens Brothers' Dynamo Works. The motor is of the synchronous type, having an output of 750 b.h.p., on a 3-phase, 60-cycle, 2,200 volt system. The generator has an output of 500 K.W., 550/600 volts, is compound wound, and has commutation poles with Siemens two-piece commutator. A two-panel switchboard is also being supplied to control the above set.

Toronto, Ont.—Messrs. Siemens Bros.' Dynamo Works have received the order for the following apparatus for the city of Edmonton.

Dolarway Pavement

"It is permanent because it is concrete."

The Last Word In Street Pavements

The Dolarway Pavement is popular with City Officials, Highway Engineers and Property Owners because:

It is low in first cost.
Its maintenance cost is lower than that for any other permanent form of Pavement.
No paving plant is required to either construct or maintain it.
It is noiseless, dustless and resilient.
Its traction qualities for both the Horse and the Automobile are of the best.

For full particulars address

DOLARWAY PAVING COMPANY

95 Liberty Street, New York City 510 Title & Trust Bldg., Chicago, Ill.

Applying Dolarway Bitumen on Concrete Base, Central Park, N.Y. City.

1—2,000 K.W., 3,600 R.P.M., 3-phase, 60 cycle, turbo generator for direct coupling to a Willans & Robinson turbine.
1—750 K.W., 280 R.P.M., direct current, 500/575 volt compound wound generator with commutation poles for direct coupling to a Belliss & Morcom high speed vertical engine.
1—425 H.P., 3-phase, 60 cycle, 450 R.P.M., slip-ring motor with short circuiting and brush lifting device.

Medicine Hat, Alta.—The contract for the Ogilvie Mills has been let to Messrs. James Stewart & Company, of Chicago. The iron is to be supplied by the Alberta Rolling Mills.

Vancouver, B.C.—A report states that contracts for construction for a $400,000 steam auxiliary plant on Vancouver Island have been recently awarded to Messrs. C. C. Moore & Co., of Seattle and San Francisco. W. H. Haylitt, purchasing agent.

RAILWAYS—STEAM AND ELECTRIC.

Guelph, Ont.—The management of the Guelph Radial Railway decided to purchase a snow sweeper at a cost of $4,000.

LIGHT, HEAT AND POWER.

Brockville Ont.—A member of the Hydro-Electric Power Commission, field staff, is at present engaged in the vicinity of Brockville and Kingston, going over the different routes, to select a route and station site, for the proposed 66,000 volt line from a supply point near Morrisburg. He is also looking up a route and station site for the 13,200 volt supply lines between Prescott, Cardinal, Morrisburg and Lyn.

Moose Jaw, Sask.—The municipal council has resolved to place an order with the Canadian General Electric Company for a 1,000 k.w. three phase generator to be shipped at an early date.

Ridgetown, Ont.—The ratepayers of this municipality voted in favor of the purchase of the electric light plant at a price of $10,500.

Saskatoon, Sask.—The ratepayers voted their approval of spending $175,000 on electric light and power machinery, and $80,000 for extension to the distributing system.

Saskatoon, Sask.—A report prepared by the civic electrician shows that during May 241,539 k.w. of electricity were generated by the city's power plant. This is an increase of 68 per cent. over the amount generated in the same month last year.

53,357,442 gallons of water were pumped at the city's pumping station, or an increase of 76 per cent. on the corresponding month of last year.

These figures represent an increase in the income for May, 1912, of 40 per cent.

Welland, Ont.—A report has been presented to the council and that body will consider a municipal lighting plant operated by the Hydro-Electric Commission.

GARBAGE, SEWAGE AND WATER.

Edmonton, Alta.—The water pumping facilities of this city are to be increased by the addition of a ten-million gallon and a six-million gallon unit.

Ingersoll, Ont.—The cost of the proposed sewage system will be about $60,000. Mr. W. Chipman, of Toronto, is engineering the project.

Saskatoon, Sask.—The ratepayers voted in favor of spending $50,000 on the construction of a storm sewer.

Toronto, Ont.—Acting City Engineer Powell has stated in a report that the cost of the proposed extension to the filtration plant will be $877,000. The work includes a second plant of thirteen filters an additional steel intake and a chlorination plant.

Kerrisdale, B.C.—There is a probability of the council calling for tenders for a water supply from Point Grey reservoir. Messrs. Cleveland and Cameron are the engineers of this proposed work.

BUILDINGS AND INDUSTRIAL WORKS.

Berlin, Ont.—The members of the Berlin Tuberculosis Association will ask the municipal council for a grant of $15,000 for the purpose of purchasing property near Freeport on which will be erected a suitable sanitarium.

Berlin, Ont.—The Board of Health will reccommend that the municipal council pass a by-law calling for the erection of a civic abattoir.

Edmonton, Alta.—A building permit has been issued, for the new building of the Edmonton Brewing and Malting Company, to be erected on 21st Street. This building will be of concrete, steel, and brick construction, and practically fireproof. The plant when completed will comprise the most modern equipment, and will entail an expenditure of approximately $450,000.

Edmonton, Alta.—The City Commissioners have let contracts for a six story office building to cost $225,000, for the accommodation of the officials of the various civic departments.

Montreal, P.Q.—Plans have been prepared for the erection of a large commercial building for the A. Sommer Company. It will be ten stories in height.

Moose Jaw, Sask. — The managers of St. Andrew's Church have been instructed by the congregation to proceed with the erection of a new church building at a cost of $120,695.

New Glasgow, N.S.—A subsidiary company of the Nova Scotia Steel and Coal Company, called the Eastern Car Company, was formed here recently with capitalization of $2,500,000. It is intended to build steel freight cars near the present mills, the works having a capacity of 25 per day. A master car builder, formerly connected with the American Car and Foundry Company, of Detroit, has been engaged and is now preparing plans and estimates, and it is expected to break ground within the next ten days.

Port Arthur, Ont.—The Drydock & Shipbuilding Company will construct the following buildings this season:—power house 50 ft. x 105 ft.; warehouse 60 ft. x 120 ft.; joiner shop, 60 ft. x 160 ft. A syndicate will erect an eight-story office building, estimated cost $500,000. Architect is David R. Brown, of Montreal. Jas. Whalen is interested.

Regina, Sask.—The municipal council are considering the matter of erecting a collegiate institute building at a cost of $100,000.

Saskatoon, Sask.—The ratepayers will vote on a proposition which calls for the granting of a free site and other concessions to the management of the Quaker Oats Company who propose to erect a milling plant in this city.

Saskatoon, Sask.—Mr. F. R. MacMillan is considering the details of construction previous to calling for tenders for the erection of a new department store building.

Stratford, Ont. — The congregation of the Lutheran Church, Berlin, Ont., propose the erection of a church building on property recently acquired at the corner of Church and Benton Street.

Palmerston, Ont.—Messrs. Taylor, Scott and Company, of Toronto, who have recently purchased the woodworking establishment of Major Wooldridge, intend erecting a substantial addition on the present premises.

Thunder Bay District.—The Government will locate a prison farm in Neebing Township. The buildings, etc., will cost about $50,000. Dr. Bruce Smith, of Toronto, is superintendent of government institutions.

Toronto, Ont.—The Toronto Harbor Commissioners contemplate spending about $5,000,000 on the improvement of the Ashbridge's Bay district, and in a few days it is probable the plans for the big undertaking will be passed by the Commissioners.

Vancouver, B.C.—Preliminary work, preparatory to starting construction on the new Canadian Pacific Railway depot, has commenced. Messrs. Westinghouse, Church & Kerr, of New York, are the engineers for this project.

BRIDGES, ROADS AND PAVEMENTS.

Montreal, P. Q.—The municipal controllers are considering a report on a proposed bridge between Montreal and St. Helen's Island. The cost of the structure is estimated at $10,000,000.

Oshawa, Ont.—The time for receiving tenders for cement paving has been extended to June 19th. (See advt. in The Canadian Engineer.)

Province of British Columbia.—A delegation from this province will meet in Ontario to press the matter of the construction of a bridge to Vancouver Island. Should this receive favorable attention from the Government the cost would be about $20,000,000, and it would be one of the largest bridge structures in the world.

FIRES.

Cobalt, Ont.—A large section of the business block of this town was damaged by fire. The loss is estimated at $40,000.

Montreal, P.Q.—The plant of the Peck Rolling Mills was damaged by fire to the extent of $25,000.

Penetanguishene, Ont.—Considerable damage was caused by fire to the plant and mills of the C. Beck Manufacturing Company. Several new pieces of machinery are destroyed.

Portage la Prairie, Man. — The round-house, telegraph office, store-room, oil-house and paint shop of the Grand Trunk Pacific Railway were gutted by fire.

Prince Albert, Sask.—The buildings of the Prince Albert Foundry Company were damaged to the extent of $21,000 by fire.

CURRENT NEWS.

Berlin, Ont.—Mr. J. Walters, of Chicago, Ill., U.S.A., has opened negotiations with the municipal council with a view of establishing a wood pulp manufactory.

Kerrisdale, B.C.—The extent and cost of the relative civic works which have been or are being carried out this year are as follows:—Clearing and grubbing, 10.1 miles, cost $17,000; clearing, grubbing and contour grading, 6.5 miles, cost $69,000; box drains, 4,500 feet, cost $900; macadamizing, 12 miles, cost $100,000; road planking, 1 mile, cost $3,700; wooden sidewalks, 5 miles, cost $4,700; cement sidewalks, 0.3 mile, cost $1,100; bithulithic paving, including curbs, 2.6 miles, cost $66,000; sewers, 13 miles and sewer connections, 3 miles, cost $358,000—making a total of $642,400.

Medicine Hat, Alta.—The municipal authorities are about to open a milk testing laboratory.

New Glasgow, N.S.—The first forging by steam hydraulic presses ever attempted in Canada was successfully carried out recently at New Glasgow before the directors of the Nova Scotia Steel and Coal Company.

New Westminster, B.C.—The ratepayers will be asked to vote on by-laws involving an expenditure of over $1,000,000. This work involves improvements to the harbor, water works extension, erection of a new reservoir, construction of a new hospital, construction of a new police station, construction of a storehouse and a municipal gas plant.

St. John, N.B.—Messrs. Norton Griffiths Company, contractors for the harbor improvements of St. John, have filed plans at Ottawa for the construction of a large drydock. The estimated cost of this work is placed at $4,000,000.

Welland, Ont.—A report from this municipality regarding building is as follows:—Building permits for month of May, 1912, are $30,968; building permits for month of May, 1911, no record; total for year to date this year is $104,873; total for year to date last year, no record.

Western Canada.—Owing to the shortage in cement the Government has reduced the duty on this article by 50 per cent.

ENGINEERING NOTES.

Edmonton, Alta.—The operation of the municipal street railway for the half-year still shows a small deficit.

Edmonton, Alta.—The operation of the municipal electric light department for the past six months shows a profit of $57,000.

Edmonton, Alta.—The operation of the municipal telephone system for the past six months shows a profit of about $8,000.

Montreal, P.Q.—A brick chimney, the property of Messrs. R. McFarlane & Sons, was successfully straightened by a delicate operation. The structure has a height of 129 feet, and recently sagged until the top was four feet six inches forward of the bottom. Four layers of brick were taken from the left side of the chimney and after each layer had been taken out the chimney was propped up and allowed to come down the three inches. This is the first time that such an operation has been successfully carried out in Canada. It has been performed several times in England.

Northern Ontario.—A party with Mr. W. J. Donaldson, at the head has left Cobalt and are on the way to Clark Island, James Bay, for the purpose of working large iron deposits staked out five years ago by Mr. Curran and Dr. Adams.

Toronto, Ont.—A delegation of marine men from Great Britain, France, Germany, Denmark, Russia, Belgium, Spain, Italy, Switzerland, Norway, Roumania, Hungary, Egypt, Mexico, Cuba, Brazil and the United States, visited the harbor of Toronto on June 13th. These are the delegates from the International Congress of Navigation which met recently in Philadelphia, P.A., U.S.A.

RAILWAY SHOPS AT TRANSCONA, MANITOBA.

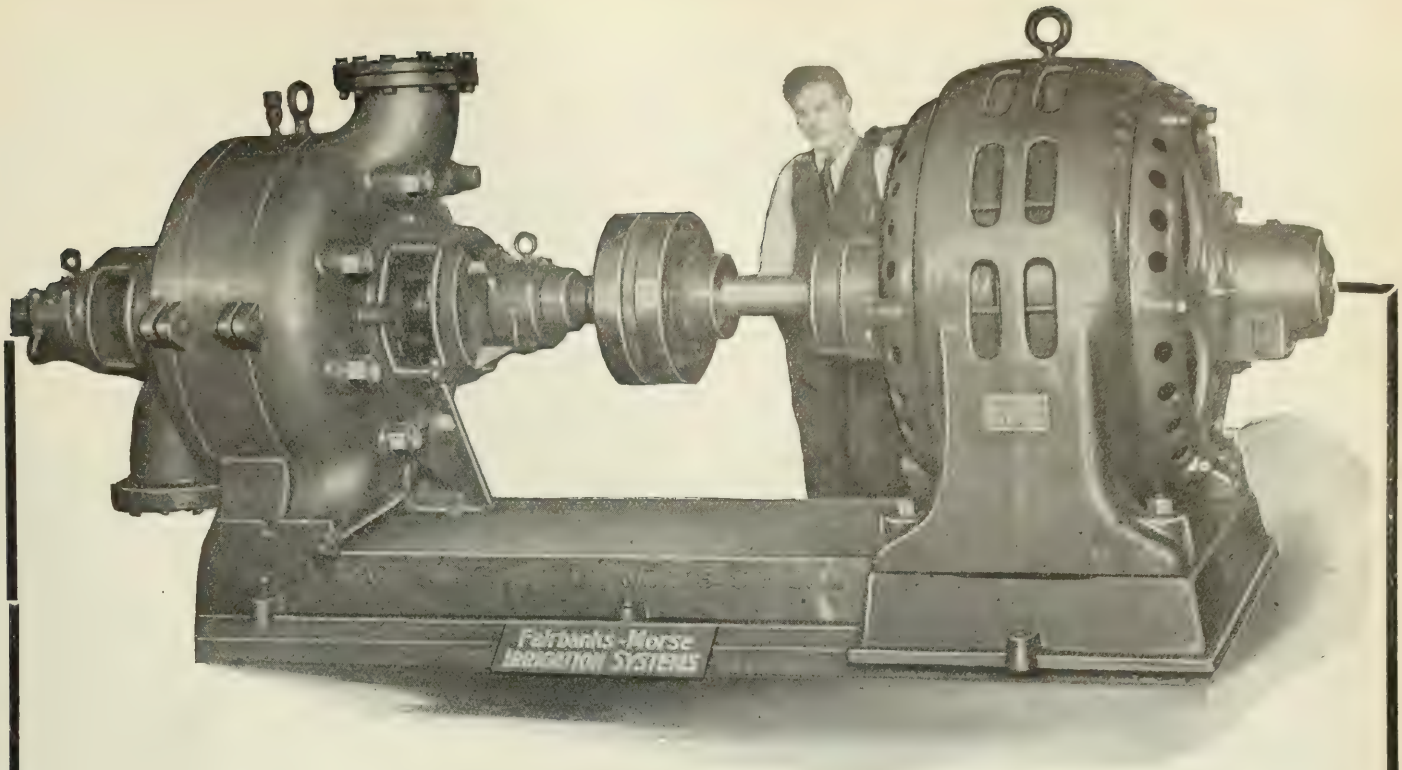
The Grand Trunk Pacific shops at Transcona, Man., which were opened for operation on June 1, are among the largest, and are said to be the most modern and the most completely equipped on the continent.

The locomotive shops are 600 feet long with an additional section at the east end for use as a boiler-making room, which is 200 feet in length. Running the entire length of the building is a large 120-ton travelling crane with a smaller 10-ton crane on a track below it. On the south side of the building are also two ten-ton travelling cranes, while on the ground floor are a number of machines to be used in locomotive construction and repair; hydraulic presses and hammers, etc., steel working machines.

One of the most interesting machines in this shop is an immense eighteen-foot gap riveter, which is capable of handling the largest locomotive boilers and riveting them from end to end without turning over. The heaviest, perhaps, is the hydraulic accumulator in the boiler room which supplies hydraulic pressure to the other machines at a pressure of 1,500 pounds per square inch, and weighs about sixty tons. In these shops, together with the foundry and other buildings, it will be possible to build not only complete locomotives, but freight and passenger cars.

Construction is being rapidly pushed on the car shops and the steel skeletons are rapidly taking form. They will be 600 by 225 feet in area and will build or repair all kinds of wood and steel frame cars. At the west end the framework of two coach shops has already been erected where the first-class sleepers and diners to be used on the new road will be built.

The proprietors of several hastily constructed sheet metal buildings in Edmonton have experienced trouble by legal charges which name them as breakers of the building laws. An effort will be made by several merchants to determine the exact status of persons erecting buildings of this material, and will contend the point as to whether or not galvanized tin or sheet iron which forms the walls of the many movable stores and shoe-shining parlors along First and other streets, can be considered non-combustible.



The Largest Direct Connected Centrifugal Pumping Unit in British Columbia.

The Vancouver Power Company have recently installed at their works at Coquitlam Dam, B.C., the largest direct connected centrifugal pumping unit in British Columbia. This outfit is to operate in parallel with a number of other pumps that are to furnish water under pressure for sluicing into place the material for their new dam.

This pump is a 10-inch, class "F," two-stage centrifugal, with bronze inpellers and renewable bronze diffusion vanes. It has a normal capacity of 1833 imperial gallons per minute when operating at 1160 r.p.m. against a total head of 355 feet or an equivalent pressure of 154 lbs. per square inch. It is mounted on a common sub-base with a 300 h.p. type "B," Fairbanks-Morse squirrel cage, induction motor, 2200 volts, 60-cycle, 3-phase, 1160 r.p.m. at full load being direct connected thereto by means of a flexible leather link coupling

The motor possesses a feature in rotor construction that is unique. The end rings are welded on to the rotor bars by a new process, making a perfect joint, free from the troubles common to the purely mechanical or riveted joint, such as oxidation, working loose, and solder-throwing. This improvement marks a long step forward in the elimination of rotor trouble.

Our Vancouver Branch supplied and assembled this complete pumping unit. We are in a position to quote on the necessary equipment for any pumping requirements on receipt of specifications.

CORRECTION.

In our issue of May 23rd we published an item under the heading of "Contracts Awarded" to the effect that the Niagara Falls Canning Company were about to increase their plant by the expenditure of $100,000 for an addition. We are informed from Niagara Falls that the item referred to the Sanitary Canning Company, and that the work will involve an expenditure of $60,000.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from The Canadian Engineer for small fee.

16564—May 21—Approving revised location of C.N.O. Ry. (Toronto-Ottawa Line) west of Newburgh, Twp. of Camden, Ct. Addington, Ont.

16565—May 21—Authorizing C.N.O. Ry. to cross public road between Lots 20 and 21, Con. 2, Twp. of Thorah, Ontario.

16566—May 21—Authorizing G.T.P. B.L. Co., and C.P.R., to operate over interlocker at crossing of Melville-Regina Branch of G.T.P. B.L. Co., and C.P.R. Bulyea Branch.

16567—May 21—Authorizing C.N.O. Ry. to construct bridge over Otter Creek, at mileage 204 from Toronto, Ontario.

16568—May 22—Directing C.P.R. to install within 90 days electric bell at Main Trail near Hesperus, Alta. 20 per cent. from Railway Grade Crossing Fund. (Lethbridge Subdivision).

16569—May 15—Approving diversion and crossings in R. M. Purdue, No. 346, Saskatchewan, across C.P.R.

16570—May 22—General Order Fire Prevention on Railways.

16571—May 21—Authorizing St. Railway, Fort William, Ont., to operate cars over crossing of C.P.R. at Pacific Avenue.

16572—May 21—Approving plan "A" for subway under C.P.R. at 9th Avenue, East Calgary, Alta. (C. & E. Branch C.P.R.).

16573—May 21—Authorizing C.P.R. to cross with its Swift Current Northwesterly Branch (formerly Swift Current to Brooks Branch), 25 highways and approving location mileage 78.00 to 111.14.

16574—May 21—Authorizing C.P.R. to construct extension to spur of Dominion Gypsum Co., Ltd., Winnipeg, Man.

16575—May 22—General Order Re Forged Steel Wheels on Tender Trucks.

16576—May 22—Authorizing C.P.R. to construct cement foot subway under its tracks at George St., Smith's Falls, Ontario.

16577—March 8—Directing C.N.O. Ry. to maintain and erect a flag station at the eastern extremity of Deaf & Dumb Institute Grounds, near Belleville, Ontario.

16578—May 23—Approving agreement between Bell Telephone Co. and Algoma Steel Co., Ltd., Sault Ste. Marie, Ontario.

16579—May 22—Authorizing G.T.R. to use and operate jointly with C.P.R. spur to Toronto Furniture Co., Toronto, Ont.

16580—May 23—Authorizing C.P.R. to construct its second main line track across 5 highways on its Kenora, S.D., Man.

16581—May 23—Authorizing C.P.R. to construct spur to premises of Western Foundry & Machine Co., Ltd., Saskatoon, Sask.

16582—May 22—Authorizing Dominion Atlantic Ry. to construct its North Mountain Ry. Branch across highways between Centreville and Weston.

16583—May 23—Authorizing C.N.O. Ry. to construct bridge over Riviere des Milles Isles at mileage 37.9, from Hawkesbury, Ont.

16584—May 23—Authorizing C.N.O. Ry. to cross three highways in Township of Bristol, County of Pontiac, Que.

16585—May 9—Authorizing C.N.O. Ry. to connect its line with siding of Canada Cooperage Co. at Smith's Falls, temporarily.

16586—May 23—Approving revised location of C.N.O. Ry. in Twps. of Ross & Westmeath, Ct. Renfrew, mileage 69.15 to 71.08, from Ottawa.

16587—May 22—Authorizing C.N.O. Ry. to construct spur to premises of Shevlin Clarke Lumber Co., Ltd., Fort Frances, Ontario.

16588—May 23—Authorizing parish of St. Cuthbert, Ct. Berthier, Que., to construct highway across C.P.R., 2 miles east of St. Cuthbert.

16589—May 20—Approving location of G.T.P. Ry. through city of Fort William, Ont., in accordance with agreement between city and C.P.R., rescinding Order 8493, of Oct. 6th, 1909.

16590—May 27—Authorizing G.T.R. and C.P.R. to operate trains over interlocker at Nipissing Jct., without coming to a stop.

16591—May 27—Approving revised location of Toronto Eastern Ry. Co. through Twps. of Whitby and Whitby East, Ct. Ontario, Ontario.

16592—May 23—Authorizing G.T.P. to construct a (farm) crossing over C.P.R. near dock in city of Vancouver, B.C.

16593—May 27—Approving revised location of C.N.O. Ry. through Townships of Gibbons and Crerar, mileage 267.2 to 271.4, from Ottawa, in Nipissing District.

16594—May 27—Approving location of C.N.Q. Ry. through Counties of Two Mountains and Terrebonne, mileage 16.71 to 33.04, in Quebec.

16595-96—May 27—16597—May 23—Approving location of C.N.R. through Twps. 39-42, Rge. 1, west 3rd M., to 27 west 2 M., mileage 0.00 to 26.56, and location of C.N.R. (Alsask Southeasterly Line) through Twps. 25-26, Rges. 15-20, west 3rd M., mileage 42.59 to 85.24; authorizing C.N.R. (Strathcona-Camrose Branch) to cross C.P.R. Calgary-Edmonton Branch in N.W. ¼ of Sec. 16, Twp. 52, Rge. 24, west 4 M. Alberta interlocker to be installed.

16598—May 23—Authorizing Campbellford, Lake Ont. & Western Ry. to join its tracks with Ontario & Quebec Ry. (C.P.R.) at Glen Tay Ontario. (All C.P.R. roads).

16599—May 27—Approving revised location of Campbellford, Lake Ont. & Western Ry. (C.P.R.) at Glen Tay to mileage 2.08, miles.

16600—May 23—Authorizing C.P.R. to construct three additional tracks across Wolever Avenue and public lane in city of Winnipeg, Manitoba.

16601—May 27—Approving revised location of C.P.R. from mileage 0, at Bassano, for a distance of 35.38 miles, in 3-25-22 west 4 M.

16602—May 23—Authorizing C.P.R. to take certain lands of Toronto Belt Line Co., in connection with diversions of St. Clair Avenue and Scarlett Road, Toronto, Ont.

16603—May 27—Refusing application of Bell Telephone Company re crossing of Brock Ave. tracks of C.P.R. and G.T.R., Toronto.

16604—May 27—Authorizing C.N.O. Ry. to cross public road on Lot 21, R. 2, in Twp. of Clarendon, Ct. Pontiac, Que.

16605—May 28—Authorizing Alberta Central Ry. (C.P.R.) to divert trail at Rocky Mountain House, Alberta, by means of overhead bridge.

16606—May 28—Authorizing Esquimalt & Nanaimo Ry. to construct bridge No. 4.5 near Victoria, B.C.

16607—May 27—Refusing application of Campbellford, Lake Ont. & Western Ry. for crossing of G.T.R. at mile 70.74 from Glen Tay, Ont.

16608-09—May 27—Authorizing C.P.R. to construct spurs for Wm. Bannerman Co. ballast pit at mileage 2, Ignace S.D., Ont., and ballast pit spur for Ernest Hogg, near Agassiz, B.C.

16610—May 28—Authorizing C.N.O. Ry. to temporarily cross Con. Road in Twp. Georgina, Ont., by agreement with Twp.

16611—May 28—Authorizing C.P.R. to join its tracks with G.T.R. take certain lands necessary and to divert lanes, etc., near Clarence Square, Toronto, for freight purposes in connection with enlarging freight terminals.

16612—May 27—Extending until July 1st, 1912, time for completion of branch line authorized by Order 15542, November 22, 1911, C.P.R. (Credit Valley Ry.).

16613—May 28—Further extending until December 1st, 1912, C.R.C., No. 5, Telegraph Tolls of C.P.R.

16614-15-16-17—May 28—Authorizing C.P.R. to construct two branch lines for Henry S. Green, Parish of Kildonan, near Winnipeg, Man.; for Canada Sand-Lime Pressed Brick Co., Symes Road, Toronto, Ont.; for British Columbia Brass, Ltd., New Westminster, B.C.; for Argenteuil Granite Co., Ltd., Township of Chatham, Ct. Argenteuil, Que.

16618—May 27—Authorizing G.T.P. and Midland Ry. Co. of Canada to operate their trains over interlocker at Parish Lot 55, St. Boniface, Man., without stopping.

16619-20-21-22-23-24—May 28—Extending until December 1st, 1912, tariffs of tolls of G.N.W., G.T.P., C.N.R., White Pass & Yukon, North American, and Bell Telephone, Telegraph and Telephone Companies authorized by former Orders or Acts, 7-8 Edward VII., Chapter 61.

16625—May 29—Extending until July 1st, 1912, time for completion of fencing by G.N.R. directed by Order 16131.

16626—May 23—Directing C.N.R. to install an improved type of electric bell at Bay Bridge Road, Belleville, Ont.

16627—May 28—Authorizing V. V. & E. Ry. to construct dock and warehouse at Burrard Inlet, B.C. Rescinding Order 15093 of Oct. 16, 1911.

16628—May 29—Approving revised location of C.N.O. Ry. through Twp. of Clarendon, Ct. Pontiac, Que., mileage 55 to 58 from Ottawa.

16629—May 29—Authorizing C.N.R. to divert public road on its Swift Current Extension, Saskatchewan.

16630-31-32—May 30—Approving plans for bridge No. 61.51 on Woodstock, S.D., C.P.R., and authorizing C.P.R. to reconstruct bridge 58.59 on Cartier S.D., and bridge 57.1 on Cascade Subdivision.

16633—May 29—Authorizing G.T.R. to reconstruct bridge carrying public highway in Twp. of Caradoc, 18 District, Middle Division, County of Middlesex, Ont.

16634-35-36—May 30—Refusing application of city of Hamilton to cross with extension of Lottridge Street, the T.H. & B. Ry., Hamilton Radial Ry., and G.T.R.

16637—May 29—Relieving G.N.R. from erecting and maintaining fences from International Boundary to Bunclody, and from Bunclody to Brandon, Man.

16638—May 29—Authorizing Essex Terminal and M.C.R. to operate trains over crossing at Windsor, Ont., without stopping.

16639—May 29—Extending until July 1st, 1912, time for installing of derails by G.T.R. under Order 16411, April 19, 1912.

16640—May 28—Authorizing city of Lethbridge to construct across C.P.R. at 13th Street crossing for one year watchman or watchmen to be employed by city.

16641—May 29—Extending until 31st August, 1912, time for completion of work required by Order 15770, Jan. 11, 1912, diversion of highway and crossing of C.P.R.

16642—May 29—Authorizing G.T.R. to construct additional track across Bedford Street, Brantford, Ontario.

16643—May 30—Authorizing Quebec Railway, Light, Heat & Power Co. to construct siding into premises of Beaupre Sand Co., Ste. Anne de B., Que.

16644—May 29—Authorizing Michigan Central Railroad Co. to construct siding into premises of Dominion Canners, Ltd., in town of Niagara-on-the-Lake, Ontario.

16645—May 29—Approving location of V.V. & E. Ry. (G.N.R.) station grounds at White Rock, Province of British Columbia.

16646—May 23—Authorizing C.N.O. Ry. to connect its lines and tracks with C.P.R. at Meadowsite, Dist. of Nipissing, Ont., for a period of 5 months for construction purposes only.

16647—May 30—Approving location of C.P.R. Kerrobert Northeasterly Branch from mileage 20 to 36.08, Saskatchewan.

The Canadian Engineer

An Engineering Weekly

TIMISKAMING DAM CONSTRUCTION.

The second annual report of Mr. C. R. Coutlée, the engineer in charge of the construction of storage reservoirs on the Upper Ottawa River, has recently been published by the Department of Public Works. An abstract of the report dealing with the Timiskaming dam construction follows.

For several years prior to the commencement of the Georgian Bay ship canal survey in 1904, by the Department of Public Works, it was felt that something should be done to improve the conditions of low water on the Ottawa River. which made navigation difficult during the fall of low years, and crippled badly some of the power developments on the river. Representations were made to the Federal Government that the only possible remedy was to establish some system of storage reservoirs at the head waters of the Ottawa River, by which some of the surplus waters in the spring could be collected and conserved to be released gradually during the low period and thus augment the low flow.

crease the low water flow in time of deficiency, and that this control would not only be of benefit to navigation, but would be of great advantage to all commercial and industrial interests on the river depending on water for power and transportation.

Moreover the fact that large communities depend on an adequate and permanent river flow for the necessities of life, such as water supply for domestic purposes and fire protection, and the economical production of electrical energy for lighting tramways, industries, etc., gives to this control a national and vital importance. For these public utilities a shortage of water becomes a serious matter, as was exemplified in 1905 by the helpless condition of the powers at the Chaudière Falls on the Ottawa River on account of the long period of extremely low flow.

During the session of 1908-9, parliament voted the sum of $65,000 to commence the construction of storage dams

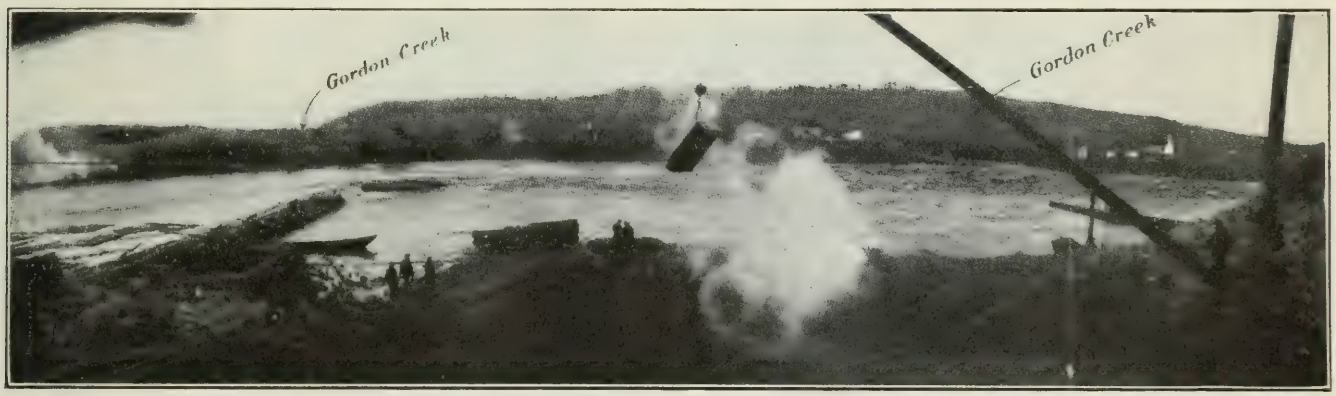

Fig. 1.—Timiskaming Dam, November, 1910. Coffer Dams, Quebec Channel, Stopped by Autumn Floods.

In 1904, Mr. George Brophy, superintending engineer, Ottawa River works, was commissioned by the Department of Public Works to carry on a preliminary investigation of the storage possibilities, the work having been recognized as of Federal importance. The result of his investigations is published in the report of the Georgian Bay ship canal, page 303.

During the extensive surveys made for the proposed Georgian Bay ship canal, and in elaborating a project for a first-class waterway, it was soon seen that no satisfactory scheme could be devised unless it included an efficient partial control by storage of the spring floods of the Ottawa River throughout its watershed, in order to reduce the fluctuations in the different reaches, to eliminate swift and dangerous currents, and to establish practically slack water navigation.

In the report on that waterway, it was shown that conditions in the upper Ottawa River were favorable to a partial control of the surplus waters which could be used to in-

on the Ottawa valley, previously recommended by Mr. G. P. Brophy, superintendent of Ottawa River works. Another sum of $20,000 was voted to continue the preliminary studies already commenced of the Ottawa River watershed.

Having been promoted to the position of Assistant Deputy Minister in the department, Mr. C. R. Coutlée, C.E., was appointed engineer in charge of the whole storage work, under the direction of the chief engineer, it being understood, however, that the work would be continued under my general supervision in an advisory capacity.

The report presented, after a brief review of the preliminary works performed in relation to storage during the survey for the canal, treats of the present waterpower development on the Ottawa River, the different lakes along its course, the characteristics of its watershed, its flow, etc., and gives figures as to the possible amount of water which can be stored in the natural reservoirs which it has been possible, so far, to investigate and study with a fair degree of accuracy.

It shows that storage so far in sight, and for which controlling dams are either under construction or sites fully surveyed and contract plans under way are:—

Basin.	Area. sq. miles.	Maximum Possible Depth. feet.	Storage. sq. miles feet.
Lake Timiskaming	100	20	2,000
Lake Kipawa	100	20	2,000
Lake Quinze and Expanse.....	100	20	2,000
Total			6,000

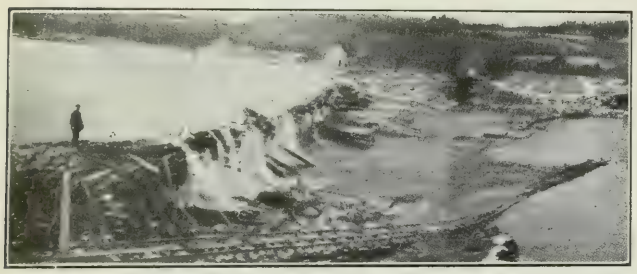

Fig. 2.—Timiskaming Cofferdam, Quebec Channel, 3rd May (Day Before Failure), Lake Surface Elevation 580.50. The Pit was Flooded from Below by Gordon Creek Water Several Days Before.

This represents a maximum possible reserve for each of these lakes of practically 56 billions cubic feet, or a total of 168 billions cubic feet of water, which instead of rushing to waste, would be pent up in these reservoirs and gradually let out during the low period.

Taking the low period at 150 days between October and March, it will then be possible to augment ultimately the low water flow at Ottawa for that period by 10,000 to 12,000 cubic feet per second. It can be seen, therefore, what immense benefits will be derived from these reservoirs. Their beneficial effect is admirably resumed in Mr. Coutlée's report, as follows:—

1st. They will improve the potability of the water.

2nd. They will increase the depth for navigation.

3rd. They will increase and steady the flow for power production.

These reservoirs, though large, would not, however, be sufficient to exert the full control that is required of the flood waters during the extreme years of flood flow, and further reserves may be had by other dams at the outlet of Lakes Turnback, Opasatika, Grand Lake Victoria, Birch, Barrière, Kakabonga and several other lakes on the main stream or on the tributaries, which are now under study, or will be investigated as soon as time and staff are available.

In relation to the reserve dams, the one at the foot of Lake Temiskaming and that on Kipawa River are under contract.

The progress of the work on the Timiskaming dam has not been as rapid as was desired and expected on account of heavy work in foundation. The Kipawa River dam is progressing satisfactorily. Both dams are of concrete with stop-log sluiceways, having an aggregate clear discharge sectional area at least as large as the original section of the river.

At the commencement of the fiscal year, $41,760 had been expended on the Timiskaming dam construction and a year's time. As stated in the last annual report, no adequate plant or force was employed on the contract at the commencement, so the summer of 1909 was lost. It was January, 1910, before a steam excavator began work, and February before concrete laying commenced.

The cold of this northern section created difficulties in excavating and concreting that had only been overcome when Timiskaming Lake, responding to a very early spring, flooded the foundations.

When driven from the base platform, however, the force was turned upon the island abutment, which was brought up to full height in May, 1910.

During June, new coffer dams were built across the Ontario channel and the section between pumped out by the 25th. This steam shovel resumed excavation and operated during July and August, but stopped for good during the first week of September with work still to finish. In May, two meetings with the contractors were held to discuss programs for hastening the work.

A couple more conferences were held in June, the hardness of the excavation and the unforseen difficulties of unwatering being discussed. With an active manager, a good scheme and better rate of progress were achieved during July and August, 1910; but this, the third, manager leaving at the end of July, the work became disorganized in a month. The time for completing the contract was extended from 22nd July to end of December, 1910.

Concrete.—When the foundation pit was pumped dry, 25th June, 1910, the concrete was found in good condition, although laid during the winter and flooded before the sun could hasten its set.

By the first week of July, forms were erected to half height for seven piers and concreting was resumed on the platform and aprons. A good speed was attained, and during August the most work was done, although the firm changed their manager on the first of the month.

In September, the concrete work on the Ontario sluiceways was finished and no more has since been done.

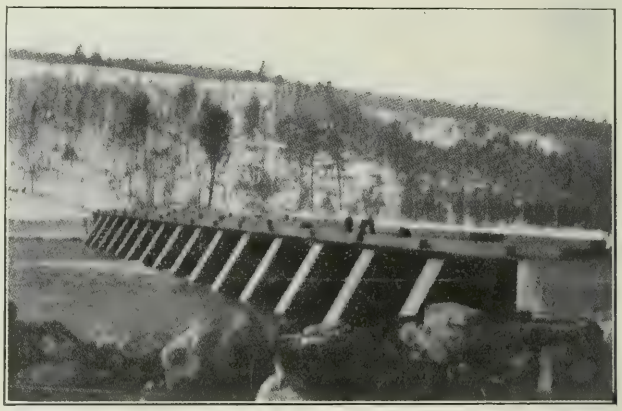

Fig. 3.—Timiskaming Dam. Ontario Sluiceways from Below, Showing Water on Lower Apron and Stop-Logs Piled on Roadway.

The piers and abutments are very fine samples of mass concrete work, the finish is good and the alignment particularly accurate.

The history of the concrete building in the Ontario sluiceways, during an unusually cold winter, is interesting.

Work began 12th February, 1910, and continued till April. Gravel of fair quality, but sandy, was the only available material and the mixing was done by machine. Large boulders were used as displacers in the concrete, each being thoroughly steamed to clean off ice before laying. The gravel and sand were stored in a bin that was heated by steam pipes and the water was also warmed. After laying, a movable steam radiator was set in place, and the mass covered with tarpaulins, so that all night the temperature was kept above freezing. The trench, into which the mixture, averaging 70° Fahrenheit, was placed, had, unfor-

tunately, hard frozen sides and there must have been a loss of heat to the frozen ground.

After being flooded with water at 32° F. for 70 days till 25th June, when the water was 55° F., the concrete was still soft enough to penetrate easily with a steel bar or pick. In 30 days, however, the mass was hard enough to resist repeated blows of a pick and only a few inches of the surface required to be removed.

The following gives an idea of the weather during one cold period in February, 1910:—

Record of Temperature.

1910	Day		Night	
	Maximum	Minimum	Maximum	Minimum
February 5	0°	-16°	-10°	-23°
" 6	-13°	-16°	-10°	-26°
" 7	19°	-10°	12°	26°

" 13	21°	-10°	20°	13°
" 14	31°	17°	18°	-18°
" 15	1°	-14°	2°	- 7°
" 16	9°	0°	2°	-22°

The chemical and physical action of setting is illustrated by the following temperature records of concrete built by the Department of Public Works at St. Andrews dam, north of Winnipeg in 1907.

A pipe with closed bottom and a screw top was placed low in the concrete, a thermometer being suspended inside from the screw top. As the wall or structure came up, additional lengths of pipe were added. For the sake of comparison the results in the accompanying table are given for three different parts of the work showing considerable range of condition of laying. In this table (A) is the pivot pier of lock, a heavy mass of concrete 35 ft. high and built in summer, during August, 1907; (B) is submerged dam, Span No. 1, winter work, January, 1908, working 11 hours a day, and (C) is submerged dam, Span No. 4, winter work, January, 1909, working night and day.

No doubt, the Timiskaming concrete rose in temperature at some stage in setting.

For winter work, a new practice is to use very quick setting cement that hardens before it is cooled below chemical action temperatures. Work of this kind was done on the power plant near St. Timothee, Que., during this same cold winter of 1910. By mistake, a car of the quick setting cement, made at the International Works, Hull, Que., came to Timiskaming. Its hardening was so rapid that its surface could scarcely be smoothed over. The first batches being especially troublesome, because nothing of the kind was expected. The result was apparently as good concrete as any laid, however.

Designs of Sluiceways.—Plans and views of these sluiceways are shown in Fig. 5. The sill platform is at elevation 570, or 19 feet below standard level of reservoir. It would have been preferable to have the sill 5 feet lower, but the excavation necessary to cut down the approach channel would have doubled the cost.

Between the island and Ontario shore, the width was about 400 feet, so the design was made for 16 sluiceways each 20 feet wide with a pier 5 feet wide between. The piers have recesses to hold a movable curtain wall formed of horizontal timbers, 18 inches square, that can be hoisted out one by one. This is a removable dam and during spring floods all the timbers will be lifted out, leaving a larger exit than under natural conditions, because the Ontario channel has been deepened. To draw off the lower layer of storage during March, however, requires deeper sluice openings, and so advantage of the depth in the deep Quebec Channel was taken to place those sills at elevation 565, or 5 feet lower.

Minimum Discharge at Timiskaming Sluices.—The minimum through Timiskaming should be about 20,000 c.f.s. and lake surface must be 573.95 to discharge the total amount as shown by the following calculation made by H. H. Donnelly, assistant engineer:

Taking 572.1 as elevation of water below Timiskaming dam for a discharge of 20,000 c.f.s., then:—	
16 Ontario sluices, each discharging with 0.95 feet head and 2 feet submergence at the rate of 20.5 c.f.s. per foot of crest, total 16 x 20.5 x 20	6,560 c.f.s.
13 Quebec sluices, each discharging with 0.95 feet head and submergence at the rate of 52.5 c.f.s. per foot of crest; total 13 x 52.5 x 20	13,650 c.f.s.
	20,210 c.f.s.
If the Ontario sills were as low as the Quebec side, then, with Timiskaming lake surface elevation 573.05 and the surface below dam elevation 572.1, the discharge would be:—	
16 Ontario sluices, each discharging with 0.95 feet head, and 7 feet submergence at rate of 35 c.f.s., total	11,200 c.f.s.
13 Quebec sluices, each discharging with 0.95 feet head, and 7 feet submergence at rate of 35 c.f.s., total	9,100 c.f.s.
	20,300 c.f.s.

As designed, the lake surface can only be drawn down to elevation 573.95, instead of elevation 573.05, so a layer 0.9 feet thick is rendered unavailable.

As before stated, however, lowering the Ontario channel would double the cost which is not warranted at present.

Foundations.—The foundation of the sluices is shown in Fig. 5. It consists of a concrete platform, 3 feet thick, strong enough to support a pier, if undermined during a flood, till repairs could be made. To prevent under scour,

a cut-off is made 10 feet deep across the upper face and another 5 feet deep across the lower side. In addition, a concrete apron, 25 feet wide, protects the bottom from scouring under the driving water at entry, and a 50 foot wide apron below prevents wearing away of material by the rapidly leaving flow.

The Ontario bed is boulder strewn with hard material beneath, but the work done in the Quebec channel, before the cofferdam failed (May, 1911), indicates a sand, hard, but easily saturated. Through this material, the seepage

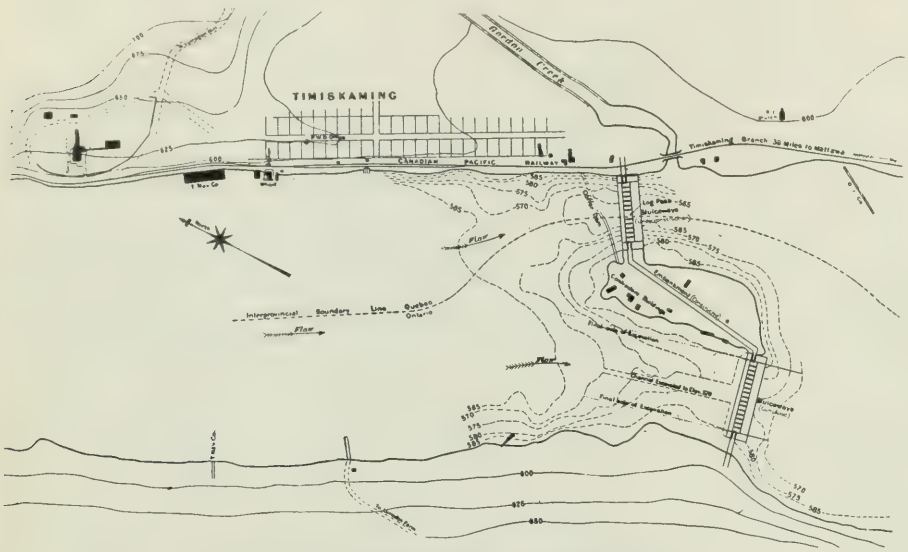

Fig. 4.—Plan Showing Timiskaming Regulation Works.

was all that four large pumps could conveniently manage. The foundation for the Quebec side will consequently be modified and include sheet piling beneath the cut-off wall. In fact, it proved impracticable to excavate the cut-off trench 10 feet deep in the sand, although the boring pipes were broken in piercing the undisturbed bed.

The depth to which a cut-off should extend in sand is debatable, but accepted practice is to go as far below the bed as the water surface is above.

Head water will soak the foundation, but cannot move the sand so long as it is boxed in or held by friction. If head water penetrates beneath the dam, then it buoys up the sand below and the tail water carries it away so rapidly that a cellar is formed.

Cofferdam, Quebec Channel.—After the middle of September, 1910, practically all the work was in connection with the cofferdam across the Quebec channel.

The type decided upon by the contractors was stone filled cribwork sunk to place and sheeted along the upstream face with plank. Round timber was procured from the Hawkesbury and Edwards limits near the work, and by the 17th October, the dam was half way across (210 feet). It was intended to unwater only half the channel and about 30 feet of cribwork was built down stream, but heavy rains caused an unusual rise of 5 feet and work had to cease. This brought most of the work on the dam to a stand-still, but sand was hauled and stone crushed which still remain stored upon the ground. The cable way was moved to the Quebec channel and put in working order by the middle of November, thus obviating the use of scows to cross material to the island. With a view to laying concrete during cold weather, arrangements were made to build a shed, 400 long and 60 wide, enclosing all the piers. Lumber was delivered for this, but owing to delays with unwatering, the shed could not be erected

To ensure immediate excavation of the foundation, orders were given to bring the steam shovel across the island. This machine had been left in the water since the Ontario cofferdam was cut in November.

Excavation continued in the island abutment, but leakage from the river through the fine sand stopped work several times, although a sheet pile bulk head was built, and a steam pump installed. Slips constantly occurred from the sides of the pit till finally, on 20th November, the river side burst in, when the excavation was to grade and only the cut-off trenches remained to be dug.

Lake Timiskaming continued extraordinarily high for the season, although the Kipawa River flow was shut flow was shut off by the Department's dam at that place. On 18th November, the Ontario cofferdam was blown out and the lake surface began to fall 2 inches per day. This had not been opened before, because the contractors were tendering for the excavation in the channel. The current soon scoured out between the south end of the dredge cut and the north end of the contractors' work passing a good flow through the sluiceways for the first time.

It was January, 1911, before the cofferdam was put under way again, when it was raised about two feet and track laid on top to carry stone filling and other material.

The lake had by then lowered three feet, so with a falling river, it was decided to cofferdam the whole channel and cribwork was begun from the Quebec shore. The advantage is that this method allows the foundation slab and cut-off walls to be built without joint. With a cofferdam half way across, the part parallel to the current requires to be a double crib with clay in the middle. Otherwise, the current will scour away staunching material from the exposed face, and in this case a boulder bottom prevents the driving of sheet piles.

An inexperienced force, cold windy weather, and the swift current made crib setting very slow and several cribs were lost by upsetting or breaking away of tackle.

By the first week of February, the new cribwork was connected to that built in October, and by the middle of the

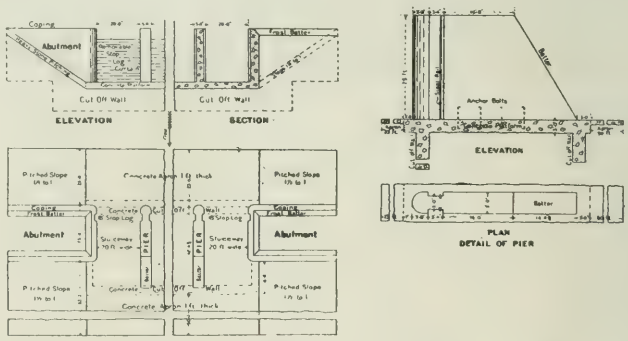

Fig. 5.—General Drawings of Concrete Sluiceways.

month the upstream face was sheeted with two thicknesses of boards. Large boulders upon the river bed made it difficult to closely fit the cofferdam to the bottom and cribs sometimes came to rest with one corner tilted over. No trench was dug in the river bottom into which to bury the ends of the face plank, because a diver could not work in the strong current. Instead, a bank was deposited along the front of the cofferdam, but the only earth available was fine sand that made a slurry in water.

The counterdam, across the lower end of the foundation area, to defend the pit from the lower pool, was finished by the end of February. There were only two small steam pumps, a six-inch and four-inch, on the contract and these could not lower the water below the lower pool, down to which it had run off naturally. Two large steam pumps, a twelve-inch and a fourteen-inch with boilers, were then rented and a pocket dam built just below the main dam. This was to intercept and collect the leakage which was led in box flumes over the work and emptied below the counterdam. The pocket dam was first a small earth bank, the sandy soil alone available, however, dissolved beneath the water, but froze hard in the air, bridging and obscuring leaky places. A sloping dam of planks, pointed and driven like sheet piling, was made but still the leakage kept the pumps fully engaged and water constantly burst beneath. Two more large pumps were added during March and every effort made to staunch leaks. It was not till the end of the month that four large pumps, working day and night, could keep the pit unwatered.

Meanwhile the spring rise was approaching, and to meet it the main cofferdam was raised 7 feet with continuous cribwork, which was filled with stone, adding weight to that already built. The cofferdam was of light section, but was well strutted on the down stream side. It was a question, whether stop-logs should be provided in this upper portion, but to arrange for them was difficult, and they could only pass 4,000 c.f.s., 5% of the flood. It seemed better instead, to blast out the Ontario side and increase by loosening and scour the space through which to get discharge, while the cofferdam blocked the Quebec channel.

The enlargement of the Ontario side by blasting and scouring was quite successful and aided the discharge greatly

Excavation in the Quebec foundation was possible during the last week of March and continued till the end of April. The lower pool then rose over the counterdam and operations had to cease, the plant being nearly all removed. On 4th May, the main dam failed by scouring under the Quebec end. The water was then overtopping it more than a foot.

Ontario Channel Excavation.—The dredge Queen excavated in the channel during the autumn of 1909 and encountered much difficulty from boulders upon which the scows and tug frequently grounded. After work stopped for winter, a force of drillers was kept on to blast boulders over the ground to be dredged during 1910. Low water aided this, and half the approach channel had been well prepared for dredging and some excavation had been swung out with the derrick by the end of March, 1910.

It was 17th May, 1910, before the dredge started, and after making one cut the dipper arm broke 18th June, then teeth were removed, so before repairs were finished it was 5th July. The material was so hard that it had to be blasted at times and low water prevented through cuts being finished to the contractors' work. The autumn rise, however, aided matters and a cut was fortunately carried to the cofferdam before work stopped in the middle of November.

The blasting of surface boulders was continued all season by a small force with good results, and when the cofferdam was cut 18th November, a good opening quickly scoured to the already excavated sluiceway channel.

Item	Unit	April	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Jan.	Feb.	Mar.	Total

Value of Contract Work in 1910-1911 on the Timiskaming Dam.

During March, 1911, a force was placed blasting the material along the edge of the Ontario channel. The loosening allowed the current to scour the material and a large amount was quickly removed, increasing the flow way against the rising lake which was troubling Haileybury and New Liskeard.

Dredging.—The Department dredge "Queen" resumed work in channel on May 15th, 1910, and was taken off for the winter November 15th. The total excavation during this time was 6,150 cub. yds. scow measure. The dredge is too light for the work and has been in service for eight years, consequently, there were many breaks, and time taken for repairs was usually large. The total length of time on the work was 1,557 hours, viz.:—

Actual working time	870 hours	55.9%
Lost time, repairs, etc.	592 hours	38.0%
Lost time Saturdays cleaning up and fueling	95 hours	6.1%
	1,557 hours	

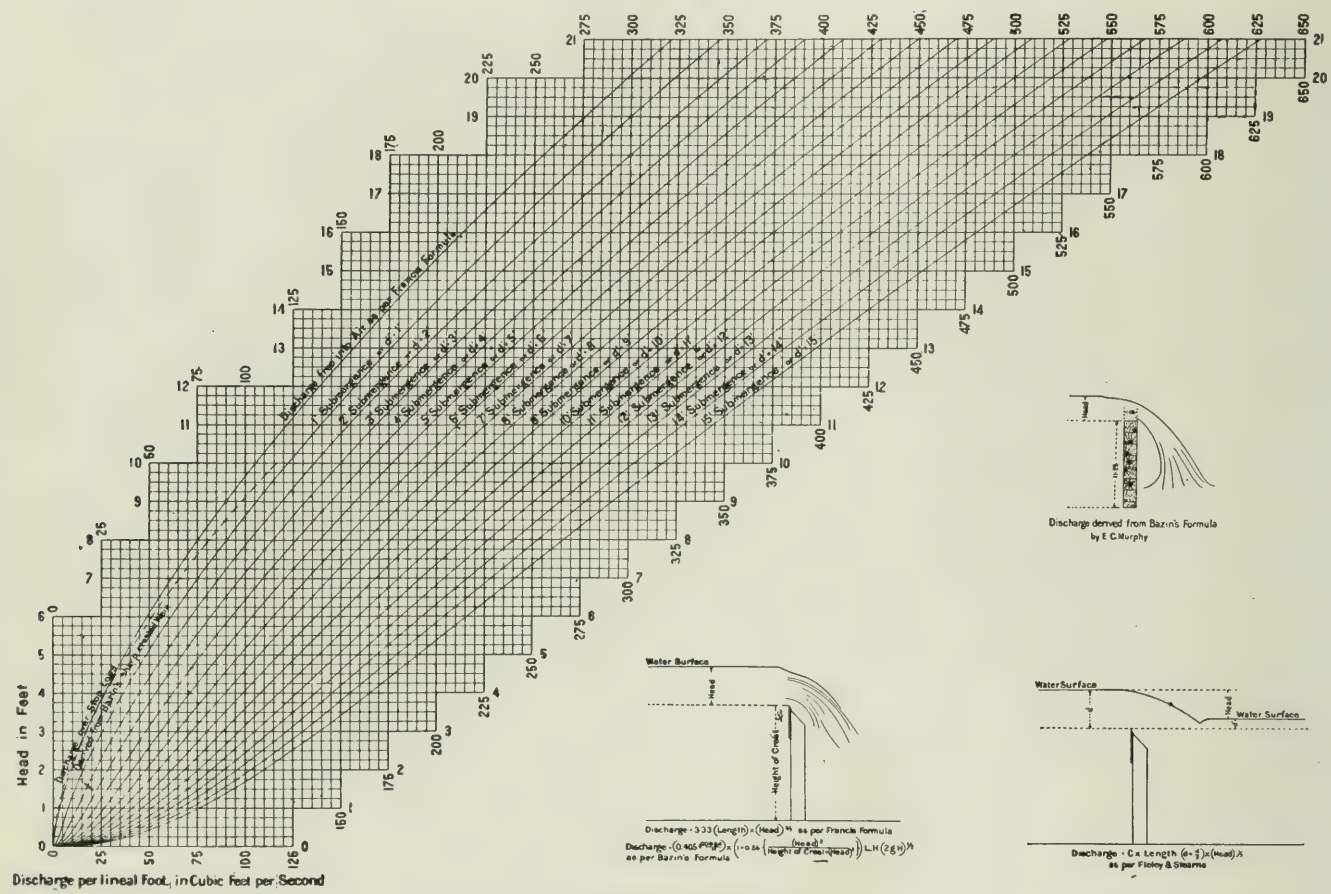
To open a channel through to the shovel cut excavated by the contractors, some work was performed lifting boulders. The dredge was also obliged to work in shallow water, where scows could not be used, and the excavation was taken away with a hand derrick. The extra labor cannot rightly be charged to drilling. The accompanying table shows the quantities and cost.

Summary of Cost of Drilling.

From October 6th, 1909, to November 30th, 1910.

Wages	$14,297	
Plant and accounts	6,863	$21,160
Less		
Clearing boulders to open channel	$840	
Taking away excavation from dredge to open channel, not chargeable to drilling	372	1,212
Net amount expended on drilling		$19,948

Area of channel drilled and blasted was 22,280 sq. yds., costing per sq. yd. of surface 89½ cents.



Head in Feet
Discharge per lineal Foot, in Cubic Feet per Second
Discharge derived from Bazin's Formula by E.C.Murphy
Water Surface
Head
Height of Crest
Discharge = 3.33 (Length) × (Head)^3/2 as per Francis Formula
Water Surface
Head
Water Surface
Discharge = C × Length (6 + 3/4 H) × (Head)^3/2 as per Fteley & Stearns

The Flow Over Weirs.

(From Report on Ottawa River Storage, Issued by the Department of Public Works, Canada).

The area of channel dredged in season 1909 was 583 sq. yds. During season of 1910 the area was 1,734 sq. yds., making a total area of 2,317 sq. yds.

Profiting by high water in November, 1910, the dredge was able to excavate close to the Ontario cofferdam, and when it was opened the water cut through between the contractors' shovel cut and the dredged channel.

Drilling and Blasting.—On March 1st, 1910, the area drilled and blasted was 7,700 sq. yds., since then 22,530 sq. yds., making a total to November 30th of 30,230 sq. yds.

Two No. 42 Little Giant steam drills were used for drilling on shore. Submerged work was drilled by hand from floats.

Area dredged, season of 1910, 1,734 sq. yds., which, at 89½ cents, cost for drilling $1,551.55.

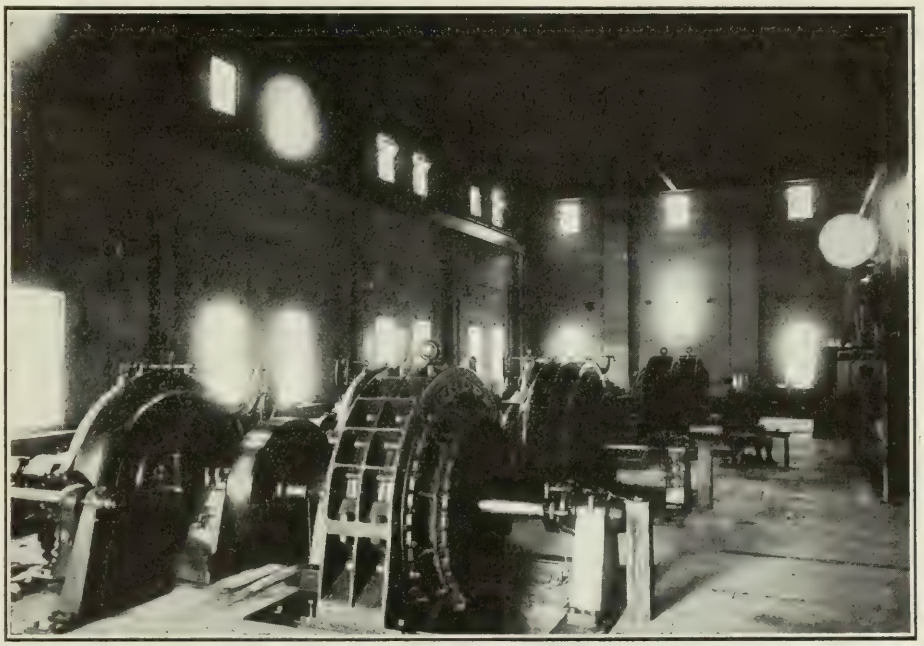
Dredged during season of 1910	6,156 c. yds.	
Cost of drilling per c. yd.	$0.175	
Cost of dredging per c. yd. (dredge $5 per hour.)	$1.268	
Cost of excavation	$1.443	per c. yd.
Cost of drilling operations, including removing boulders from channel, etc.	$0.187	
Cost of dredging	1.268	per c. yd.
Cost of excavation	$1.455	

POWER DEVELOPMENT IN COBALT.

By C. C. Bateman.*

In 1904, the rich silver mines of the Cobalt district were discovered, and while at first, believing that the deposits were not extensive, development was on a very limited scale, the camp gradually grew in size and importance, until it now occupies third place among the silver-producing communities of the world, the output being exceeded only by Mexico and the United States. During the year 1911 the output was approximately 33,000,000 ounces, and the production for 1912 will probably be about the same. The camp embraces an area of approximately seven square miles, in which there are thirty shipping mines, besides several non-shippers, and fourteen concentrators.

The running of mining machinery for comparatively small plants, as most of those in Cobalt were, does not readily lend itself to economical operation. The distance of Cobalt from the coal-producing centres is great, and as it is an all-rail haul, the cost of coal at the mines is necessarily high, averaging between $6 and $6.50 per ton. As a consequence, coal generated power is costly. A series of tests, carried on at the different mines over a considerable period, established the average cost for the camp at between 150 and $175 per horse-power year.



Interior of Concrete Power House on Matabitchouan River, showing four 1875 K.V.A. Generators, each being direct-connected to a 2,750 h.p. Turbine.

Within a comparatively short distance of Cobalt there were several good water powers, and when it was seen that the camp was firmly established as an important producer of silver, and that there was no question as to its permanence, companies were formed for the development and distribution of this power on a large scale. Considering the small area and the large number of consumers, the district lent itself very readily to this scheme.

Among these companies was the Mines Power, Limited, now known as the British Canadian Power Company, formed by E. A. Wallberg and F. John Bell, of Montreal, which secured a valuable water power on the Matabitchouan River, about twenty-two miles distant from Cobalt. Permission was also given by the Government to dam several of the lakes above the falls, thus providing for a large storage capacity, and eliminating as far as possible, the danger of a water shortage.

The main power dam is 50 feet high at its deepest point and 860 feet long. It raises the water about 40 feet above its former level, and gives a working head of 312 feet. It is estimated that a total of 10,000 horse-power can be developed if necessary.

By means of an intake canal the water is diverted to two steel penstocks, each five feet in diameter, and 1,075 feet long. Two turbines are supplied from each penstock. These turbines are of the horizontal reaction type, consisting of a single runner in a spiral case. They have a speed of 600 R.P.M., and are rated at 2,750 B.H.P. each. The power house is a solid concrete fireproof structure, 57 x 105 feet, and is fitted with all the latest appliances. It is also equipped with a travelling crane for handling the heavy machinery.

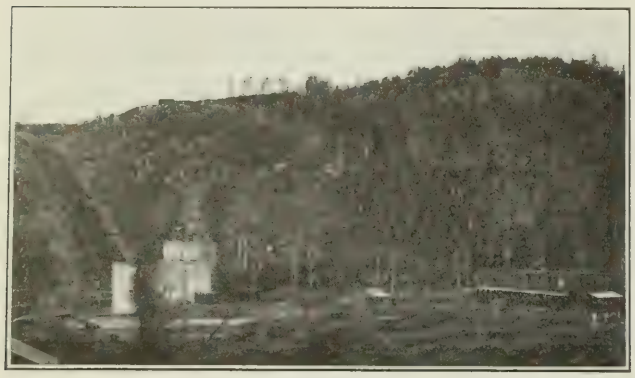
The electrical equipment consists of four alternating current generators, directly connected to the turbines, and having a capacity of 1,875 kw. each. There are two exciters, each directly connected to a Doble impulse water-wheel. These are rated at 180 horse-power, 475 R.P.M. High-power governors have been installed to ensure perfect regulation. The current is three-phase, 60-cycle, and is generated at a pressure of 2,200 volts. For transmission to the power stations at Cobalt and South Lorraine this potential is raised to 44,000 volts by means of step-up transformers.

There are two separate three-phase transmission lines, 35 feet apart, over a right-of-way 135 feet wide. The right-of-way has been entirely cleared, and, to further minimize danger of breakage, all tall trees on each side of the line have been cut down. The conductors are stranded aluminium cables, and the poles are equipped with high-tension porcelain insulators, which were subjected to the most severe tests before being used. The conductors on each pole line are of sufficient capacity to carry the whole load, thus eliminating the danger of a shut-down due to a break in the line. The whole system has, in fact, as far as was possible, been constructed in duplicate. The main transmission line is equipped with a private telephone system, and patrolmen are stationed at intervals.

For the distribution of this power to the various mines three brick and concrete substations have been erected. Two of these are at Cobalt; one at Cobalt Lake having a capacity of 5,500 horse-power, and one at Brady Lake having a capacity of 3,200 horse-power. The third station is at South Lorraine for supplying the mines of that vicinity. Each substation is equipped with all the necessary step-down transformers, lightning arresters, switching devices, etc. The electrical current is delivered to the customer at 2,200 volts, and by means of pole transformers is reduced to 550 volts for motor service, and 110 polts for lighting. Power is sold to the consumer on a flat rate of $50 per

* Mine engineer, The Dome Mines Company, Limited, South Porcupine, Ont.

horse-power year, or on a meter basis, with prices varying for the class of service and the amount consumed. While this rate is high in comparison with the rates for similar service in industrial centres, it is eminently fair, considering the high cost of such an undertaking and the shorter life that must be looked for in a mining district.



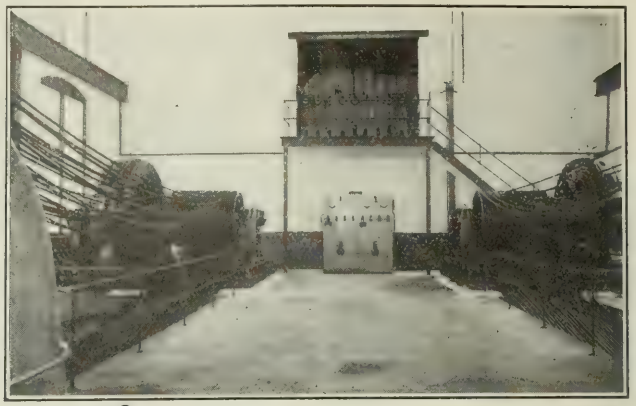
General View of Concrete Power House, Operators' Houses, Penstock Covering, Tail-race and Double Pole Lines to Cobalt.

An interesting feature of this company's power development is its system for supplying compressed air to the various mines. At both the Cobalt Lake and Brady Lake substations are identical compressor plants, each consisting of two two-stage air compressors. Each machine has a capacity of 5,000 cubic feet of free air per minute, and is driven by a 1,000 horse-power motor. This gives a total capacity of 20,000 cubic feet of free air. The compressors are equipped with the regular intercoolers, and each substation has installed an extra large water after-cooling system. From this the air passes through a large separator, and then through an air-cooling system. On account of the high temperature in the summer this latter system is only in use during the winter months.

Main Concrete Dam, 50 feet high, on Matabitchouan River, showing Timber Log Slide.

The air is delivered through steel pipes, with diameters varying from three inches to ten inches, and the two substations are connected by a ten-inch main. All the pipes are lapwelded, and the larger sizes come in 40-foot lengths. They are fitted with wrought-iron forged flanges, welded on, and each pipe has a weld in the cross section, made by the oxyacetylene process. They have all been tested to a pressure of 300 pounds per square inch. All fittings, valves, etc., are made of steel, and the pipes have all been coated on the inside with "Doctor Smith's Solution."

When the construction of these pipe lines was first under consideration, the question of expansion joints was taken up, but it was finally decided not to install them as



Two 1,000 horse-power Motors driving Compressors at Cobalt Station.

they were not considered sufficiently reliable. During a period of twelve months the extremes of temperature may amount to as much as 150 degrees Fahrenheit, and, in order to take care of the excessive expansion and contraction, the pipe lines were zig-zagged, and, although the plant has been in operation over two years, no trouble has yet been experienced.

There is at times in the pipe line a small accumulation of water, and, while this is not sufficient to affect the mines, it gave trouble by freezing in the winter time and stopping up the pipes. This difficulty was overcome by the application of an electric heater, the design of Mr. James Ruddick the former general superintendent of the company. At the lowest points of the pipes a ¾-inch cock is placed, so that the water will drain both ways to it. This cock is left slightly open all the time, and during the winter it is

View showing Ten-inch Pipe Line, with Electric Heater, 2,200 Volt Electric Pole Line, and 44,000 Volt Double Transmission Line, in Cobalt Camp.

kept warm and prevented from freezing by the use of the electrical heater. Automatic traps are being installed to take care of the accumulation of water in the warm weather

The air is delivered to the mines at 100 pounds pressure, and practically atmospheric temperature. The company endeavored to get high-pressure air meters, with the intention of selling the air at 24 cents per thousand cubic

feet of air compressed to 100 pounds pressure. These were found impracticable, however, and the air is now sold on the basis of $2 per drill per shift.

Two 1,000 horse-power Two-stage Air Compressors at Cobalt Station.

Operations in this plant were started in the first part of June, 1909, and power was first turned on March 17th, 1910, which is an enviable record for an undertaking of this size, considering the difficulties to be overcome.

As an evidence of the manner in which water development in Cobalt has succeeded in cutting down the consumption of coal, it may be stated that in 1909 the coal used in Cobalt amounted to 105,416 tons, while in 1910 and 1911 the consumption was 52,861 and 44,216 tons, respectively. Steam boiler plants are still in use for heating purposes, and the majority of hoists are still run by steam, so that a considerable quantity of coal is still brought into the camp.

AN ELECTRICALLY OPERATED LABOR-SAVING DEVICE IN LUMBER MILL.

The use of electrically operated machines in wood working plants has been the means of effecting many economies in their operation, so that it is not surprising to hear frequently of some new application of an electric motor in this industry.

The application illustrated and described herewith has proved to be so much more efficient in operation than the method it superseded that a description of it may prove of interest.

The apparatus consists of an automatic hydraulically operated door veneering machine installed in the plant of the Commercial Sash, Door and Blind Co., Beaver Falls, Penna.

This plant is most completely equipped throughout with individual electric motor drive, a total of 24 motors being used. Some are mounted on the ceiling and others on the floor in places most convenient for driving their respective machines. Those mounted on the floor are placed in enclosures to protect them from the dust and dirt such as is usually prevalent in plants of this kind. The veneer is placed on the door frames and when a sufficient number are ready they are placed in the compress as indicated in the illustration, which shows 110 1⅜ inch frames piled in five rows. Two sets of I-Beams are put in place one above and one below the frames, and turn-buckle clamps attached from one set to the other are tightened so as to hold the frame intact. After this has been done, the motor, mounted on the ceiling just above the compress, is started and the operator opens the valve which allows the hydraulic pressure to act. Gradually the carriage rises, compressing the frames until the pressure, as indicated by the gauge at the side of the machine, has reached the desired value. This value is usually from 1,300 to 1,600 pounds per square inch, depending on the nature of the wood to be compressed. A pneumatic safety valve automatically opens at any predetermined value, thus preventing any possibility of danger from excessive pressure.

It will be noted, on referring to the illustration, that the bottom portion of the compress is in the form of a truck. By means of this construction the material may be loaded directly on the truck which is then rolled to the compress on car tracks. When the desired pressure has been applied for a few minutes (about two, generally), the valve is opened; the pressure gradually relieved, and the truck returns to the normal position and is then rolled away.

As an example of the economy effected by this veneering machine, it should be noted that the time required for compressing is only about two minutes, while that required by the old hand-operated method was from four to five hours. With this method, the frames can be removed at once after they have been compressed, although it is generally customary to leave the clamps on for an hour or so, whereas in the older method it was necessary to have them on for several hours.

Automatic Hydraulically Operated Door-Veneering Machine.

The plant is equipped throughout with Westinghouse induction motors, taking current from the central station lines.

LUMBER PRODUCTION.

Two-fifths of the lumber of Canada is produced in Ontario, one-fifth in British Columbia, and one-fifth in Quebec; New Brunswick and Nova Scotia together make up the greater part of the remaining fifth, and but proportionately small quantities are manufactured in Saskatchewan, Manitoba, Alberta and Prince Edward Island.

THE COLLAPSE OF THE NEILSON BUILDING.

While an addition of three stories was being made to the Wm. Neilson Company's two-story chocolate factory on Gladstone Ave., Toronto, the south wall collapsed. Work commenced on the 28th March and the accident occurred on the 4th of May, when the wall was almost finished and part of the roof on.

As the plans show, the building was 90 ft. x 120 ft., and consisted of a basement and five stories. Mill construction was the type adopted for this building, and the rows of posts running east and west were spaced 14 feet apart; joists or floor beams, 5-in. x 12-in., 4 ft. on centres, spanned the 14 ft carrying three inch spruce flooring. This flooring was ploughed and a hardwood slip-tongue or spline used, and was securely blind-nailed to the Georgia pine joist. Duplex joist hangers were used throughout, and steel anchors every eight feet were fastened to the underfloor, i.e., over every other joist. Thus the beams ran east and west, the joists north and south, and the spruce underfloor east and west. The

View of Building After Collapse of Wall.

main beams were tied together with steel straps and the ends secured to the walls by wall boxes. From north to south during construction the tie consisted of the friction between the joists and hangers at the beam, and the rigidity of the floor platform, while the hardwood floor would complete the tie. The parapet wall of the old building (14-in. thick), was removed and the new wall started on top of the wall of the second story (18-in. thick). The new brick work, like the old, consisted of hard burnt clay facing brick, sand-lime lining brick with soft or salmon fillers laid up in lime mortar.

The old building was erected with the intention of adding two stories at some later date, and in order to satisfy to the city by-law, as part of a four-story building, the basement wall was made 22-in thick, and the first and second stories 18-in. thick. For the same reason the walls of the first story were designed to allow 30 per cent. of openings, while those of the second gave 40 per cent. Application was made, however, to the City Architect for a permit to erect the five-story building which was granted on condition that certain windows were to be blocked up to make the proper percentage of openings in the lower stories, and the first story wall was left 4-in. thinner than the City by-law requires.

In order that the Neilson Company might continue their business in the first and second stories, (in the old portion) the contractors agreed to arrange their work so as not to enter these stories and to hoist all of their material over the south wall.

For this work the bricklayers erected a double elevator hoist the full height of the intended structure, a couple of feet south from the street, staying it with guys. This hoist was operated by a small steam engine, and was so arranged that as a load went up on one platform the empty wheelbarrow came down on the other. This proved as it always does, to be a very efficient method of carrying the bricks and mortar. The carpenter had a gin wheel, with the fall passed through a snatch block made fast to a niggerhead, and a horse was then able to lift all the smaller material, including the 3-in. spruce flooring. For the heavier timbers there was a breast derrick mounted over the girder, nearest the south wall, with a 30-ft. boom which projected beyond the wall and as the timbers were swung over the floor they were lowered on trucks and wheeled to the required positions.

In order to permit of this hoisting the bricklayers left a section (some 30 or 35 feet long) of the south wall towards the western end open until the rest of the walls for that story was finished when they would fill this in. The carpenters would lay the new floor, raise the gin wheel and derrick to the new level and proceed as before. At the time of the accident the most of the roof and parapet wall was on, but this gap in the south wall on the top story was not filled.

The inquest was conducted by Mr. J. E. Elliott, who spent considerable time and took endless pains to make the investigation thorough, and the profession is indebted to the coroner and Crown Attorney Greer, for their efficiency in this matter.

It is a pleasure to see men in their positions anxious to get at the truth and at the same time sufficiently patient to listen to all.

The list of witnesses is a long one and may be classified as follows:

1. The medical experts.
2. Eye witnesses who were outside of the old portion of the building.
3. Eye witnesses who were inside of the old portion.
4. The contractors.
5. The architect of the building.
6. The city architect and staff.
7. Expert witnesses.

The medical expert testimony our readers are not particularly interested in, so that we will begin with the second class, viz., eye witnesses outside of the old building.

Of these examined was John Sole, who was the engineer in charge of the bricklayers' hoisting engine. He was at his post at the engine a few feet south of the centre of the south wall facing west and said that about 10.30, he heard a noise as of wood tearing and on looking up he saw some bricks falling about 30 feet behind the boiler. He fixes the position of the first failure very definitely as east of him i.e., the eastern part of the wall and towards the top. Several of his answers are very definite and full of information—"Gradually opened at the top and collapsed right straight down"—"The whole tearing was on the east side and it fell down and collapsed in a heap." "Did not fall out whatsoever, simply opened and collapsed."

Q. "How long did the whole break take from the time you first saw it until the finish?" A. "About a minute—it fell very slowly for a wall." Q. "Were the bricks thrown far to the south?" A. "No, I think about 30 or 35 feet." Q. "Your engine did not explode?" A. "Oh no, did not explode whatsoever." As this was the only boiler in addition to

that supplying the factory with power and heat and which is still in good condition, in the immediate neighborhood of the building, it settles the theory proposed by the Assistant City Architect, that the accident may have been due to a boiler explosion.

Chas, Watman, a foreman for the Bell Telephone Company, who was working about 300 feet south of the building and had almost an unobstructed view of the fatal wall said, "I heard the noise and then I thought, silence and I could not hear anything. I thought it was inside, something falling; just sounded like as though it was a big timber or some lot of bricks had fallen." Q. "Perhaps what you heard was the first few bricks Mr. Sole speaks of." A. "Might be—very great noise." "I think they hit some boards if I am not mistaken." He was too far away, however, to observe any of the details other than those already mentioned.

Robert Harion, a street railway conductor, was walking south on Gladstone Avenue, and said that a few moments before the accident they were using the derrick. He saw the boom projecting over the wall. This agrees with the evidence of the carpenters, that they were dismantling the derrick and at the time of the accident had the boom lying on the fifth floor projecting slightly beyond the face of the wall.

Jas. Foley, bricklayers' laborer, was wheeling material north on the fifth floor when he heard a noise, looked around and saw the wall falling.

Wm. Palmer, carpenters' laborer, was standing on the fourth floor, three windows from the west end. Q. "First thing that called your attention was the noise?" A. "Yes." Q. "Could you see daylight?" A. "No, but I could see her open a little and she wobbled like that." Q. "So then Mr. Sole's impression of what happened is nearly correct, the east end fell completely and dragged the west end after it?" A. "Yes."

Albert Hamilton, a bricklayer working on the west wall, heard a noise, looked around and saw the south wall disappear from view going down straight.

These witnesses and others agree that their attention was first arrested by a noise of considerable magnitude. That the first failure was in the upper part of the eastern end of the new wall, that it buckled and fell vertically. It might be added here that the coping was found near the base of the wall.

The only evidence our readers are interested in as given by those witnesses who were inside the old building at the time of the accident, may be summed up in the statement that they all heard a great noise, looked up and saw bricks coming through the ceiling and ran.

The evidence of the contractors, i.e., brick-work and carpenter-work went to show, that they had entered into the agreement for certain consideration to supply material and labor as called for in certain plans and specifications and so far as they were concerned they believed they had lived up to their contract to the satisfaction of the architect, the City Architect and Mr. Neilson. They could not account for the accident, but Mr. Wood said that he would never build a brick wall, using lime mortar, as fast again. They did not consider the vibration from the machinery in the building, nor that from the three hoists of any serious consequence.

The architect of the building explained the plans, and the method of working as already indicated, and further said that this factory was of ordinary and not mill construction.

In order to make it clear to our readers, it would be well to mention here that the by-law defines ordinary mill construction, slow burning, fireproof, etc., and according to their definitions, the Neilson building was not mill construction, because, first of all, the joists were not of 60 sq. in. sectional area; second, the roof boarding was under 2¾-in.; third, wooden corbels were used; fourth, there were a number of wooden partitions less than 2¾-in. in thickness. These, and a few other minor details certainly bear out the architect's classification.

The transverse tie of the building from wall to wall (north to south) was criticised by some of the witnesses and commented on by the press at some length.

In his evidence the architect explained that during construction the tie was as follows:—

Every joist (40 ft. on c.) rested on a duplex wall hanger which had a lug ¾-in. high, so that the joist would have a tie equal to the straining resistance of 3 x 5 sq. inches of Georgia pine. The bearing plate of the hanger was 5 x 9 inches, so that this tie to the wall was at least fair. At every second joist a wall anchor was made fast to the top of the three-inch spruce floor, making fastening number two from the joist to the wall. The other end of the joist rested on a duplex hanger without a lug, so that the tie there was frictional only. The main tie, however, as he explained, consisted in the fact that the floor system in the first bay, 14-in. wide, formed a rigid platform of 5-in. x 12-in. joist to which was securely spiked three-inch spruce flooring in long lengths, and broken joists well fastened to the wall. He further pointed out that when the hardwood floor which would run north and south, was laid, it would complete the system of cross ties. When asked his opinion of the cause of the accident he said he could not tell. There were a number of causes such as vibration, handling material over this green wall, but none of them, nor all of them together, were sufficient, in his opinion, to cause the collapse. It was possible, however, that in handling some of the heavy timbers the wall had received a blow which would weaken it and finally cause the trouble. He said that he was well satisfied with the materials and workmanship of both contractors.

The City Architect in his evidence stated that he had issued the permit for the alteration, claiming that when the windows mentioned before were blocked up, the building would conform to the by-law. It would be well here to look at the reading of the by-law regarding the thickness of walls. Section 22, page 39 reads as follows: "The walls of all brick buildings shall not be built of less thickness than called for in the following tables." The table referring to this building gives the following thickness: basement, 22-in.; 1st floor, 22-in.; 2nd floor, 18-in.; 3rd floor, 18-in.; 4th floor, 14-in.; and 5th floor, 14-in. Sub-section 2, page 44, reads: "In the foregoing tables of thickness of walls the perpendicular distance from the top of joists in one story to the corresponding point in the next story is to be understood to mean not more than 12 feet in the basement or cellar, 19 feet for the first floor, 16 feet for the second story, and 15 feet for each for all stories above the second except the top story, which may have an additional 5 feet in height at the highest point. If any single story exceeds these respective heights the walls of such story and all the stories below the same shall be increased ½-inch, or about 4½ inches more than the thickness given in the tables."

Now, in his evidence the City Architect granted the permit knowing that the walls of the first story were only 18-in. and not 22-in., as required by the tables in the by-law, because the walls were old and well set and because the heights of the 1st, 2nd, and 3rd stories, when taken together, did not exceed the limit as set by the by-law. You have but to look at the wording of the by-law to see the very careless interpretation placed on it by the guardian of the public.

To him the collapse was a mystery because the materials used were excellent, the workmanship good, and the work regularly inspected, though not as frequently as he would have liked.

F. H. Sykes, of the Department, identified the plans and specifications of the building as those which he had pased through the office, and presented an elevation of the south wall, as it was just prior to the accident. The plan showed the windows that were to have been blocked up and gave a list of the loads per square foot on the various piers.

Mr. Tice, the inspector of the dictrict and Mr. Price, the Assistant City Architect, also gave evidence. Among other things, they said that the building rested on virgin soil and nor made land. That the foundation walls went down some 8 feet and were still in good condition. That the materials used were perfect, the workmanship was first class. To them, as to their chief, the cause of the failure was a mystery.

A most remarkable statement was made by the Assistant City Architect, viz., that the floor load which would be placed on the wall by the hangers which went 5-inches into the wall would be distributed uniformly through the wall by the bonding courses. That after some four or five courses this would not be an eccentric load.

The Expert Witnesses.—R. Marshall, a demonstrator at the School of Science, made a number of tests in the different materials used throughout the building and pronounced them all as good.

Mr. Newall, an experienced builder, examined the ground and pronounced it virgin soil. He also stated that he had plumbed the walls left standing and said that they were plumb and true and that the posts were also plumb.

Robert W. King, a civil engineer, stated that in his opinion the wind blew the south wall out, and that the tie was not strong enough to hold it. The report of the weather as obtained from the Meteorological office, shows that at the time of the accident and for several days previous to it the wind was only a gentle breeze from the east or south so that this theory must be dispensed with.

He also criticized the use of wooden corbels and even though they had nothing to do with the failure of the wall, the point is well taken and in our opinion the by-law section 45, page 97, should be amended so as to include other kinds of construction as well as mill.

The section reads, "If wooden posts are used in **mill construction** they shall have cast, wrought-iron or steel caps of an approved pattern, so constructed as to form a base for the next post above." Certainly the words "mill construction" should be dropped from this by-law.

Prof, C. H. C. Wright, of the University of Toronto, in his evidence stated that he believed the building rested on virgin soil, that the foundation walls were in good shape, that the failure did not start in the old walls and that therefore, the failure to block up the windows in the old wall as required by the department, had nothing to do with the failure. The theory had been advanced by some that the swelling of the 3-in. spruce floor had pushed the wall out. But as he said, this wood went in wet and would shrink rather than swell, and as the boards were nailed on one side, the only effect of shrinking would be to open up cracks between the boards. He claimed that as the openings in the north wall were similar to those in the south it was absurd to talk of the wind forcing a pocket and blowing the south wall out. He agreed with Mr. King that where a system of wooden posts and girders are used, wooden corbels should not be permitted. It was a system that was gradually being done away with and he felt that the city of Toronto might reasonably prohibit their use.

He said that the transverse tie of the wall was sufficient during construction and with the hardwood floor laid, satisfactory.

He said that he considered the vibration from the light machinery in the old building was negligable, but that was due to the handling of the materials over the south wall of the three systems would retard the setting of the mortar. He pointed out that the base of the smaller piers in the fourth story, as the weak spots in the wall. The windows are arranged in groups of three with two small piers between them, while those between the groups are larger. The measurement of the piers on the inside between the wooden sills is two feet, while on the outside it is three, and the offset occurs a half inch back from the face of the wall which is 13½-in. thick.

At this point he stopped to explain that the authorities were often misguided in reference to the strength of brickwork, and masonry. The failure to classify brickwork properly and to distinguish between the piers as built in the laboratory and those built commercially were the reasons for much of the trouble. In the laboratory every brick is selected, they are thoroughly wetted, laid frog up, with even joints of from ¼-in. to ⅜-in. thickness, joints perfectly filled, etc.

To make allowance for this difference, Kidder and other authorities place the **safe** loan on brickwork masonry of hard burned clay brick laid in lime mortar at from 5 to 7 tons per square foot.

The wall under consideration was built of hard burned brick for facing, a good sand lime brick for the inner surface, and a soft brick filler. The bricks on the inner side were smaller than those on the outside, and hence the joints on the inside were thicker than those on the outside. The inside of this wall was therefore, weaker than the outside. The bricks were laid frog down thus losing one-third of the bearing area of the brick. (It is only fair to say here that this is quite a common practice in Toronto).

In his opinion the safe load on this brickwork is five tons per sq. ft. when set. As these piers were only from two to three weeks old, he felt that the safe load on them was not over half the safe load when set.

The weight of the floor and roof without considering any load on either, gives a load of 1,000 lbs. acting 2½ inches in from the inner face of the smaller pier, while that due to the brickwork was 13,000 lbs. acting at the centre of the pier. This gives a stress of between 3.5 and 3.75 tons per sq. ft., which he considered to be beyond the safe stress in these green piers; and whenever a load beyond the safe limit is used a chance is taken. These piers were weaker on the inside than the outside and under this loading they buckled and fell.

Speed, then, was in his opinion, the main cause of the accident. When asked about the material used he said that the materials were all good and the workmanship quite satisfactory.

It might be added here that by insisting on a better classification (i.e., not permitting hard surface brick with soft cores to be classed as hard burned brick) and a more rigid inspection, many cities have raised the safe load for hard burned brickwork with lime mortar, to, from 8 to 9 tons per sq. ft.

In summing up the evidence for the jury the coroner gave a very fair review of the facts as brought out by the investigation. The finding of the jury will, we are sure, prove to be very satisfactory to the profession. It will be agreed that recommendations Nos. 3 and 4 are good, but that Nos. 1 and 2 are weak.

The following is the finding of the jury:—

"It is the opinion of this jury that the collapse of the south wall of the Neilson building was due to a combination of circumstances.

Causes:—

"(1) Vibration caused by the working of the gin wheel, bricklayers' hoist, derrick and machinery in the occupied portion of the building, retarding the setting of the mortar."

"(2) Strain caused by the hauling of all materials over south wall while in a green state."

"(3) The green wall had the load put upon it before the mortar had time to set."

"(4) The above combined with a possible cause set as a jar or shock which the wall may have received while in a green state."

Riders:—

"(1) We are further of the opinion that walls of this height and length should be built of pier construction."

"(2) That in the construction of a building of this type a temporary tie should be used while under construction."

"(3) That buildings of this dimension should be more frequently inspected."

"(4) We would also suggest that cement be used for rapid construction."

When Coroner J. E. Elliott read over the finding, one juror rose to dissent to clause 3 of the causes. He wished it recorded that he did not think the wall was over-loaded.

Prof. Wright made what we consider a wise recommendation when, in his evidence he said that he thought the city should insist on having the staircase in every such factory building enclosed with brick walls or some other substantial fireproof construction.

It would also appear that Section 14, page 38, of the by-law is not enforced. It reads as follows:—"No pier buttress or pilaster shall be built in freezing weather, and all brick in such piers shall be laid frog up and pushplaced or grouted at each course." As Prof. Wright says, why not have bricks always laid frog up and get the bricklayers into a good habit?

GOWANUS CANAL PUMPING PLANT.

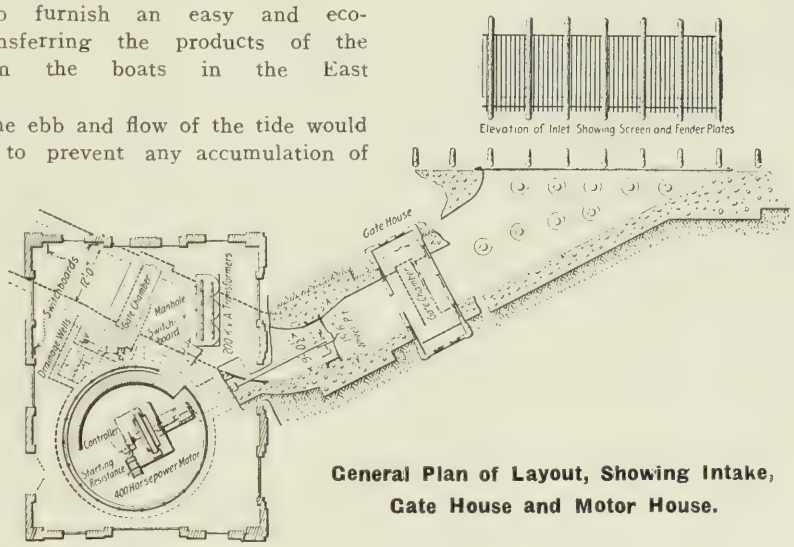
When the Gowanus Canal was constructed in Brooklyn a number of years ago it was heralded as one of the greatest engineering feats of the age.

But it was not long before the engineers were confronted with a serious problem which it has taken thirty years to solve; and only then through the aid of electricity.

The canal was built from the river, through a devious route to a point in the heart of the manufacturing portion of the city, and there dead-ended.

Its purpose was to furnish an easy and economical method of transferring the products of the shippers to and from the boats in the East River.

It was thought that the ebb and flow of the tide would cause enough circulation to prevent any accumulation of impurities which would be disagreeable or unhealthy. A large amount of surface water was drained from the streets and emptied into the canal through sewers, but due to increase of population and manufacturing industries, which are continually depositing waste matter in the canal, the water became most foul and unsanitary. It was also found that the action of the tide had little or no effect in removing the waste matter. This was especially true at the dead-end of the canal, where the stagnation was excessive. The odor was so foul that it could be detected for blocks around, and was so detrimental to the public health in that community that drastic measures were taken to effect more sanitary conditions.



General Plan of Layout, Showing Intake, Cate House and Motor House.

Finally, the city engineers decided on flushing the water from the dead-end of the canal into the river, where it would be carried away by the action of the tide. To accomplish this it was decided to install a screw propeller pump, which would simply pull the water along in the same manner that a propeller pulls a ship against the resistance of the water; in this case, however, the propeller being stationary, the water is forced to move. It was first proposed to employ steam to drive the pump, as had been done on one or two similar installations made in other places, but the engineers soon saw the advantages to be had by employing electric drive, and lost no time in convincing the city authorities of the advantages, and so an induction motor was selected.

The result was the removal of all the filth and polluted waters from the canal and a clean, healthy atmosphere now prevails. Property value in the immediate neighborhood which, under the old regime had sunk to almost nothing, has now increased to its proper value.

The motor and control apparatus are located in the circular pit 24 feet in diameter and 29 feet deep, built under the pump house.

The motor is rated at 400 h.p., and runs at 120 r.p.m. with full load, enabling the pump to deliver 30,000 cubic feet of water per minute. It is located 56½ feet from the propeller, to which it is connected by a shaft eight inches in diameter. The propeller consists of four blades having a pitch of 5 feet 6 inches, and the shaft runs through a water-cooled thrust bearing.

The tunnel is 12 feet deep and 50 feet wide at the canal but narrows down to 9 feet at the propeller, thus allowing ⅛ of an inch clearance for the propeller blades.

This water is discharged into what is known as Buttermilk Channel through a sewer 6,300 feet long. An interesting point in this connection is the fact that the water moved by the propeller weighs 64 pounds per cubic foot, or 2½ pounds per foot more than the weight of pure water.

Electric energy is delivered to the plant at 6,600 volts and is stepped down by means of three oil-cooled transformers at 550 volts, at which potential it is supplied to the motor through a suitable switchboard equipped with the necessary motors and control devices. The motor and control apparatus were furnished by the Westinghouse Electric and Manufacturing Company, East Pittsburg, Pa.

GOVERNMENT DRYDOCK IN TORONTO

In our issue of July 27th, 1911, mention was made of a drydock that was to be constructed at the yards of the Polson Drydock and Shipbuilding Company. When it became known that the Federal Government would give financial aid to the project, Mr. Wm. Newman, works manager, visited

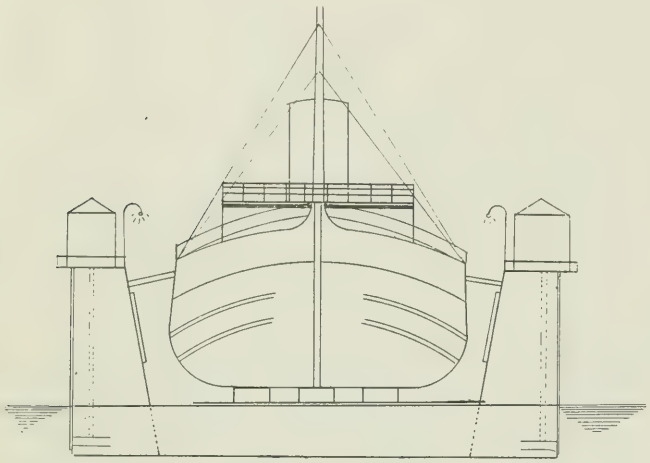


Fig. 1.—Section Through Drydock, Showing Vessel.

several drydocks in Europe and the United States with the result that the original plans and design were altered to a considerable extent.

The plan as originally laid out called for the construction of the dock in two sections, 150 × 100 feet each, and included arrangements so that the two docks could be merged into one resulting in a combination that would accommodate a ship of 4,500 tons and a beam of 80 feet. The new design calls for a structure 330'0" long: 100'0" wide: 35'4" deep: 72'0" wide on deck: 88'0" wide on top and 8'6" depth of hold: will weigh approximately 2,400 tons, with a lifting capacity of 5,400 tons, and will cost in the neighborhood of $392,000.00.

A reference to Fig. 2 will make the main details of construction clear.

The structure consists of one longitudinal watertight bulkhead amidships, and a transverse watertight bulkhead every 50 ft., dividing the dock into 12 equal compartments 50 ft. square, with a pump in each. All framing is transverse, 30 in. centres, and the plating is in excess of Lloyd's requirements. In addition to the longitudinal watertight bulkhead, there are six longitudinal lattice bulkheads, equally distributed, which, with the sides, insure absolute longitudinal rigidity. There is a transverse truss frame fitted every 10 ft. of ample proportions, which support the bilge block cross tracks. The bilge blocks will have a relieving screw under the top block, and will be of British Columbia fir which will have a certain amount of floating power and will be retained in position by underhung wheels enabling one man to operate them with ease.

There will be a joint in the centre of the dock composed of 6" x 6" x ½" angles riveted round the inside of shell, by means of which the sections are held together by 1¼" machine bolts every 6" with a rubber gasket between to make watertight. Butt straps 30" x ¾" are bolted all around dock at joint above light water mark. Rolling fenders are placed on the inside of dock at the ends to protect dock corners from boats entering and leaving.

Four ship's capstans are situated on the upper deck to handle ship's lines when docking. Another feature is the mooring device of the dock itself. An I-beam is riveted on the outside of the dock, perpendicularly, opposite each bulkhead, which are held in loose clips on the edge of the wharf allowing the dock to raise or lower, or list if necessary, without adjusting.

There will be compressed air, steam, and electric power conduit systems run on both sides of the dock, with manifolds every twenty feet for operating the tools. Sixteen arc lights are hung from the upper deck with plugs for drop lights every ten feet, which will permit of continuous work on the dock when necessary.

The only opening in the dock is a small hatch into each compartment from the upper deck, which, in case of accident, can be sealed and compressed air pumped in to expel the water.

One section of the dock can be used for docking the other section. This dock is large enough to take the largest and heaviest boat on Lake Ontario, which is the car ferry "Ontario No. 1"—317' 0", between perpendiculars, and 5,146 tons gross. The pumping equipment consists of twelve 12" centrifugal pumps with a capacity of 42,000 imperial gallons per minute, working in batteries of three in each quarter of the dock: each battery driven by a 75 h.p. D.C. motor, and all pumps being controlled from a central station ashore, which commands a view of the entire dock and is all handled by one man.

With this pumping equipment the dock may be emptied of water in twenty-four minutes. The equipment is entirely frostproof and is so designed that the absence of levers and piping is at once conspicuous.

There are twelve pumps, one in each section of the dock, which is divided by watertight bulkheads every fifty feet.

In order to get a site large enough to construct this dock, it was necessary for the Polson Drydock and Shipbuilding Co. to acquire the two water lots east of their present works, and they have been filling in all winter. The output of the yard will be in no way restricted as special plant has been procured from England to carry on the construction of this dock, which no doubt will fill a long-felt want in marine circles in the Port of Toronto. The structure will be located at the foot of Frederick Street.

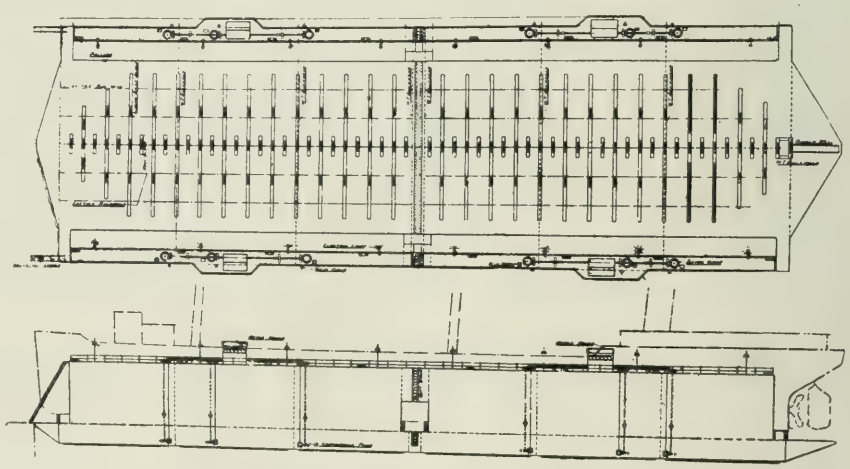

Fig. 2.—Plan and Elevation of Floating Drydock.

Sir Thomas Shaughnessy, of the Canadian Pacific Railway, has announced the intention of that company to double track their line through the Rocky Mountains, at a cost of $60,000,000.

STEAM TURBINE DEVELOPMENT.

The development of the steam turbine has been very rapid. Mr. A. G. Christie in a paper presented to the American Society of Mechanical Engineers recently, takes up the present state of development of large steam turbines. His view of the probable tendencies for the future are of interest and we present them almost in full.

Mr. Christie states that the cost of manufacture is a very important item in determining the future development of the steam turbine. Types such as the original Parsons and the Rateau, while inherently of very high efficiency, have too high manufacturing costs to compete with the newer combined types.

The writer offers as his opinion that the combined types, such as the Curtis-Parsons, the Curtis-Rateau, and also the Curtis-Rateau-Parsons, previously described, will very soon supersede the simple types. It is probable that the Curtis turbine will eventually be built only in horizontal units and will gradually be modified to a Rateau or even a drum impulse construction in the low-pressure sections. The freedom from close adjustment in impulse turbines and the recent improvements in blading materials will greatly increase the use of this type, although Curtis-Parsons turbines are said to be cheaper to manufacture. In actual operation, it is an open question among engineers whether the reaction turbine has a higher commercial efficiency than the impulse type, and hence buyers usually consider first cost and personal preference only.

Turbines will probably be made shorter with very stiff shafts. With this construction many of the earlier blading troubles will disappear. But the peripheral speeds will also be increased and this will involve the development of suitable blading material and methods of holding blades that will satisfy these new requirements. Recent results seem to indicate that improved efficiency may be looked for with increased blade speeds.

Several impulse turbines have been built recently in Europe where the expansion was not complete in the nozzle, so that a portion of the expansion took place in the first moving blades. Some large Curtis turbines recently installed in America are said to have Parsons blading in the last stage. These developments would indicate a movement to introduce reaction principles in impulse turbines, and further illustrate the tendency to merge types.

The hope of further improvement in efficiency lies in extensive study, particularly of the action of the steam during its passage through the moving and stationary blades, of the effect of form of blades, passages and casings and of various forms of baffles and balance pistons to prevent leakage. Such research work has not been carried out up to the present time by most manufacturers, largely on account of the extreme care and heavy expense involved in such tests. The present state of development has been largely one of cut and try. The increasing competition of the gas engine and the possible development of a satisfactory gas turbine will force manufacturers to develop their turbines to the greatest degree of economy.

With regard to detail, simplicity will be the leading consideration. With the introduction of Curtis high-pressure stages, nozzle governing will undoubtedly be used to an increasing extent, though the results obtained by Westinghouse, by Zoelly, and by Bergmann with simple throttling governors, raise a question as to whether the additional complication of nozzle governing will pay. Oil relays will probably replace all other systems of governing on account of their simplicity and reliability. The simple and efficient centrifugal oil pump governor of Sulzer appears to be an improvement of considerable moment, and will probably receive extensive use.

With the development of suitable gearing for steam turbines, their field of application has been greatly increased and turbines will shortly be used for purposes which engineers to-day would consider them utterly unfit.

Low-pressure turbines will continue to be installed in plants where reciprocating engines are still in operation and also where large quantities of waste heat are available. The low and mixed pressure types of turbines will find a very extended use in connection with heating systems, evaporators, etc.

The development of the past ten years has been truly marvellous. No great gain in thermal efficiency seems possible, so that future improvements will be largely along the line of detail construction and modification.

ADVANTAGES OF OIL AS FUEL.

In a recent discussion regarding the oil engine Mr. Wolcott Remington, the designer of the Blanchard Oil Engine, stated very clearly the advantages of oil as fuel. Mr. Remington stated that in general the cost of kerosene oils is approximately one-half the cost of gasolene, while the ordinary distillate and fuel oils may be obtained for about one-fourth of the cost of gasolene. He recommended that oil purchases be made direct from oil companies, as local retailers' prices are frequently twice as much as the former.

In the United States the total annual production of kerosene, fuel and distillate oils is about 6,500 millions of gallons, as against 720 millions of gallons of gasolene. Therefore it is fair to assume that the increasing use of internal combustion engines will not materially affect the cost of oils for a long time to come, since their production is so large and must continue to be so long as gasolene is used. On the other hand gasolene is continually increasing in price and becoming of inferior quality.

A most important advantage of kerosene and fuel oils over gasolene is their comparative safety. Kerosene is non-explosive and has a flash point of 150°F., or more. Gasolene, on the other hand, readily volatilizes at normal temperatures, and this vapor is not only very poisonous but is highly explosive when mixed with air. Insurance companies in many places permit the installation of oil engines where the use of gasolene engines is absolutely prohibited.

THE BEGINNINGS OF MONEL METAL.

About seven years ago one of the large smelting companies began investigating the chemical and physical properties of an alloy that had been reduced directly from nickel-copper matte without the previous separation of the two metals. This alloy was found to possess not only the valuable properties of nickel, but also other desirable properties in addition, that would insure a wide usefulness, and owing to the simple method of production, was obtainable at about one-third the cost of nickel. In 1905-6 the International Nickel Co. considering, no doubt, that for many purposes there was no need to separate the amicable metals nickel and copper, took up the problem of reducing them together and obtaining an alloy of the two metals in the proportions in which they occur in the ore. The alloy thus obtained was named Monel Metal, after Mr. Ambrose Monel, the president of the International Nickel Company.

This table may be used for any substance having the form of a hollow cylinder. If the weight is desired, all that is necessary is to know the weight per cubic inch of the material and multiply the values given in the table for a particular diameter and thickness of material and the answer will be in pounds per foot run.

Below are given values for a few of the common materials usually met with in the form of tubes:

	Wt. cub. in.		Wt. cub. in.
Wrought Iron Solid Drawn Tubes	.283 lbs.	Glass	.107 lbs.
Do. Lap Welded	.270 ,,	Do. Common	.091 ,,
Do. Boiler Tubes	.277 ,,	Platinum	.778 ,,
Cast Iron	.263 ,,	Silver	.378 ,,
Steel	.282 ,,	Tin	.265 ,,
Copper, Cast	.314 ,,	Zinc	.260 ,,
Do. Sheet	.322 ,,	Lead	.410 ,,
Do. Seamless	.329 ,,	Do. Composition 7 Lead, 1 Tin	.382 ,,
Bronze Copper 8, Tin 1	.306 ,,	Do. do. 7 Lead, 1⅓ Tin	.373 ,,
Brass, Cast	.297 ,,	Do. do. 7 Lead, 2 Tin	.363 ,,
Do. Sheet	.303 ,,	Do. do. 7 Lead, 4 Tin	.340 ,,
Aluminium	.092 ,,	Do. do. 7 Lead, 8 Tin	.315 ,,
Do. Bronze Al. 10%	.278 ,,	Do. do. 7 Lead, 16 Tin	.300 ,,

The figures given above are intended to represent average values, and if very near results are required the weight per cubic inch of the material in question should be obtained specially.

The Canadian Engineer

ESTABLISHED 1893.

ISSUED WEEKLY in the interests of the CIVIL, MECHANICAL, STRUCTURAL, ELECTRICAL, RAILROAD, MARINE AND MINING ENGINEER, THE SURVEYOR, THE MANUFACTURER, AND THE CONTRACTOR.

JAMES J. SALMOND, Managing Director

T. H. HOGG, B. A. Sc. Managing Editor — A. E. JENNINGS, Advertising Manager — P. G. CHERRY Circulation Manager

EXPERT TESTIMONY.

Very often the engineer is called upon to give expert testimony in cases before the courts, and oftentimes he is asked to prepare reports on the values of properties and damages to properties by public undertakings or improvements. In compiling these reports the subject must be looked at from every viewpoint, and the engineer must take the utmost care to maintain a fair and judicial attitude towards the claims of both parties. A prominent consulting engineer, in a recent address, states that it is quite easy to set up a theory of damages, and, assuming such a theory to be correct, to make figures which are favorable to the interests for which the expert is working, and this he considers proper, provided the engineer believes the theory to be correct and to meet the conditions fairly.

Recent expert medical testimony given in some of the recent criminal cases in the United States makes the public feel rather critical towards expert testimony in general. The engineer, in dealing with cases which require a judicial atitude, has a perfect right to work in the legitimate interests of his client, but he should also keep in mind the right of the opposing party. It is only by so doing that the engineering profession can be kept from falling into disrepute in connection with court cases.

CHEMICAL ANALYSIS OF CEMENT.

Much has been said recently with regard to the value of chemical analysis for the testing of Portland cement. Many chemists claim that the chemical analysis of a cement will indicate its quality better than a standard physical test. An engineer stated in the hearing of the writer a few days ago that in his opinion the chemical analysis method had not received the recognition for testing purposes that it deserved, and he inferred that the reason for this was the natural conservatism of the engineer with regard to a new idea. The United States Bureau of Standards has just issued Bulletin No. 33, covering the United States Government specifications for Portland cement, including specifications, standard method of testing, methods of chemical analysis, investigation of results and auxiliary specifications. The opinions there expressed leave little doubt as to the opinion of the Bureau of Standards concerning the chemical analysis method for determining the quality of cement. A normal Portland cement which meets the standard specifications for soundness, setting time, and tensile strength has an approximate composition within the following limits:—

	Per cent.
Silica	19.0 to 25.0
Alumina	5.0 to 9.0
Iron oxide	2.0 to 4.0
Lime	60.0 to 64.0
Magnesia	1.0 to 4.0
Sulphur trioxide	1.0 to 1.75
Loss on ignition	0.5 to 3.00
Insoluble residue	0.1 to 1.00

It is also true that a number of cements have been made both here and abroad which have passed all standard physical tests in which these limits have been exceeded in one or more particulars, and it is equally true that a sound and satisfactory cement does not necessarily result from the above composition. It is probable that further investigation will give a clearer under-

standing of the constitution of Portland cement, but at present chemical analysis furnishes but little indication of the quality of the material.

Defective cement usually results from imperfect manufacture, not from faulty composition. Cement made from very finely ground material, thoroughly mixed and properly burned, may be perfectly sound when containing more than the usual quantity of lime, while a cement low in lime may be entirely unsound, due to careless manufacture. The analysis of a cement will show the uniformity in composition of the product from individual mills, but will furnish little or no indication of the quality of the material. Occasional analyses should, however, be made for record and to determine the quantity of sulphuric anhydride and magnesia present.

The ground clinker as it comes from the mill is usually quick setting, which requires correction. This is usually accomplished by the addition of a small quantity of more or less hydrated calcium sulphate, either gypsum or plaster of paris. Experience and practice have shown that an addition of 3 per cent. or less is sufficient for the purpose. Three per cent. of calcium sulphate ($CaSO_4$) contains about 1.75 per cent. sulphuric anhydride (SO_3), and, as this has been considered the maximum quantity necessary to control the time of set, the specification limits the SO_3 content to 1.75 per cent.

The specification prohibits the addition of any material subsequent to calcination except the 3 per cent. of calcium sulphate permitted to regulate time of set. Other additions may be difficult or impossible to detect, even by a careful mill inspection, during the process of manufacture, but as the normal adulterant would be ground raw material, an excess of 'insoluble residue' would reveal the addition of silicious material, and an excess in "loss of ignition" would point to the addition of calcareous material when either is added in sufficient quantity to make the adulteration profitable.

The effect of relatively small quantities of magnesia (MgO) in normal Portland cement, while still under investigation can be considered harmless. Earlier investigators believed that as magnesia had a slower rate of hydration than lime, the hydration of any free magnesia (MgO) present would occur after the cement had set and cause disintegration. The effect of magnesia was considered especially injurious when the cement was exposed to the action of sea water. More recent investigation has shown that cement can be made which is perfectly sound under all conditions when containing 5 per cent. of magnesia, and it has also been found that the lime in Portland cement exposed to sea water is replaced by magnesia. The maximum limit for magnesia has been set at 4 per cent., as it has been established that the quantity is not injurious, and it is high enough to permit the use of the large quantities of raw material available in most sections of the country.

For some time, therefore, it will be better for the engineering profession to depend on the standard physical tests, at least until chemical analysis can furnish sure indication of the quality of the material.

EDITORIAL COMMENT.

Plumbers and gasfitters have arisen to the dignity of Sanitary Engineers. The advance guard who prepare the ground for a visiting circus class themselves as Circus Engineers. The profession is ever broadening.

A prominent contractor states that in one case the saving of concrete by reducing the size of columns on successive floors was $2.30 per column; on the other hand the increase in form cost was $5.70 per column, entailing a net loss of $3.40 per column. This is a very good example of why it is cheaper to use the same size column on successive floors than to reduce the dimensions. To avoid frequent changes in column sizes column reinforcement may be varied in successive stories.

* * * *

In this issue will be found the full report of the inquest into the collapse of the south wall of the Neilson building. We have endeavored to present the salient points of the evidence given by the several witnesses. Many matters of interest to the engineering profession were brought out, as may be seen by a perusal of the article. The evidence as given by Professor C. H. C. Wright was particularly clear, and his statements give a logical presentation of the reasons for the failure, with suggestions for changes in the city by-law, which the City Architect and the city will do well to heed.

EFFICIENT WATERWORKS.

The operation of the municipal waterworks of Berlin, Ont., under commission rule, has proved thoroughly successful. The plant was first installed in 1888, by Messrs. Moffett, Hodgkins and Clarke, of Syracuse, N.Y. They secured their supply from a pond, and had a ten-year franchise.

When it expired the ratepayers decided to take over the plant, at a valuation of $102,000. Then there were only 13 miles of mains, 104 hydrants and 732 consumers.

Under civic ownership, the system has grown to that stage where there are now 34 miles of mains, 218 public and 16 private hydrants, and 2,872 consumers, of which 2,229 are on meters.

The water supply has been greatly increased. Artesian wells have been sunk and the water is being pumped by the air-lift system.

But what affects the consumers most of all is the reduction in the rates and a purer supply of the drinkable.

Under private ownership, the rates for an ordinary house with full plumbing and lawn service, was $19 a year. Now, under municipal ownership, it is $4.59 for the same service, per year.

The minimum charge is now $1.12½ per quarter, for 6,250 gallons or less, and the rates for larger consumers range from 17 to 6 cents per thousand gallons, according to the quantity used.

In addition to the reduction of the rates to the private consumers, the charge for street hydrants, for protection from fire, have been reduced from $50 to $25, and there is now no charge for meter rentals.

The profits from the system, which have been used in extending the service, and the original debenture debt has been reduced to $85,465. And after writing off $32,000 for depreciation, the department shows a balance of assets over liabilities of $141,642.

The commissioners have the confidence of the citizens as there have been few objections—in the way of candidates to oppose members—raised.

The growing needs of the new city have made it necessary to enlarge and improve the system and the confidence of the ratepayers was shown when they passed a by-law to grant $100,000 for this purpose. Some of the contracts have been already awarded and it is expected that the work will be completed this year.

THE DESIGN OF INDUCTION MOTOR SHAFTS TO RESIST DEFLECTION.

By Mr. Bradley T. McCormick.*

The designer of electrical machinery is constantly confronted with the problem of reconciling the requirements of good electrical characteristics with reliability of service. A certain proportion of mechanical dimensions will give a machine which shows up best from the standpoint of electrical performance curves, but the proportions may be so extreme from the mechanical standpoint as to make the machine utterly unreliable.

A striking example of conflicting mechanical and electrical requirements is the polyphase induction motor as applied to industrial purposes.

In order to keep the power factor as high as possible it is necessary to design induction motors with the air gap or clearance between the rotor and stator as small as is consistent with reliable operation. Every precaution must be taken to obtain an accurate bore of the inside surface of the stator and a perfectly true rotor, with shaft and bearings of sufficient stiffness to limit the deflection to a small percentage of the normal length of the air gap.

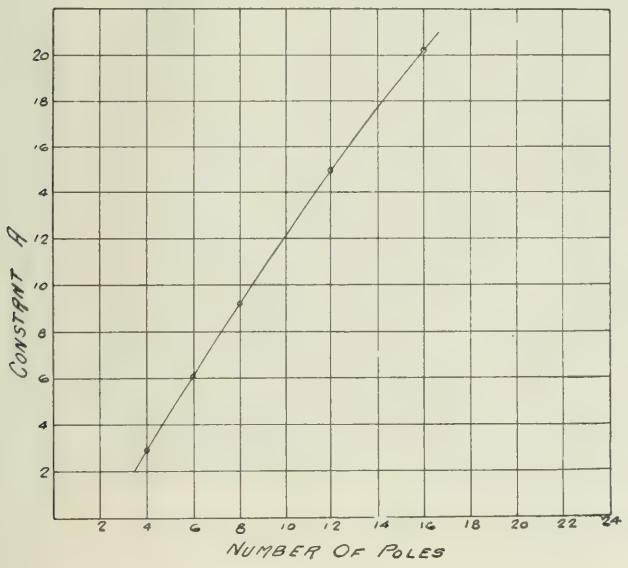

Fig 1

If the air gap is perfectly uniform, the radial magnetic attraction between the rotor and stator is the same at all points and is completely balanced; but if the clearance between the rotor and stator becomes reduced at any point, the decrease in reluctance of the air gap at this point and the increase in reluctance at a point diametrically opposite, set up an unbalanced magnetic attraction, tending to spring the rotor still more out of centre, and in some cases so far as to make it "rub" against the stator.

Fisher Hinnen, in his book entitled "Continuous Current Dynamos," gives the following formula for unbalanced magnetic pull:

$$z = \frac{\left(\frac{B}{1000}\right)^2 S}{72} \frac{x}{\Delta k} A \qquad (1)$$

while Behrend, in a paper before the American Institute of Electrical Engineers, November 23rd, 1900, gives for induction motor, a formula which in a slightly modified form is as follows:

$$z = \frac{\left(\frac{B}{1000}\right)^2}{\alpha} \frac{R c}{72} \frac{2 x}{\Delta} \% \qquad (2)$$

The meaning of the symbols is shown in the table at the end of the paper, all values being expressed in the inch system. The constant α is a fringing coefficient slightly greater than unity, and takes account of the higher reluctance of the air gap of a toothed armature as compared with a smooth core. The values of α given by Carter Electrical World and Engineer, (Vol. 38, Fig. 384), are recommended, but the following gives values of α which are close enough for all practical purposes. (See Fig. 2.)

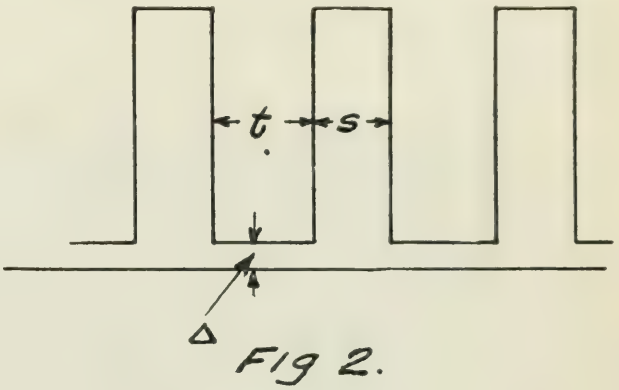

Fig 2.

$$\alpha = \frac{t + s}{t + \frac{5 \Delta s}{5 \Delta + s}} \qquad (3)$$

For direct current machines or alternators having salient poles, the flux density is fairly uniform over the pole face and may be taken as

$$B = \frac{\varphi}{\tau L \alpha} \% \qquad (4)$$

while in induction motors the flux density over a pole pitch approximates a sine distribution, so the square root of mean

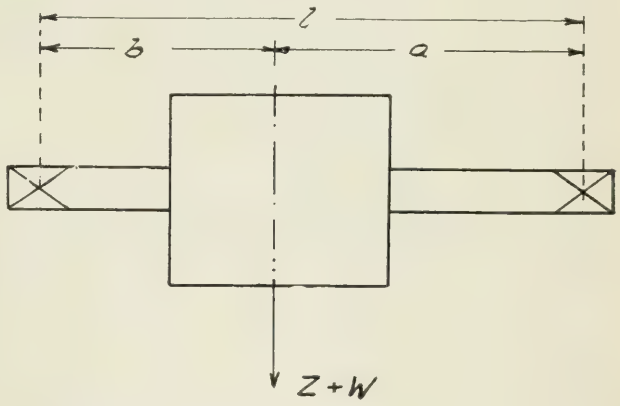

Fig 3

square value should be used for B, since it enters into the formula for unbalanced pull, in the second power. For induction motors use

$$B = \frac{\varphi}{\tau L} \frac{\pi}{2} \frac{I}{\sqrt{2}} \alpha = 1{\cdot}11 \frac{\varphi}{\tau L} \alpha \qquad (5)$$

* Electrical engineer for Allis-Chalmers-Bullock, Ltd., Montreal.

The following is used for air gap area, the factor % being unity in induction motors,

$$S = \frac{\tau L \%}{\alpha} \qquad (6)$$

Fisher Hinnen's formula (1) although evidently intended more for direct current machines, checks fairly well with Behrend's formula (2).

We shall first assume that, due to imperfect assembling or non-uniformity of the stator bore, there is an initial eccentricity equal to e. When the machine is excited this initial eccentricity gives rise to an unbalanced magnetic pull Z, which increases the eccentricity to an amount $x = (e + d)$ to such a value that the magnetic pull, plus the weight of the rotor, is just balanced by the tendency of the shaft to resist further flexure.

And the deflection due to weight alone is,

$$\delta = \frac{W a^2 b^2}{3 l E I} \qquad (10)$$

The total eccentricity is,

$$x = d + e \qquad (11)$$

The stress in the shaft can be calculated from the total pull W + Z, while the deflection of the shaft from its natural unstrained position is,

$$\text{Total deflection in shaft} = d + \delta \qquad (12)$$

As a method of procedure in applying the above formulas, the writer would suggest that, having decided upon the length of the air gap Δ, a shaft be chosen that appears to be large enough and then checked for stiffness on the assumption of a reasonable initial deflection. As a first approximation in determining the size of the shaft, it is considered good practice to adopt a shaft large enough to limit the deflection due to weight alone, to one-tenth the normal air gap. For checking purposes, however, the initial eccentricity should preferably be assumed somewhat greater than $\Delta/10$.

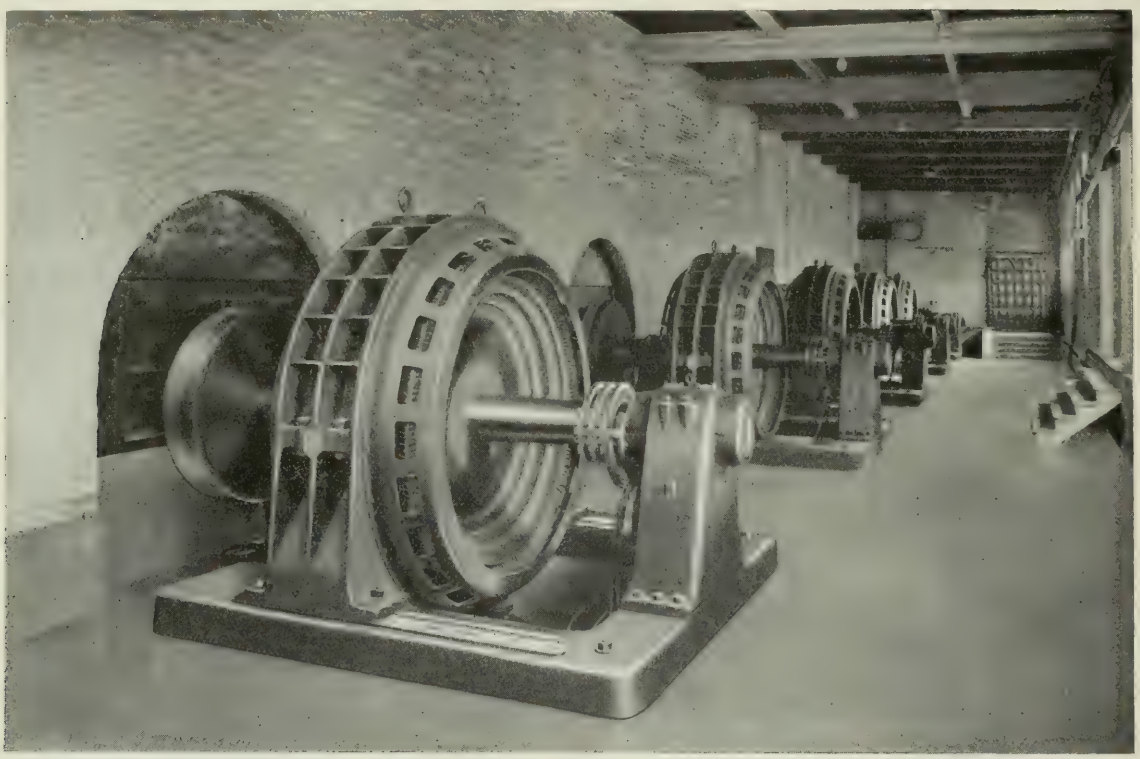

Fig. 4.—Five Induction Motors, Each 1,200 h.p., Driving Grinders, Union Bag and Paper Company, Three Rivers, Que.

Using Fisher Hinnen's formula (1)

$$z = \frac{\left(\frac{B}{1000}\right)^2 S}{72} \cdot \frac{x}{\Delta k} A = K (e+d) \qquad (7)$$

When K is the magnetic pull per inch of displacement of the rotor from a central position, which from formula (1) equals

$$k = \frac{\left(\frac{B}{1000}\right)^2 S A}{72 \Delta k} \qquad (8)$$

Leaving the weights out of consideration, but taking the deflection due only to the magnetic pull Z, we have. (See Fig. 3).

$$d = \frac{z a^2 b^2}{3 l E I} = \frac{K (e+d) a^2 b^2}{3 l}$$

Solving for d

$$d = \frac{e}{\frac{3 l E I}{K a^2 b^2} - 1} \qquad (9)$$

The motors were to be subjected to rather rough service as they were designed to drive grinders in a pulp mill, where the torque often suddenly rises to 50 or 100 per cent. above normal when the logs are fed too fast to the grinding stones. The wide space between bearing centres necessary to permit lateral movement of the yoke, and the small air gap necessary to obtain good power factor with open slots, requires that special consideration be given to the design

As a practical example we will apply the foregoing formulas to some 1,200-horse-power induction motors which the writer was recently called upon to design. The specifications called for motors constructed in such a way as to allow the yoke to slide along the base in a direction parallel to the shaft, far enough to completely uncover the rotor winding, in order that the coils might be readily accessible for repairs.

of the shaft, in order to secure stiffness against deflection due to the weight of the rotor and unbalanced magnetic attraction between the rotor and stator. This point will be readily appreciated by reference to the heavy shaft and long

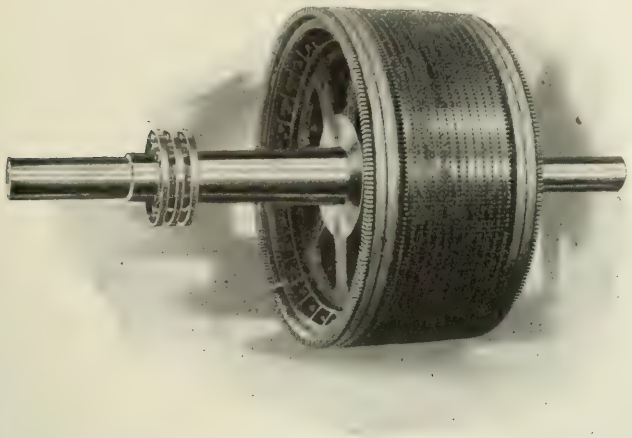

Fig. 5.—Rotor, Showing Long Space Between Bearing Centres.

space between bearings, as shown in Figs. 4 and 5. The following values apply to these motors:—

A = 17.5 for 14 poles (See Fig. 1).
L = 32.2 sq. in.
φ = 6.7 x 10^6.
Δ = .09".
k = 1.115 from calculated saturation curve.
Diam. of shaft 14" at hub.
I = 1880 = moment of inertia of shaft.
e = assume .02.
α = 1.37.
w = 15,000 lbs.
a = 72" (See Fig. 6).
b = 37" (See Fig. 6).

Calculated Values.

Form (5) $B = 1.11\frac{\varphi}{\tau L} = 1.11\frac{6.7\times10^6}{32.2}\times 1.37 = 31700$

Form. (6) $S = \tau L\,\%/\alpha = 32.2\times 1/1.37\times 235$ sq. in.

Form. (8) $K = \frac{\left(\frac{B}{1000}\right)^2 S\,A}{72\,\Delta\,k} = \frac{31.7^2\cdot 235\times 17.5}{72\times .09\times 1.115} = 560{,}000$ lbs.

Form. (9) $d = \frac{e}{\frac{3\,l\,EI}{K\,a^2\,b^2 - l}} = \frac{.02}{\frac{3\times 109\times 30\times 10^6\times 1880}{560000\times 72^2\times 37^2} - 1} = .0055$

Form. (11) $x = d + e = .0055 + .02 = .0255$

Form. (10) $\delta = \frac{W\,a^2\,b^2}{3\,l\,E\,I} = \frac{15000\times 72^2\times 37^2}{3\times 109\times 30\times 10^6\times 1880} = .00577$

Form. (12) total deflection of shaft $= d + \delta = .0055 + .00577 = .01127$

Form. (7) $z = \frac{\left(\frac{B}{1000}\right)^2 S}{72}\,\frac{x}{\Delta\,k}A = \frac{31.7^2\times 235}{72}\times\frac{.0255}{.09\times 1.115}\,17.5 = 14200$

Total Pull on shaft = W + z = 15000 + 14200 = 29200 lbs.

Symbols.

B = density per sq. in. in air gap, the increase due to fringing being included.

S = air gap area per pole corrected for fringing $= \frac{\tau L}{\alpha}$ for induction motors $= \frac{\tau l}{\alpha}$ for salient pole machines.

Δ = actual air gap (normal).
e = initial eccentricity with no excitation, due to imperfect centring.
d = additional deflection due to magnetic pull.
χ = total amount of eccentricity = d + e.
A = a constant depending upon the number of poles. (See Fig. 1).
For large number of poles, A = 1.25 × number of poles.
k = (gap + iron) A.T. ÷ gap A.T.
K = deflection per inch of eccentricity $= \left(\frac{B}{1000}\right)^2$ S.A./72 Δ k.
a and b = distance from armature centre to bearing centres, in inches.
l = distance between bearing centres, in inches.
E = modulus of elasticity of shaft.
I = moment of inertia of shaft about neutral axis = $1/64\pi D^4$.
W = weight of armature, in pounds.
δ = deflection of shaft due to weight alone.
ϕ = flux per pole.
τ = pole pitch.
α = Carter coefficient for fringing.
L = effective length of iron parallel to shaft. (Fisher Hinnen's formula).
R = radius of stator, inches.
c = effective length of iron parallel to shaft. (Behrend's formula).
% = pole arc ÷ pole pitch. This is necessary to make Behrend's formula applicable to alternators and D.C. machines.
D = diameter of shaft at hub.
t = width of tooth at air gap.
s = width of slot.

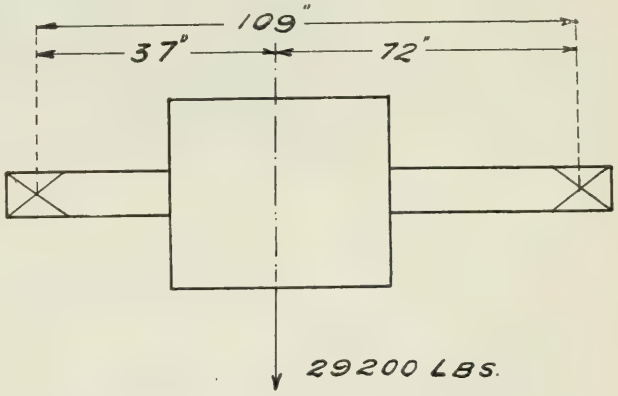

Fig. 6.

THE DRYDOCK AT QUEBEC.

Mr. F. G. Wilson, who has prepared a report on the proposed Quebec drydock, has placed his papers in the hands of the proper government officials. Mr. Wilson has gone over the ground and made a careful examination of all the plans, including the latest submitted by Mr. Cravin.

Besides examining the merits of the different plans and the different sites, he has taken information from a number of practical shipping men with regard to the ice conditions, etc., and has sounded them as to their opinions on the merits of the two sites. Naturally these opinions vary somewhat, but from what has been learned it is understood that the site will be on the south shore of the St. Lawrence. Mr. Wilson is from Great Britain and is considered an expert in matters pertaining to drydocks.

THE HYDRO-ELECTRIC PLANT OF THE SIMCOE RAILWAY AND POWER COMPANY.

An interesting hydro-electric installation which has been completed and in service for some months is the plant of the Simcoe Railway and Power Company, at Big Chute, on the Severn River. It serves with electric power the towns of Midland, Penetang, Victoria, Ontario Harbour, Port McNicholl, Coldwater, Barrie and Orillia, in the counties of Simcoe and Muskoka. The installation is the largest hydraulic development in the Georgian Bay District and has an ultimate capacity of 7,000 h.p.

Development was started in the fall of 1909, and in May, 1911, 4,200 horse-power was developed and commercially available in Midland. The power market will include the municipal and industrial operations in the towns in the vicinity and in addition the flour mills and immense grain elevators now constructed after the determination of the Canadian Pacific and Grand Trunk Railways to make the district the terminus of the lake carrying portion of the grain route from the West. The natural market possibilities are large and will doubtless soon necessitate the further extension of the Big Chute plant and the development of the Little Chute and the falls at Port Severn, in the near future: the latter sites are now held by the power company.

View of Generating Station.

The general location of the Severn River waterway system is such as to drain all that portion of Central Ontario in the vicinity of Lake Simcoe and comprises a total watershed area, above the Big Chute, of about 2,250 square miles. This area is constituted as follows:

Land area, including small streams, 1,800 sq. miles.

Water area: Lake Simcoe, 300 sq. miles; Lake Couchiching, 15 sq. miles; Sparrow Lake, 5 sq. miles; other various lakes and large rivers, 130 sq. miles.

The general nature of the country drained has two characteristics. The southerly portion of the area comprises rolling and flat country and the northerly portion, rough, rocky and hilly regions. At one time the area was wooded but recent lumbering operations have deforested the northerly portion very rapidly, only a portion at the extreme north-easterly end and isolated districts in the north-west still remaining. Probably seventy per cent. of the area may be generally termed settled, the southerly portion being fairly dense and the north, sparsely. Settlement, however, is proceeding in the north and the streams are consequently being improved and lands drained. Owing to the large proportion of lake area in the watershed the discharge of the Severn River is comparatively steady throughout most of the year, as the lakes act as regulating reservoirs.

Based on continual measurements during the last twelve years, the flow of the Severn above the Big Chute locality for practically the whole year will, it is estimated, not fall below 950 cubic feet per second excepting from the middle of January to the middle of March. Water control of the head lakes will effectually conserve the water supply and, deforestation having reached its limit, reforestation will gradually retard the run-off to benefit the continual flow.

Temperatures in this district run very low in the winter, short periods at 30 degrees below zero not being uncommon. The result of this is the formation of very thick sheet ice on the quiet waters of the river and of a certain amount of frazil ice in the falls and rapids as the broken water is exposed to the cold air. The Big Chute site is fortunately situated in this respect, as for a distance of ten miles above the chute the few very slight "swifts" are flooded out. At Ragged Rapids, ten miles above the Big Chute, the town of Orillia has developed power so that those rapids have been flooded and during the winter practically all the water is passed through their hydraulic system without coming in contact with the air. It is evident that there is practically no opportunity for the formation of anchor or frazil ice which would affect the Big Chute plant.

The Severn River in the locality of the development has three points of discharge over the bridge forming the falls. These are Lost Channel, Six Mile Channel, and Big Chute; the former are distant 2½ and 1 mile upstream from the Big Chute. The river at Big Chute makes a straight rapid series of falls through a narrow gorge for about 300 yards after which the stream divides, part going straight to the lower pool, the main part, however, passing to one side into a middle pool, thence out into the lower pool over a small cascade 2 feet in height. The total natural fall under normal conditions is 50 feet.

The general hydraulic portion of the development included the construction of dams, intake, canal, forebay, gates, spillway, penstocks, power station, hydraulic machinery and tail discharge, the whole providing for a development of 58 feet head.

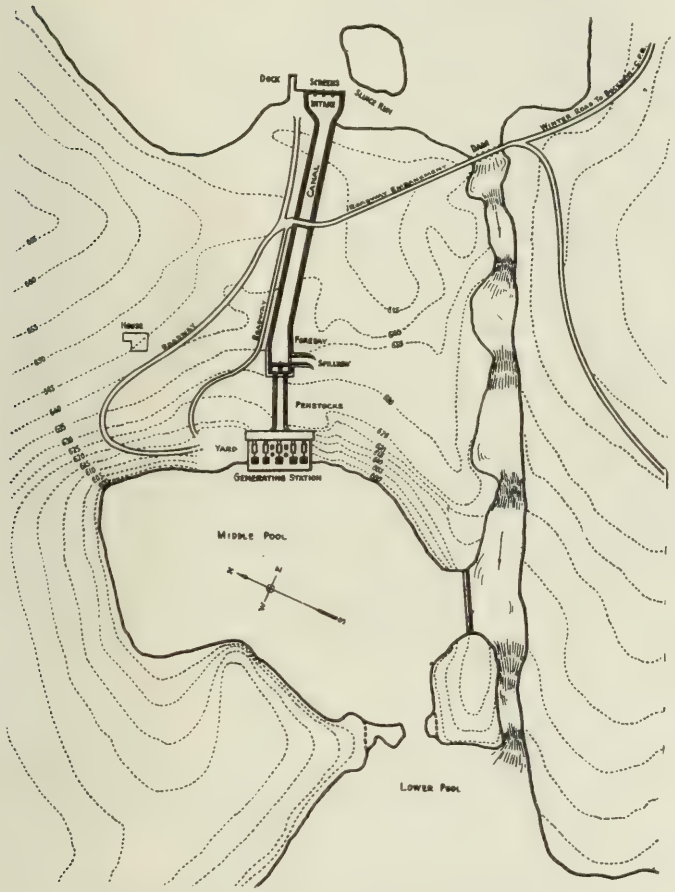
The Big Chute dam consists of massive piers and concrete sills with stop logs and spill crests. The piers are bridged over and form the roadway bridge for the winter road and for the road from a boat landing some two miles below to which the river is navigable from Port Severn on the Georgian Bay; the winter road is direct to Buckskin Station on the Toronto-Sudbury line of the Canadian Pacific Railway.

Lost Channel dam is located in a narrow gorge and consists of stop logs seated in shore piers. The Six Mile Channel dam is of similar construction to the Big Chute dam.

The water is carried through a canal from the upper level to the forebay at the brow of the rocky ridge above the middle pool and from thence to the power house through steel penstocks and is discharged from the turbines into the middle pool underneath the power house and thence into the lower pool below the foot of the chute. The chute is dammed where dividing at the "Twin Falls" to compel the overflow water to go directly to the lower pool; the rocky

ridge between the middle and lower pools has been removed and the difference in level gained for the lower head.

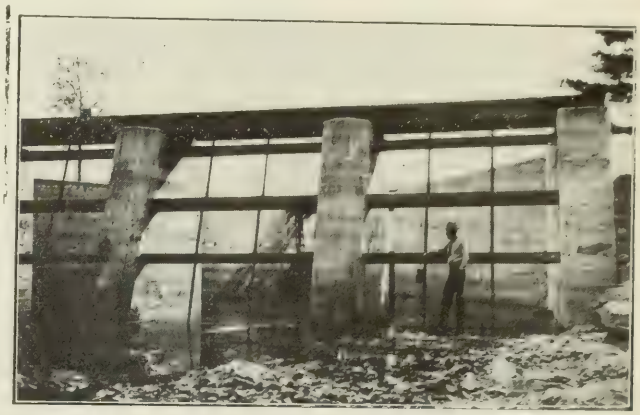
The canal entrance widens out to form an intake which is protected with four sets of racks supported by the concrete piers. The photograph of the intake shows the piers and framing for racks and further shows the canal in the background. Racks are of iron with wooden tops extending out of the water so that the frost from the air cannot be conducted to the iron portion in winter, thus preventing the freezing up of the openings between rack bars. The concrete is built up on the solid bed rock and continues along as lining for the canal to the forebay. Stoop log seats are arranged at the entrance from intake to canal so that the head-water can be shut off entirely from the canal. A sluice run has been excavated alongside the intake in the river bed to take care of the ice and debris.



Plan Showing General Layout of Headworks and Generating Station.

The canal is about 500 feet long and terminates in a forebay from which two steel penstocks, nine feet in diameter, lead down to the power house. The forebay is protected by a housing which will be heated in extreme weather; a curtain of 8 x 10 timber extends from the housing sills downwards into the water and both encloses the air space in the forebay and acts as an ice and trash boom in front of the racks. A spillway with adjustable stop-logs, forward of the curtain, regulates the water level and discharges debris; a small sluiceway is placed in front of the racks, in the housed portion, and carries out any debris caught by the racks. Both spillway and sluice discharge into a natural gully in the rock and flow down to the lower pool. The racks are of iron bars arranged for easy handling and raking. The penstock entrance has a large bell-shapel mouth about 13 feet in diameter; stop-logs with handling winches act as penstock gates.

Up to this point the development is for the ultimate output, but at present but one of the penstocks is installed. The total machinery provided for will be 6,800 h.p. of hydraulic turbines; at present 4,200 of this is installed, in three main units and two exciters, leaving two main units to be installed later. The third power turbine will be fed ultimately from both penstocks with a Y connection and the exciter will be also arranged to connect to either source.



Intake to Power Canal, Unwatered—Severn River.

The penstock is carried on several concrete piers for about 150 feet down the slope and turns along the rear of the power house, terminating in a surge tank extending to an elevation four feet above that maintained in the forebay. Nos. 1 and 2 turbines are connected with the penstock by diverging feeders and No. 3, the centre unit, is connected by the present portion of the Y connection. No relief valves are installed on penstock or turbines, the surge tank being ample to take care of all pressure changes.

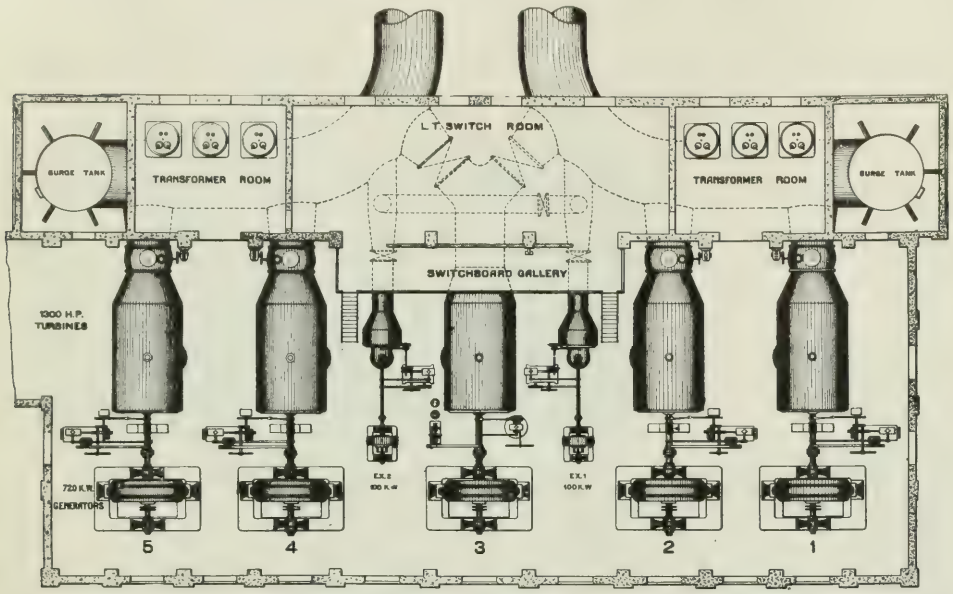
The power house is built on a ledge of rock extending into the lower pool and sufficient excavation was made into the cliff behind to allow the foundations to lie completely on the ledge. The piers and foundations are of massive concrete extending about 23 feet from bed rock to floor level. All piers and walls are tied into one another above the water line, and again at the floor line, by reinforced struts and

Diverting Dam at Big Chute, Severn River.

beams making an essentially homogeneous structure. The tail race extends longitudinally under the floor line and has large openings to the tail water between the generator piers and through arched openings in the outer wall.

The walls are of concrete slabs between heavy pilasters, the pilasters carrying the crane rail and roof trusses. The

rear portion of the station has the floor eleven feet higher than the generating room floor leaving space for the penstock and feeders underneath; this floor contains the low tension switchboard and its equipment and the transformers while a second floor above the switching room contains the high tension switching and line equipment. The rear portion of the building has a heavy concrete roof carried on



Section Through Generating Station, Showing Arrangement of Turbines, Generators and Transforming Equipment.

reinforced beams while the roof of the generating room is 1¼-inch matched pine carried on heavy wooden purlins which are hung by wrought iron hangers from the steel roof trusses. Both roofs are covered with several layers of asbestos felt laid in asphalt cement; the Johns-Manville Company were the contractors for this portion of the work. The general works and the power station were constructed by Messrs. Pratt & MacDougall, of Midland.

The turbines were built by the William Hamilton Company, of Peterborough, Ontario, are are of the "Samson" type. The power turbines are designed for 1,300 horsepower capacity under 56 feet head and a speed of 300 revolutions per minute. The double runners, of the Francis type, are of bronze, 35 inches in diameter, and the water discharges into a single steel draft tube inclined towards the front of the power house. The turbine case is carried on a series of heavy "I" beams spanning the tail race.

A 66-inch vertical gate valve is set in the horizontal feed pipe between each turbine and the penstock; the valve is erect in Nos. 1 and 2 units while in No. 3 the stem is downwards and is protected by a concrete housing. All 66-inch valves are being arranged for alternating current motor operation while the auxiliary hand mechanism will allow for complete opening or closing in about two hours by one man. The valves have strongly ribbed cast iron bodies with bronze mountings on all bearing and rubbing faces. Each valve is tested to a working pressure of 50 lbs. per square inch and operation under 75 feet head. A six-inch by-pass with valve is provided with each.

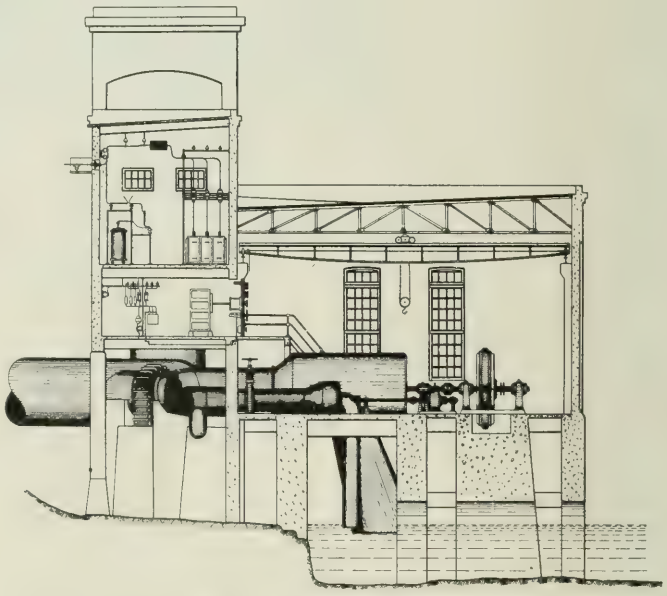
The exciter turbines are of the single runner type, 17 inches diameter, and are capable of producing 200 horsepower under 56 feet head at 580 revolutions per minute. The valves on exciter feeders are 30 inches in diameter.

The hydraulic turbine governors are all of Lombard oil pressure design, types N and Q 7½ being installed for power turbines and type P for exciters. The governors in combination with the surge tank on the penstock, and the heavy fly-wheel effect of the generators, have given excellent results on test while with the surge tank acting and full load thrown off the turbines the pressure rise in the turbine cases is hardly appreciable.

The power generators are of Canadian Westinghouse Company's manufacture, as is practically the whole of the electrical equipment. These generators are of 900 kv.a capacity, 2,200 volts, 60 cycles, three phase at 300 revolutions per minute. The armatures are wound in three slots per pole per phase, the slots being open; the field is revolving and the rotor will withstand the stresses of a runaway speed 75 per cent. in excess of normal.

The exciters are of 100 kilowatts capacity at 125 volts and are controlled by means of a Tirrill regulator to automatically produce a varying strength of field on the power generators to maintain a constant voltage at the end of the 25-mile transmission line. The two exciters are direct connected to their turbines. The turbines are arranged to take water from either penstock, when the second penstock is installed or for each to be fed from a separate penstock, thus providing for continuity of exciter current.

The current from all generators on the main floor is carried through cables, laid in fibre conduits, to the switchboard on the gallery and from thence to the transformers and ultimately through the high tension switching room to the line.



Plan of Generating Station.

The transformers are three single phase units agregating 1,800 kilowatts capacity. These are connected in delta so that in case of accident to one unit the two other may be used for continuing the service. The voltage ratio is 2,200 to 25,000, the latter being the transmission voltage. Water for transforming cooling purposes is supplied through the station water piping from the stand pipe; a cleaning strainer is attached to the source.

The electrical circuits are arranged so that each generator may be switched on either of two sets of 2,200 volt bus-bars. Each of these bus-bars feeds into one 1,800 kw. transformer bank through a circuit breaker and the two transformer sets may then be connected in parallel by a tie oil switch. Each transformer set on the high tension side feeds to a 25,000 volt bus-bar to which the transmission line is connected through the line circuit breaker. When the second transmission line is constructed the high tension bus may be divided so that each of the two transformer sets may feed their corresponding lines independently.

The switchboard consists of twelve black marine finish marble panels which are arranged in three groups, spaced by the concrete columns which extend from the switchboard gallery floor, so that the five generator panels and the bus tie switch panel are between the columns while on the left is the direct current board of three panels, including the Tirrill regulator and on the right are the two transformer panels (one blank at present) and the line panel. The gallery extends six feet into the generator room while behind is ample room for the 2,200 volt bus and switch structure and the generator rheostats. The rheostats are carried on concrete pedestals to allow for ventilation, and are operated by shafts in a straight line between rheostat handle on the switchboard and the face plate on the rheostats.

In the transformer room disconnecting switches are arranged inside the low and high tension delta connections so that any single phase transformer can be temporarily cut out. The leads on the high tension side are carried through a wall opening into the line room where the three 25,000 volt oil switches, the electrolytic lighting arresters and the choke coils are located as shown in one of the accompanying photographs.

The transmission line outlets are at the rear of the power house and consist of porcelain outlet insulators in a 14-inch opening in the concrete wall. The outlet is protected outside by a hood of a one-half section of a 42-inch corrugated iron culvert carried on steel angle brackets inserted in the wall; this has proven a very cheap and effective outlet covering.

The transmission line is approximately 25 miles long, the route being south-west to Waubaushene on Georgian Bay, and thence to Midland, generally following the roadways along the Georgian Bay shore line. Half of the distance, from the Big Chute to Waubaushene, is over the company's right-of-way, which has been cleared and laid out for two parallel transmission lines.

The poles are generally 35 feet in length graded to conform to the profile of the route. The conductors are No. 00 B & S aluminum cable supplied by the Northern Aluminum Company and are carried on 35,000 volt porcelain insulators spaced in an equilateral triangle, forty-two inches apart with the apex at the top of the pole. A photograph shown herewith indicates a typical portion of the line. Special pole arrangements were made for railway and telephone crossings.

A telephone line extends from Big Chute to Midland, carried on the pole line. Heavily insulated transformers are placed at each terminal with the local services on the secondaries so that no accidental high voltage on the telephone line can be dangerous to the telephone operators.

At Waubaushene, the Matchedash Bay arm of Georgian Bay is about 2,000 feet across and two spans are made, 1,153 and 858 feet respectively. The longer span also crosses the ship channel which is close to the west shore and the Government requires 150 feet clear at this point between wires and water, necessitating a 175-foot tower; the centre and east shore towers are 88 feet high, giving a forty foot clearance on the 858 foot span. The long span is made with copper cable of 7 No. 9 B & S strands, while the 858-foot span is made with 300,000 c.m. aluminum cable, the copper and aluminum being spliced together at the centre tower with a special aluminum clamping device, while the other ends are clamped to a 2 unit suspension insulator. The cross arm decks of the shore towers are fitted with iron sheaves and turnbuckles, so that tension may be put on the steel cable supporting the insulators to allow for adjustment of the sag, should occasion demand. The connecting cables are attached to the span cables at the suspension insulators and are carried down the sides of the towers on insulators to within 50 feet of the ground, and from thence to the pole line. The towers are arranged with gusset plates at the top to accommodate an additional deck so that a second line may be eventually carried above the first.

At Midland the company has acquired a plot on the outskirts for the sub-station and construction yard. The sub-station is of brick arranged for extension as the market may demand. The present equipment has transformers, line apparatus and a switchboard similar to those of the generating station. Distribution is at 2,300 volts to Midland and the surrounding district. The Hydro-Electric Commission undertakes the distribution in Midland and Penetanguishene.

The Simcoe Railway & Power Company is formed of well known business men connected with the various large concerns in Midland, the officers being: W. J. Lovering, Toronto, president; W. Finlayson, Midland, secretary, and D. L. White, Midland, treasurer.

The engineering of the development was carried on by Messrs. C. H. and P. H. Mitchell from its inception. The resident engineers were Murray C. Hendry, B.A.Sc., during construction, and O. L. Flanagan, B.A.Sc., during installation.

EDMONTON NOTES.

The Allsip Brick and Supply Company have about completed installation of their plant at Edmonton at a cost of $100,000, and will in a few days begin turning out brick at the rate of 85,000 per day. The Hardstone Brick Company are busy installing extensive machinery. The Edmonton Brewing and Malting Company have let a contract for a fireproof building which will be equipped with the most thoroughly modern plant at a total cost of approximately $450,000. Work is progressing on a handsome $100,000 office for the Royal Bank. Rapid progress is being made on the $350,000 addition to the Tegler Block and the $250,000 office building for the Canadian Pacific Railway. Contracts aggregating over $250,000 have been let for an office block to be erected by the city.

Steel work is progressing rapidly on the big Canadian Pacific Railway bridge and the work of grading for their line into the heart of the city is proceeding. The Athabasca Landing branch of the Canadian Northern Railway has reached that point, and construction trains are now running. The Brazeau branch of the Canadian Northern Railway has been opened for traffic to Rocky Mountain House. The Grand Trunk Pacific branch to Calgary is being pushed.

The Hudson's Bay Company's sale of a portion of their reserve, which opened on 14th May and closed to-day, was an extraordinary indication of confidence in Edmonton's continued development. Though the lots offered were in a district absolutely undeveloped, the entire 1406 lots offered were sold at figures aggregating $4,343,400. Lots averaged 50 x 150 feet.

PUBLIC ROADS, NEW JERSEY, U.S.A.

By E. A. James, B.A.Sc.*

Since the passage of the State Aid Law in New Jersey the Commissioners of Public Roads in that State have spent $3,230,336, and completed 1,778.896 miles, making an average cost of $2,045 per mile.

The class of road varies with the location, but out of 13,550,000 square yards built 6,082 square yards was macadam, 2,394,000 square yards Telford, 4,119,320 square yards gravel, 449,100 asphalt macadam and 244,851 square yards of amiesite, the balance being made up of small quantities of shell, bogore, etc., etc.

Yardville-Allentown Macadam Road, Before.

Many of their costs are very interesting, but as an example we will take the Yardville and Allentown Road, 3.04 miles long. This was built as a macadam highway and treated with heavy asphaltum oil, and was built under the following specifications:—

All stone must be as nearly cubical as possible, broken with the most approved modern stone crushing machinery. It must be of trap or approved native rock, free from all screenings, clay, soil or other objectionable substances, of uniform size and of the same kind and quality as sample. It must show a fresh, crystalline surface.

Macadam foundation or two and one-half-inch stone shall be broken stone, which must pass through a three-inch ring and catch on a two-inch ring.

Macadam second course or one and one-half-inch stone shall be broken stone, which must pass through a two-inch ring and catch on a one-inch ring.

Macadam surface or three-quarter-inch stone shall be broken stone, containing not over 5 per cent. of material retained on one-inch circular openings or 8 per cent. which will pass one-half-inch circular openings.

Dustless screenings shall be broken stone taining not over 5 per cent. of material retained on ⅝-inch circular openings or 8 per cent. which will pass one-quarter-inch circular openings.

Dust shall be broken stone and include all material which will pass one-quarter-inch circular openings. but must be free from soil, loam or clay.

Length of stone-bed, 17,992.5 feet.
Width of stone-bed, 14 feet.
Depth of stone-bed, not less than 6 inches deep.
Average width of shoulders, 7 feet.
Average total width of improved roadway, 28 feet.

Excavations, 8,150 cubic yards., at 50 cents; total.	$ 4,075.00
Macadam, 28,736 square yards, at 94 cents; total.	27,011.84
Macadam driveways, 564 square yards, at 50 cents; total	282.00
Underdrains, extra, approved by State, 1,500 lineal feet, at 20 cents; total	300.00
Extra, reconstructing class B macadam, 42⅔ square yards, at 94 cents; total	40.11
Extra, reconstructing driveway, macadam, 16 1/9 square yards, at 50 cents; total	8.06
Extra, reconstructing driveway, macadam, 33⅓ square yards, at 50 cents; total	16.83
Total cost	$31,733.84

Maximum grade before .....3.00 per cent.
Maximum grade after .....2.35 per cent.

As was pointed out in the opening paragraph, gravel constituted an important material of construction. As an example of a gravel road the Monmouth Boulevard will serve to illustrate. This road is 2.6 miles long, and was built under the following specifications:—

Road gravel A is to be composed of pebbles, chert, sand, clay and oxide or hydrate of iron, in such quantities that the gravel will pack under pressure into a hard, dense pavement. It will be judged solely by comparison with the samples furnished.

Road gravel B is gravel not deemed suitable for surface work, but may, on approval of sample by the engineer and State Commission of Public Roads, be used for foundations of gravel roads.

Yardville-Allentown Road, After. Water-Bound Macadam; Surface Oil.

The gravel of which the road was built was spread to a width of from sixteen to eighteen feet, and the entire roadway was graded to a width of thirty feet.

The value of this improvement is well attested by the almost constant, continuous traffic passing over it.

* Chief Engineer for the York Highway Commission, Toronto, Ont.

Width of gravel-bed, 16 and 18 feet.
Width of gravel shoulders, 6 feet.
Length of gravel-bed, 13,809 feet.
Depth of gravel-bed, 8 inches.
Depth or gravel shoulders, 4 inches.

Gravel (A), 6,081 cubic yards, at $2.25; total..	$13,682.25
Gravel shoulders (B), 1,729 cubic yards, at $2.25; total	3,890.25
Earth excavation (A), 10,944 cubic yards, at 25 cents; total	2,736.00
Earth excavation (B), 1,164 cubic yards, at 25 cents; total	291.00
Drain, 4,000 lineal feet, at 12 cents; total	480.00
12-inch pipe relaid, 425 lineal feet, at 8 cents; total	34.00
Total	$21,113.50
Less difference between items and lump sum	113.50
Total	$21,000.00
Supervisor's salary	606.00
Engineering expenses	630.00
Extras, 371 cubic yards excavation, at 25 cents; total	92.75
Total cost of road	$22,328.75
Maximum grade before	3.25 per cent.
Maximum grade after	2.75 per cent.

Although there are less than a quarter of a million square yards of asphaltic concrete used, yet, because of its long life and its dustless surface, asphalt concrete will be more largely used in the future. In Union county 1.5 miles was laid.

The pavement is sixteen feet wide while the road is graded to a width of from thirty-three to thirty-six feet.

Width of stone-bed, 16 feet.
Length of stone-bed, 8,362 feet.
Depth of stone-bed, 7 inches.

Cedar Avenue and Monmouth Boulevard, Gravel, Before.

Amiesite, 15,715.1 square yards, at $1.29; total..	$20,272.48
Macadam at driveways, 680.3 square yards, at 55 cents; total	374.17
Earth excavation, 16,460.2 cubic yards, at 35 cents; total	5,761.07
Cobble stone gutters, 252.8 square yards, at 60 cents; total	151.68
Total	$26,559.40
Supervisor's salary	321.00
Extras, paid by county, relaying pipe and moving stone pile	85.12
Total cost of road	$26,965.52
Maximum grade before	8½ per cent.
Maximum grade after	5.24 per cent

Cedar Avenue and Monmouth Boulevard, Gravel, After.

This pavement was laid under the following specifications:—

All pavements which are composed of a mineral aggregate held together with a bituminous cement, and are mixed without heating the mineral aggregate, and laid while cold, must conform to the following additional requirements:—

Pavements of this type must be prepared from bituminous cements.....and may be laid either in one or two courses. When laid in two courses the bottom course must not be less than 1½ inches thick after ultimate compression and contain not over 30 per cent. of material which will pass openings one-half inch in diameter. This course of stone must be uniformly coated with sufficient asphalt to bind it firmly together. It must be laid and rolled to the proper grade and curvature before the top course is applied.

The top course must not contain any material which will not pass openings three-quarter-inch in diameter. It must contain not less than five per cent., nor more than nine per cent., by weight, of bitumen soluble in cold carbon bisulphide; the exact amount to be determined between these limits by the State Department of Public Roads.

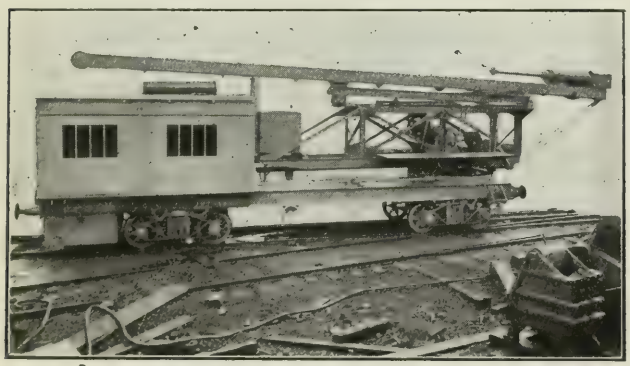
After the bottom course has been spread, it must be protected from all travel and kept free from dust or dirt until the top course has been spread and rolled into place or sealed in the manner specified hereinbelow. If the bottom course gets wet after being spread, it must be allowed to dry out before being rolled or covered with the top course. When dry it must always be covered with the top course at once, after being properly rolled, and in no case shall the bottom course be spread over three hundred feet in advance of the top course, nor shall over fifty feet be left uncovered during the night.

When pavements of this type are laid in one course, they will be sealed by painting the surface with a squegee coat of hot bituminous cement, when required by the State Department of Public Roads. This cement must be the same used in preparing the pavement, and must be applied at a temperature between 135° C. to 180° C. by a distributor which has been approved by the State Department of Public Roads. Immediately after this coat of bitumen has been spread, and while the same is yet hot, sand, fine clean gravel or screenings, or a mixture thereof, shall be spread over its surface and rolled at once.

These three classes of pavements give a good idea of the standards adopted by the New Jersey Commissioner of Public Roads, also of their costs.

A SELF-PROPELLED STEAM PILE-DRIVER.

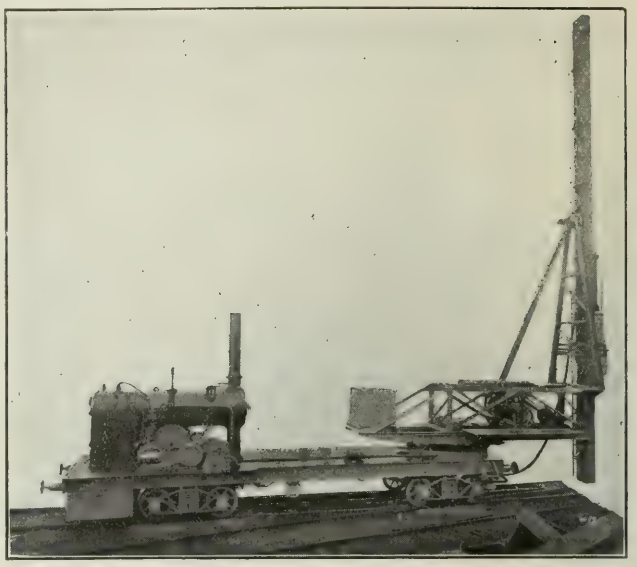
The photographs illustrate a locomotive steam pile-driving plant which has lately been completed by Messrs. Whitaker Brothers, Limited, of Horsforth, near Leeds, England, for service on the 5 ft. 6 in. gauge lines of the Central Argentine Railway. The equipment is claimed to be one of the largest and most complete machines of its kind ever constructed. It consists principally of a swivelling pile-driving frame with engine, boiler, winch, and all gearing and accessories mounted on a carriage running on two four-wheeled diamond-framed bogies. The machine is designed for driving piles up to 40 ft. in length and the pile-driving frame consists of a trussed steel beam, with a balance box at one end and short vertical struts at the other end, to the top of which the leaders are pivoted. The method of fixing the latter is such that piles may be driven on the latter up to 3 in. per foot, or the leaders may be hinged backwards into a horizontal position to clear the running gauge when the machine is traveling. The trussed beam is carried in roller guides and is mounted on a turntable, which allows the pile-driving frame to be moved backwards or forwards and rotate in either direction, so that the piles may be driven at distances varying between 7 ft. and 16 ft. in advance of the leading axle and at any distance up to 18 ft. on either side.



View of Pile-Driver Ready for Moving.

The turntable carrying the pile-driving frame is placed over the centre of the leading bogie and the boiler, engines and gearing are situated at the other end of the carriage, the hoisting ropes for the monkey and pile leading up to the frame through the centre of the turntable. The engines and boiler are rigidly mounted on the carriage platform, and are enclosed in a timber house fitted with sliding doors at each side and a small hinged door in front for giving access to the platform.

The traveling motion is of specially flexible type, so that the drive is unaffected by the extension or compression of the springs. Both axles of one bogie are driven by means of steel gearing and universal joints, and means are provided for disconnecting the traveling mechanism when the machine is required to be hauled by train. The bogies, wheels, axles, draw gear, and brakes are all made to the railway company's standards.



View of Pile-Driver Ready for Work.

The engines are of a special type, being totally enclosed with the working parts running in oil. The cylinders are fitted with a radial reversing motion, and gear is provided for performing the several functions, namely, propelling the machine, raising lowering the leaders, and hoisting the piles and monkey. The boiler is of the locomotive type, and is designed for a working pressure of 110 lb. per square inch. When the leaders are lowered the machine clears the company's construction gauge for rolling stock. A special hand winch is fitted on the pile-driving frame so that piles can be dealt with in the event of any part of the motive mechanism being temporarily out of order, while the slewing gear can also be disconnected and worked by manual labor. The 50 cwt. steam monkey is one of Whitaker Brothers' latest pattern and is capable of delivering from 40 to 60 blows a minute.

EDWARD PARTINGTON PULP AND PAPER COMPANY.

One of the largest business transactions in the history of New Brunswick was closed when deeds for the property of the Gibson Lumber Company were transferred to the Edward Partington Pulp and Paper Company, Limited, while the amount involved is said to be over two million dollars.

The property includes extensive lumber limits and licenses as well as mills, logs and lumber.

The Consolidated Pulp and Paper Company, through Senator N. M. Jones, of Bangor, Maine, had been negotiating to take over both the Gibson and Partington properties, but this has been abandoned, and Mr. Jones will now be associated with the Partington Company as manager of their pulp interests.

The capacity of the St. John pulp mill will be enlarged, and the establishment of another huge pulp mill on Nashwaak River, near Fredericton, will be considered.

WATER AND SEWERAGE SYSTEMS.*

By C. H. Altham.†

The development of modern waterworks began in Paris and London as early as the beginning of the 17th century, but little progress was made until the application of steam to pumping engines, first made in London in 1761. Since 1800 the development has been very rapid, both in Europe and America.

The first works in America for the supply of water to towns were those of Boston, built in 1652. Machinery was first used for pumping water at Bethlehem, Pennsylvania, where the works were put into operation in 1754. The first use of the steam engine was at Philadelphia in 1800, and in New York steam was applied in 1804. The principal development in this country has taken place since 1880, about 98% of all existing works having been constructed since that time. Nearly all towns of 2,000 inhabitants or more now have a public water supply, and the construction of works is progressing rapidly in many smaller towns and villages. While there is more work yet to be done in this direction, the chief work of the future will be in providing increased supplies for the rapidly growing cities and towns of this country, in developing new and better sources of supply and in the improvement of the quality of the existing supplies. There is also much opportunity for the engineer in the management of waterworks, in the direction of reducing cost of operation, prevention of waste and in the improvement of service in many other ways.

The most important use of a public water supply is that of furnishing a suitable water for domestic purposes. For such use the prime requisite is that the water should be pure. The transmission of certain diseases such as cholera and typhoid fever by polluted water is now universally recognized, and the value to the city of a pure supply when compared to one constantly polluted by sewage can scarcely be over estimated.

Another highly important function of a water supply is that of furnishing the necessary flushing water for a sanitary system of drainage. The most satisfactory and economical method yet found for disposing of the organic wastes of a community is by the water carriage system.

Besides furnishing an improved supply from the sanitary standpoint, a public works may often be made to furnish a water which for other reasons will be of greatly increased value to the domestic consumer; such as soft water in place of a hard well water,—a point of very considerable importance to both domestic and commercial users.

A good water supply is also of great value to the manufacturing interests of a town. Many establishments, such as sugar refineries, starch factories, cleaning and dyeing houses, chemical works, etc., require an abundant water supply, and in some cases water of a high degree of purity. The question of water supply indeed often determines the location of factories. Large quantities are also used for operating elevators, for boiler purposes, and for many other uses that may be classed as commercial.

The most important public use of water supply is in extinguishing fires. The economic value of a good fire-protection system is directly shown in the reduced rates of insurance which follow its introduction or improvement. Instead of distributing a heapy fire loss among the people of a community through high rates of insurance it is assuredly much better economy to distribute to the maintenance of a public water-works, which at the same time provides a suitable water for other purposes. To permit of the establishment of a certain class of factories it is absolutely essential that an efficient fire protection be furnished.

Other important public uses of a water supply are in street sprinkling and sewer flushing, in furnishing water for public buildings and for drinking and ornamental fountains. A real value exists in the improved appearance which may be given to a city by the use of water in fountains and for lawns and public parks; and, indeed, all the benefits accruing from a good water supply act indirectly to increase the desirability of a town for many purposes and to enhance the value of the property therein.

I do not intend to quote a lot of uninteresting statistics as to consumption, etc., but one thing does interest us and that is a good and pure source of supply. Our province is fortunate in possessing many beautiful streams of water and many, that besides furnishing water for public use, will be developed for power purposes. As the country is not densely populated the problems of pollution are not difficult, but as the population increases we shall be confronted with some of the difficulties that have and are being experienced by the large cities of the United States and Canada. The greatest objection to our water supply from the rivers is the turbidity of the water during the spring months and while the water may not be injurious it does not look very palatable, and I consider that the water supply for a town cannot be considered complete without an efficient filtration plant, as a plentiful and pure supply of water is an absolute necessity for the health and safety of the town.

Sanitary or Combined Sewers.—About equal in importance with a good water supply is the sewerage system, the sewer being the carrier for all the waste liquids and foul matter from the town.

Modern sanitary engineering especially as regards sewerage and drainage has had almost its entire development since 1850. It was not until 1873 that there was published a comprehensive treatise on sewerage, at about this time also much attention began to be paid in England to sewage purification. It was reserved, however, for America to put sewage purification on the road to a satisfactory scientific solution by the thorough investigations of the Massachusetts State Board of Health, began in 1887 and still under way. In America much was done in the third quarter of the 19th century to advance sewerage engineering through the studies of able engineers in connection with the design of systems for Chicago and other large American cities. About 1880 the separate system of sewage came strongly into prominence in America as advocated by the late Col. Geo. F. Waring and the construction of the Memphis sewers on this system at that time together with their great success in putting a stop to the fearful epidemics, which had so often desolated that city, did much to make sewerage possible for small cities. At present sewers have become so common and so necessary in modern life that towns of 2,000 population or even less are very generally taking up their construction. With the present wide adoption of sewers even by small communities, sewage disposal has come to be of very great importance and is now undergoing great development. Many discoveries remain to be made in this line in which the guiding principles have not yet been so thoroughly worked out as in the construction and maintenance of sewers themselves. The importance and value of the construction of sanitary engineering can hardly be exaggerated, upon them absolutely depends the health of every city. In this connection it should be said that pure water supply and good sewerage are both essential, and that it is impossible to separate the value of one from that of the other. A polluted water supply may

*Read at Union of Alberta Municipalities Convention in Macleod.

†Superintendent of Water and Light for the Town of Macleod.

spread the disease no matter how perfect the sewerage and an abundant water supply is essential to the proper working of sewers. On the other hand without sewers and drains, an abundant water supply serves as a vehicle to enable filth to saturate more deeply and more completely the soil under a city. Cess pools being very dangerous and objectionable for this reason. In addition to direct prevention of communication of disease by unsanitary conditions, modern sewerage facilities are so great a convenience that this advantage alone is usually more than worth the cost, this is shown by the increased selling and rental value of premises supplied with sewerage facilities. No sooner is a partial or complete sewerage system constructed in a town than prospective buyers or renters begin to discriminate severely against property not supplied with modern sanitary conveniences, and persons looking for new locations for business ventures or residence purposes discriminate in like manner in favor of towns having good sewerage.

From these few remarks it seems convincing that no town can afford to economize on the expense of making the water and sewerage systems as perfect as possible, they being so vital to the health and comfort of every inhabitant in a town.

STANDARDIZING OF TELEGRAPH BLANKS, BUSINESS CARDS AND CATALOGUES.

By Carl J. Printz.*

Business correspondence is now invariably made on sheets 8½" × 11", the so-called letter size, regardless of whether the letter is a long one or a short one, and up-to-date firms have also adopted this size for their specifications and tenders. This is done, of course, for the convenience of filing, as it is very hard, in any filing system, to file the "pap" size or to look through a file containing a variety of sizes.

The telegraph companies are slow in adopting the 8½" × 11" size for their blanks, and the reason for this is probably that they have their filing cabinets made for their usual size, but a change to letter size would be exceedingly welcomed by all business concerns, and it will undoubtedly come sooner or later.

As to business cards a standardization is highly desirable and the 3" × 5" size is gradually adopted by persons who use their cards for other purpose than simply an introduction. Business cards are continually referred to by purchasing agents and others as they, in a majority of cases, are substitutes for catalogues, and are much easier filed and looked over —if printed on some standard size.

The 3" × 5" is a convenient size for the vest pocket and it fits any standard filing case.

As business cards of this size generally have descriptive matter printed on both sides, it would be inconvenient to have them locked with the locking-rod in the card case, but as a card with perforations or cut for such locking device will suggest filing, it is found advantageous, and it also distinguishes such cards from the small blotters which are distributed as advertisements.

Catalogues are among the hardest things to file on account of their extreme variety in size and thickness, but even in this line there is a growing tendency to standardizing, and the 8½" × 11" seems to take the lead and will, no doubt, some day be generally adopted.

*Consulting Engineer, Toronto.

THE DISPOSAL OF TORONTO SEWAGE.

The question of the pollution of the Great Lakes is assuming more and more importance. From repeated analyses made during the past few years the amount of chlorine in the lakes appeared to be on the increase. The Board of Water Experts, who have just presented their report on the question of water supply for Toronto, state that if sewage pollution is not stopped or minimized it will in time render the westerly end of Lake Ontario unsafe for use as a public water supply. The Board's comments on the disposal of Toronto sewage are of interest in this connection. The following is abstracted from their report:—

The question of the disposal of the sewage of Toronto has such a close connection with the question of water supply, that it has demanded close investigation by this Board. Present conditions and proposals have been investigated, the results of which are hereto appended. The conclusions of this Board upon the investigation are herewith given:—

Assuming the Toronto sewage to contain 300 parts of dry residue solids per 1,000,000, then a dry weather flow of 45,000,000 gallons per day will represent approximately 60 tons of dry residue solid matter, or 3,000 lbs. per 1,000,000 gallons of sewage.

The amount of solids which will be primarily arrested by the screens will be insignificant.

At Providence, R.I., with gratings 1 inch apart, 41 lbs. per million gallons were retained. At Boston, with similar gratings, the rate was 300 lbs. With gratings .75 inch apart the average rate of retention at the South Metropolitan System for the years 1905-1908 was 324 lbs. At the London Northern outfall sewer in 1897, with similar gratings, 243 lbs. At Berlin, with bars spaced 0.6 inch apart, 212 lbs. were retained.

It can not be assumed that the screening apparatus as proposed for Toronto sewage will remove more than 100 lbs. of dry solid residue per 1,000,000 gallons of sewage. This leaves 2,900 lbs. per 1,000,000 gallons to be removed by sedimentation. Assuming an optimistic conclusion that 30 per cent. of the solids will be removed by sedimentation, then 2,030 lbs. of dry residue per 1,000,000 gallons will continue to enter the lake. This means that approximately 40 tons per day of dry residue will continue to enter the lake after treatment at dry weather flow.

The effluent out-take is to be 60 inches in diameter laid across and under the east end of Ashbridge's Bay for a distance of about 1,830 feet from the tank to the lake shore, and continued into the lake for a further distance of about 3,500 feet, finishing at a point of discharge in about 20 feet depth of water. This point of discharge will be located approximately 26 000 feet (or about 5 miles) to the east of the present water intake mouth, and approximately 24,000 feet (or about 4½ miles) west of the "Dutch Church" at Scarboro' Cliffs.

The total length of the effluent out-take is 5,330 feet. With the lake level at 40 and the tank level of sewage at 51, representing the height of sewage in the inlet channel at three times the dry weather flow, a hydrostatic head of 11 feet is effected, allowing of a maximum discharge of 100 cubic feet of sewage per second, or 1.2 times the dry weather flow at 45,000,000 gallons per day.

It is, therefore, apparent that under the above conditions, while 135,000,000 gallons of sewage are entering the works, only 54,000,000 gallons can be treated, while the balance of 81,000,000 gallons must be dammed back and pass over and through the storm overflow provided at the works direct into Ashbridge's Bay immediately south of the tanks.

It is only when the tanks are taking the dry weather flow at 83 cubic feet per second, with the sewage standing at an elevation of 47.50 in the inlet channel, that equilibrium is

reached and that the effluent out-take is discharging an equal amount of sewage to that which is entering. Any increase in discharging can only be effected by backing up and increasing the head on the effluent out-take and thus increasing velocities and so deleteriously affecting the process of sedimentation.

The general conclusions which may be arrived at from the above statement are as follows:—

(a) That four times the dry weather flow of sewage (taken at 45,000,000 gallons per day, dry weather flow), will arrive at the sewage works.

(b) That the amount of sewage over and above four times the dry weather flow is variable and may reach 22 times the dry weather flow at a rainfall rate of 1.5 inches per hour. That 0.10 of an inch rainfall per hour will produce 5.2 times the dry weather flow. That a storm such as occurred on 27th August, 1911, will produce 60 times the dry weather flow. That for 400 hours of an average year the rainfall will reach or exceed 5.2 times the dry weather flow.

(c) That the sewage of Toronto normally contains about 3,000 lbs. of dry residue solid matter per each 1,000,000 gallons of sewage. That 100 lbs. of these solids will be retained by screening. That a further 870 lbs. will be retained by sedimentation. That 2,030 lbs of solids in comparatively finer particles than that which is retained will continue to enter the lake, or that 60 tons of dry residue matter per day is contained in normal Toronto sewage, and that 40 tons will continue per day to enter the lake at a point 3,500 feet from shore, about midway between the "Dutch" Church and the existing water intake pipe.

(d) That an optimistic view of the capacity of the tanks is that they are only equal to a dry weather flow of 45,000,000 gallons, and that even with this capacity and rate of flow, only 30 per cent. of the solid matter and only the grosser solids will be retained.

With respect to the effect the proposed intercepting sewers and disposal works will have on Lake Ontario water as a source of domestic supply in the neighborhood of Toronto, it must be at once conceded that it is out of the question to anticipate any greater purity of water for a radius of ten miles from the City Hall than has existed heretofore. The continued discharge of storm water by means of the present sewer outlets, the discharge of sewage treated only to the extent of a small proportion of the grosser solids direct into the lake five miles from the water intake, without any attempt to reduce and extinguish the cause of disease infection, will reduce the present nuisance to Toronto Bay and immediate shore neighborhood, but, on the other hand, such will in no way tend to bring about a class of water within ten miles' radius of the city suitable for domestic consumption, unless such water undergoes some efficient process of purification treatment capable of destroying the disease infection due to sewage pollution.

It is now generally conceded that all methods of sewage disposal such as screening, sedimentation and filtration, may remove nuisances which are due to the decomposition of organic matters, that is, nuisances which are apparent to the senses, but that such processes do not entirely and only to a very small extent remove the causes of disease infection peculiar to sewage discharges. In order to render sewage discharges pathogenically harmless, it is necessary that such be disinfected if discharged into a water used as a source of domestic supply.

It is an undoubted fact that dilution of sewage with water tends to its ultimate organic purity and that large bodies of water are capable of dealing with and purifying large quantities of organic matter; on the other hand the causes of disease infection are not so readily acted upon and may be carried for considerable distances. It must, therefore, be concluded that considering the present proposal of the city regarding sewage treatment, the present acknowledged contaminated character of the lake water in the vicinity of Toronto must remain the chief factor in reference to water supply.

IMPORTATION OF CEMENT.

In connection with the tariff reduction on cement, it will be interesting to see how the duty which has heretofore prevailed against United States cement was made up.

Barrels of 350 lbs., at 12½c. per 100 lbs.	.43¾
Bags valued at 40c. per (bbl.) at 20%	.08
Total duty per barrel against American cement	.51¾

Inasmuch as the government has concluded, for the time being at least, to reduce the duty 50 per cent., this would mean that 26c. per barrel will be reduced. Assuming that the price of United States cement at the factory is 60c. per barrel, and that the freight rate is 48c., we would have the following:—

American price per barrel at mill	.60
Freight	.48
Duty	.26
Total price	1.34

So far as the Montreal market is concerned, it would seem that this would have little effect, inasmuch as cement has been quoted here at the factory at 1.35 to 1.45, exclusive of package, and it is much more convenient to purchase from manufacturers on the spot than abroad. It is just possible, however, that the lowering of the duty to 26c. would mean the importation of British cement to some extent, inasmuch as the preferential would reduce this by one-third, which would mean about 17c. as against 34, which has prevailed up to the present.

It seems not unlikely also that 60c. at the factory in the United States is an exceptionally low quotation. Some quotations are 65c., and it is the opinion of many manufacturers that with the additional demand which the lowering of the duty may bring about, United States manufacturers may be able to ask a yet further advance. This, however, may be doubted, as the over-production in the United States is great.

NEW HEALTH OFFICERS IN ONTARIO.

Six of the seven district health officers have been appointed by the Provincial Government. They are:—Dr. D. B. BENTLEY, of Sarnia, for the district comprising Essex, Elgin, Kent, Lambton, Middlesex and Oxford; Dr. T. J. McNALLY, of Owen Sound, for the district comprising Bruce, Dufferin, Grey, Huron, Perth, Wellington and Waterloo; Dr. D. A. McCLENAHAN, of Waterdown, for the district comprising Brant, Haldimand, Halton, Lincoln, Norfolk, Peel, Welland, Wentworth, and York; Dr. GEO. CLINTON, of Belleville, for the district comprising Ontario, Durham, Northumberland, Prince Edward, Hastings, Peterboro', Victoria, Muskoka and Simcoe; Dr. P. J. MOLONEY, of Cornwall, for the district comprising Lennox and Addington, Frontenac, Leeds, Grenville, Stormont, Dundas, Glengarry, Prescott, Russell, Carleton, Lanark and Renfrew; Dr. R. E. WODEHOUSE, of Fort William, for the district comprising the districts of Manitoulin, Algoma, Kenora, Thunder Bay and Rainy River. The officer for the remaining district, comprising the districts of Parry Sound, Nipissing, Temiskaming and Sudbury, has not been named.

The appointments take effect on August 1st, when the doctors report for the prescribed course of study at the University.

PERSONAL.

MR. J. DARLINGTON WHITMORE, after a residence of nine years in Canada, principally spent in the West, passed through Toronto this week on his way to New Zealand.

MR. J. McD. PATTON, who this spring completed his post-graduate year for degree of B.A.Sc., at the University of Toronto, was recently appointed superintendent of waterworks for the city of Regina.

MR. JOHN MacDONALD, formerly a member of the engineering staff of the city of Medicine Hat, has been appointed district engineer for the district of Medicine Hat and Milk River, by the government of the province of Alberta.

COMING MEETINGS.

CANADIAN ELECTRICAL ASSOCIATION.—June 19th-21st. Annual meeting at Ottawa, Ont. Sec'y, T. S. Young, 220 King St. West, Toronto, Ont.

SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION.—June 26th-28th. Annual meeting at Boston, Mass. Sec'y, H. H. Norris, Cornell University, Ithaca, N.Y.

ONTARIO MUNICIPAL ASSOCIATION.—Annual convention will be held in the City Hall, Toronto, on June 18th and 19th, 1912. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ont.

THE UNION OF CANADIAN MUNICIPALITIES.—August 27, 28 and 29. Meeting at City Hall, Windsor, Ont. Hon. Secretary-Treasurer, W. D. Lighthall, K.C.

CANADIAN FORESTRY ASSOCIATION.—Convention will be held in Victoria, B.C., Sept. 4th-6th. Secy., James Lawler, Canadian Building, Ottawa.

CANADIAN PUBLIC HEALTH ASSOCIATION.—Second Annual Meeting to be held in Toronto, Sept. 16, 17 and 18.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Annual Assembly will be held at Ottawa, in the Public Library, on 7th October, 1912. Hon. Sec'y, Alcide Chaussé, 5 Beaver Hall Square, Montreal, Que.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE: Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—177 Sparks St. Ottawa. Chairman, S. J. Chapleau, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings,

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving; Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, C. E. Cartwright; Secretary, W. Alan, Kennedy; Headquarters: McGill University College, Vancouver.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1290.

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydonejack; Meets every first and third Friday of each month, October to April, in University of Manitoba, Winnipeg.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION.—President, Chas. Hopewell, Mayor, Ottawa; Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm. Mason, Bon Accord, Alta. · Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, W. Sanford Evans, Mayor of Winnipeg; Hon. Secretary-Treasurer, W. D. Lighthall, K.C., Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, Mayor Mitchell, Calgary.; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALTIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewit, General Manager Consumers' Gas Company, Toronto; J. Keillor, Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President, J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary. H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Jas. Anderson, Gen. Mgr., Sandwich, Windsor and Amherst Railway; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, Killaly Gamble, 703 Temple Building, Toronto.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, J. E. Ganier, No. 5. Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, F. S. Baker, F.R.I.B.A., Toronto, Ont.; Hon. Secretary, Alcide Chausse, No. 5. Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman; Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, J. P. McRae; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Wm. Pierce, Calgary; Secretary-Treasurer, John T. Hall, Brandon, Man.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, 115 Phœnix Block, Winnipeg, Man. Second Monday, except June, July and August, at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc.
Printed forms for the purpose will be furnished upon application.

PLANS AND SPECIFICATIONS ON FILE.

The following Plans (P.) and Specifications (S.) are on file for reference only unless otherwise noted at the office of The Canadian Engineer, 62 Church Street, Toronto:—

Bids close		Noted in issue of
6-17—Electric Generating Station Equipment, Bassano, Alta.	(S.)	5-30
7-3—Storm Drain, Orillia, Ont.	(P. & S.)	6-20
7-1—Boilers, 300-h.p., Verdun, Que.	(S.)	6-20

(Bassano specifications also on file at the office of The Canadian Engineer, Montreal, and the Engineers, Messrs. Bowring & Logan, 322 Donald St., Winnipeg).

TENDERS PENDING.

In Addition to Those in this Issue.

Further information may be had from the issues of The Canadian Engineer referred to.

Place of Work.	Tenders Close.	Issue of.	Page.
Arden, Man., bridge	July 3.	June 13.	78
Barrie, Ont., public buildings	June 27.	June 13.	67
Boswell, B.C., pile bent wharf	July 2.	June 6.	68

TENDERS.

Calgary, Alta.—Tenders for one 500 K.W. synchronous motor generator, to be delivered, erected and installed in the city, will be received up to noon of June 26th, 1912, by the City Commissioners. Specifications may be obtained from the Commissioners' office. J. M. Miller, City Clerk.

Carleton Place, Ont.—Tenders will be received by the Sewers and Water Commission of the municipality of Carleton Place, Ont., up to noon of July 1st, 1912, for the construction and supply of all materials in connection with about five miles of sewers and about five miles of watermains. Consulting Engineer, T. Aird Murray, Toronto; Resident Engineer, B. G. Michel, Carleton Place, Ont. (See advertisement in The Canadian Engineer of June 27th.)

Fort William, Ont.—Tenders for the construction of a concrete and tile sewer on Marks Street, will be received at the office of the City Clerk, until July 5th, 1912. Plans, etc., can be obtained at the office of John Wilson, City Engineer.

Kingston, Ont.—The Board of Works are calling for tenders for asphaltic block pavements to be laid on a number of streets in the city.

London, Ont.—Tenders for the construction of about 900 feet of concrete breakwater on the Medway River. Specifications, etc., at the office of F. W. Farncomb, Consulting Engineer, London. (See advt. in Canadian Engineer.)

Moose Jaw, Sask.—Tenders for the supply of material and erection of City Hall Annex will be received by the City Commissioners, Moose Jaw, up to noon of June 20th, 1912.

Napanee, Ont.—Tenders for the completion of about 10,000 lineal feet of tile sewers with manholes and junctions, will be received until noon of June 25th, 1912. Sewers to be constructed of 9 in., 12 in., and 15 in. standard vitrified sewer pipe. Plans and specifications may be seen at the office of the engineer, George C. Wright, Kingston, Ont. W. A. Grange, town clerk, Napanee, Ont.

Norwood, Ont.—The Department of Militia and Defence, Ottawa, is open to receive tenders for the construction of a new Drill Hall at Norwood, until July 3rd. Specifications may be seen at the offices of the Officer Commanding 3rd Division, Kingston, Ont.; Officer Commanding "E" Company, 40th Regiment, Norwood, Ont., and the Director of Engineer Services, Headquarters, Ottawa.

Orillia, Ont.—Tenders for the construction of approximately 16,200 lineal feet of sanitary sewers will be received until July 3rd, 1912. Plans, etc., on file in the Town Engineer's office, Orillia. (See advt. in The Canadian Engineer).

Orillia, Ont.—Tenders for the construction of approximately 2,450 lineal feet of reinforced concrete box storm drain and sidewalk top, will be received until July 3rd, 1912. Plans and specifications on file at the office of The Canadian Engineer, 62 Church St., Toronto, and at the Town Engineer's office, Orillia. (See advt. in The Canadian Engineer).

Ottawa, Ont.—Tenders will be received until June 25th, 1912, for a boom dredge required for the Rideau Canal. Plans, etc., can be obtained on application to L. K. Jones, secretary, Department of Railways and Canals, Ottawa.

Ottawa, Ont.—Tenders for the construction of fittings, finish, etc., at the Armoury, Niagara Falls, Ont., will be received until June 25th, 1912. Plans, etc., can be obtained on application to Mr. Geo. Seales, Clerk of Works, New Armoury, Niagara Falls, Ont., and at the office of R. C. Desrochers, Secretary, Department of Public Works, Ottawa.

Ottawa, Ont.—Tenders for certain alterations and additions to the Elkhorn Industrial School Buildings, will be received up to noon of July 9th, 1912. Plans and specifications may be seen at the Indian Office, Winnipeg; at the School, Elkhorn, and at the Postoffices at Brandon and Virden. J. D. McLean, Assistant Deputy and Secretary, Department of Indian Affairs, Ottawa.

Ottawa, Ont.—Tenders will be received until noon of June 22nd, 1912, for repairs to the Rifle Range at Pointe aux Trembles, P.Q. Plans and specifications may be seen at the offices of the Officer Commanding the 4th Division, Montreal, P.Q., and the Director of Engineer Services, Headquarters, Ottawa. Eugene Fiset, Col., Deputy-Minister, Department of of Militia and Defence, Ottawa.

Ottawa, Ont.—Tenders for the construction of two 95 cubic yards' capacity wooden hopper scows, will be received until July 3rd, 1912. Plans, etc., at the Department of Public Works, Ottawa; offices of G. G. Scovil, Esq., Superintendent of Dredges, St. John, N.B.; G. M. Graham, Esq., Superintendent of Dredges, New Glasgow, N.S.; and J. N. McDonald, Esq., Superintendent of Dredges, Charlottetown, P.E.I. R. C. Desrochers, Secretary, Department of Public Works, Ottawa.

Ottawa, Ont.—Tenders will be received at the Department of Public Works, Ottawa, until July 4th, 1912, for the construction of a wharf at Brundage's Point, Westfield, King's County, N.B. Plans and specifications to be seen on application to J. K. Scammell, Esq., District Engineer, Chatham, N.B., and at the Department of Public Works, Ottawa.

Ottawa, Ont.—The Department of Railways and Canals, Ottawa, will receive tenders until August 1st, 1912, for the construction of the section of the Hudson Bay Railway from Thicket Portage to Split Lake Junction. Plans, etc., at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa, and at the office of the Chief Engineer of the Hudson Bay Railway, Winnipeg.

Ottawa, Ont.—Tenders for dredging required at Port Arthur, Ont., will be received until July 2nd, 1912. Full particulars can be obtained on application to R. C. Desrochers, Secretary, Department of Public Works, Ottawa.

Ottawa, Ont.—The Department of Public Works, Ottawa, is open to receive tenders until July 10th, 1912, for the construction of a wharf at Cache Bay, District of Nipissing, Ont. Plans, etc., at the Department, and at the office of J. G. Sing, Esq., District Engineer, Confederation Life Building, Toronto, and on application to the Postmaster at Cache Bay, Ont.

Ottawa, Ont.—The Department of Public Works are calling for tenders for dredging required at Perry Point, N.B., tenders to be received until June 26th, 1912. Combined specifications and form of tender can be obtained on application to the Secretary, R. C. Desrochers, Department of Public Works, Ottawa.

Ottawa, Ont.—Tenders are invited for the construction of quarantine buildings upon the quarantine grounds at Windsor, Ont. Tenders to be in Ottawa by noon, July 8th. Particulars may be obtained either from Inspector F. A. Jones, Windsor, or from the Acting Veterinary Director General, Ottawa. A. L. Jarvis, Asst. Dep. Minister and Secretary of Agriculture, Dept. of Agriculture, Ottawa.

Plans, etc., at the Indian Offices, at Winnipeg and Selkirk, and at the offices of the Indian Agents at Kenora and Port Arthur.

Ottawa, Ont.—The Department of Militia and Defence will receive tenders up to noon of July 2, 1912, for the construction of a new Drill Hall at Omemee, Ont. Specifications may be seen at the offices of the Officer Commanding 3rd Division, Kingston, Ont.; Officer Commanding "D" Company, 46th Regiment, Omemee, Ont., and the Director of Engineer Services, Headquarters, Ottawa.

Ottawa, Ont.—The Department of Railways and Canals, Ottawa, will receive tenders until August 1st, 1912, for the construction of the section of the Hudson Bay Railway from Thicket Portage to Split Lake Junction. Plans, etc., at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa, and at the office of the Chief Engineer of the Hudson Bay Railway, Winnipeg. (See advt. in Canadian Engineer.)

Ottawa, Ont.—Tenders for the erection of an operating house and double dwelling, at Alert Bay, at Cormorant Island, B.C., will be received until noon of July 1st, 1912. Plans, etc., at the office of the Superintendent of Radio-Telegraph Branch of Department of Naval Service, Ottawa, or at the office of the District Superintendent or Radio-Telegraph Service, Victoria, B.C., and office of the Postmaster at Alert Bay, Cormorant Island, B.C. G. J. Desbarats, Dep. Min., Dept. of Naval Service, Ottawa.

Regina, Sask.—Tenders will be received until June 21st, 1912, for the following:—

(1) Two reinforced concrete bridge abutments for a bridge over the Battle River, west of Battleford.

(2) Two reinforced concrete bridge abutments and two small reinforced concrete bridges west of Rosthern.

Plans, etc., may be obtained on application to A. J. McPherson, Chairman, Board of Highway Commissioners, Regina, Sask.

Saskatoon, Sask.—Plans have been filed and tenders are now being called for the new C.P.R. Building, which will involve an expenditure of over $200,000.

Shoal Lake, Man.—Tenders for the construction of a brick and stone municipal hall for the municipality of the village of Shoal Lake, will be received up to noon of June 25th. Plans, etc., at the office of the architect, Hooper and Hooper, 303 McIntyre Block, Winnipeg, or at the office of F. M. Dobbs, sec.-treas., municipality of village of Shoal Lake, Man.

Toronto, Ont.—Tenders will be received until noon of July 22, 1912, for the complete supply and installation of three hundred and seventy-one (371) opera chairs in St. Lawrence Hall, Toronto. Specifications, etc., at the offices of the Property Department, City Hall, Toronto. G. R. Geary (Mayor), chairman Board of Control, City Hall, Toronto.

Toronto, Ont.—Tenders for the construction of dairy barns to be erected on the grounds of the Ontario Agricultural College, Guelph, will be received up to noon of June 29th, 1912. Plans and specifications can be seen at the office of the Superintendent, Agricultural College, Guelph, and at the office of H. F. McNaughten, secretary Department of Public Works, Province of Ontario, Toronto.

Toronto, Ont.—Tenders for the laying and jointing of a 36-in. water main on Front Street, with connections, will be received up to noon of July 2nd, 1912. Specifications may be seen at the office of the Commissioner of Works, Toronto. G. R. Geary (Mayor), chairman, Board of Control, City Hall, Toronto.

Toronto, Ont.—Tenders for the laying and jointing of a 36-in. water main on Front Street, with connections, will be received up to noon of July 2nd, 1912. Specifications may be seen at the office of the Commissioner of Works, Toronto. G. R. Geary (Mayor), chairman, Board of Control, City Hall, Toronto.

Vancouver, B.C.—Competitive plans will be received up to noon, June 28th, 1912, for the proposed Georgia-Harris Viaduct. Specifications, plans and conditions of competition may be obtained at the office of the City Engineer, City Hall. Wm. McQueen, City Clerk, Vancouver, B.C.

Verdun, Quebec.—Tenders will be received at the Town Hall, Church Avenue, Verdun, until July 1st, 1912, for the supply and installation of two 300 horse-power water tube boilers. Specifications, etc., at the Town Engineer's office, Verdun, and also at the office of The Canadian Engineer, 62 Church Street, Toronto. (See advt. in The Canadian Engineer).

Winnipeg, Man.—Tenders for the manufacture and delivery f.o.b., Winnipeg, of approximately 70,000 duct feet of single vitrified clay conduit, will be received up to noon of June 21st, 1912. Full particulars may be obtained at the office of the City Light & Power Department, 54 King Street. M. Peterson, secretary, Board of Control Office, Winnipeg.

Winnipeg, Man.—Tenders will be received until June 20th, for all the trades required in connection with the erection and completion of a fireproof office building, for the Great West Permanent Loan Company. J. H. G. Russell, architect, McArthur Building, Winnipeg.

CONTRACTS AWARDED.

Berlin, Ont.—The contract for the new school building was awarded to Mr. Henry Braniff, his tender being the lowest. The cost will be in the neighborhood of $23,000.

Cheticamp, N.S.—Dredging; contractors, Vivian T. Bartram, 117 Stair Building, Toronto.

Hamilton, Ont.—The Des Moines Manufacturing Company, of Des Moines, Iowa, have received the contract to construct a water tower to cost $4,990.

Hillsborough, N.B.—Post office fittings; the J. T. Schell Company, of Alexandria, Ont.

Barrett Specification Roofs

On the "Concrete City."

IN the illustration below, the Turner Construction Company of New York, has brought together in a scale drawing an accurate representation of most of the important modern concrete buildings which they have erected during the past nine years, at an approximate cost of $12,000,000.

It is an imposing display of best types of modern construction—"*a concrete city*" indeed—scientifically designed for maximum service at minimum cost and minimum maintenance.

It is significant that 95 per cent. of the entire roof area is covered with the Barrett Specification type of roofing. The figures are as follows:

Barrett Specification type of roofs	1,490,523 sq. feet
Plastic Roofings	14,714 sq. feet
Slate Roofings	21,640 sq. feet
Tile Roofings	5,619 sq. feet
Ready Roofings	38,381 sq. feet
Copper Roofings	6,355 sq. feet
All other kinds	7,448 sq. feet

It is important to remember that while all these buildings were constructed by the Turner Construction Company, the specifications were drawn by a large number of architects and engineers.

Barrett Specification Roofs were almost unanimously selected for one reason only, namely that they would give *better* service at *lower cost*, than any other roof covering.

Barrett Specification Roofs require no painting or similar attention—in other words, there are no maintenance costs. They will last upwards of 20 years without any care.

The superior economy of Barrett Specification Roofs justifies their adoption not only on big first-class concrete buildings, but on every flat roofed building from a tenement to a skyscraper—from a small mill to a modern manufacturing plant costing millions. But be sure it's a real Barrett Specification Roof. The only way to be sure is to incorporate The Barrett Specification in full in your plans.

Copy of The Barrett Specification free on request. Address our nearest office.

THE PATERSON MANUFACTURING CO., LIMITED

MONTREAL TORONTO WINNIPEG VANCOUVER ST. JOHN, N.B. HALIFAX, N.S.

Kenora, Ont.—Fire hall; Messrs. S. C. Sharman and F. Gilbert, of Kenora, Ont. Price, $20,875, which covers all trades except heating.

Lethbridge, Alta.—The tenders submitted for the construction of the car barn and sub-station for the street railway system were as follows: Hotson and Leader, $51,410; Lussier Construction Co., $39,931; Smith Bros. and Wilson, $39,100. The contract was awarded to the latter firm.

Maple Creek, Sask.—The contract for the 7,000 yards of cement sidewalks, has been awarded to Mr. C. H. Campbell, Cavallier, N.D., his price being 19c. per sq. foot for sidewalks and 37c. per lineal foot for curb.

Moose Jaw, Sask.—Sewer pipe and specials; the Saskatchewan Glass & Supply Co., Moose Jaw.

Nanaimo, B.C.—Interior fittings, post office; the Berlin Interior Hardwood Co., Ltd., of Berlin, Ont.

Oakville, Ont.—The contract for the building of the high level bridge over the creek at Cemetery Hill, near Oakville, has been awarded to Mr. A. J. Gibson, of Oakville.

Ottawa, Ont.—Additions and alterations to fuel testing building; contractor, A. G. Marshall, 5 O'Connor Street, Ottawa.

Port Arthur, Ont.—The contract for the Hill Street Fire Hall has been awarded to the Alberta Land Co. Price, $22,000. H. J. Powers, Engineer.

The contract for the twelve-room school on Prospect Avenue, has also been awarded to the Alberta Land Company. Price, $75,000.

Saskatoon, Sask.—Messrs. E. M. Joyl and Company have secured a contract to supply 170,000 ties to Messrs. McArthur and Boyd to be used on the Hudson Bay Railway.

Saskatoon, Sask.—Messrs. Hoge & Marr, have received a contract to construct a moving picture theatre on 20th Street East. Mr. P. L. Sommerfeld, civic alderman, is a member of the company.

Stratford, Ont.—At a meeting of the market and hall committee, the tender of Mr. William Daly, for the market shelter at $12,070, was accepted.

Ste. Therese de Blainville, Que.—The work of installing a waterworks system to cost $75,000 for the Aqueduct Company of Blainville, Blainville, Que., is being done by the owners of the company under the supervision of Engineers Ouimet and Lesage, St. Lawrence Boulevard.

Toronto, Ont.—Messrs. J. E. Webb Company, general contracting, have been awarded the contract for the masonry work for the American Hat Frame Company, to be built at the corner of Bathurst and Wellington Streets. Material used will be concrete, pressed brick and steel.

West Toronto, Ont.—Messrs. Orr Brothers have been awarded the contract for the construction of a retaining wall at Annette School. The cost of this work is placed at $7,125.

Winnipeg, Man.—The National Construction Company have been awarded the contract for the erection of the new law courts, their bid being $760,000.

Winnipeg, Man. — Messrs. Clayton Brothers are the builders and C. Bridgeman the architect for the erection of two large apartment blocks involving an outlay of $252,000.

LIGHT, HEAT AND POWER.

Brockville, Ont.—The municipal gas and light committee have recommended that a number of additional incandescent electric lamps be placed on certain street corners; many of these are to replace gas lamps now in use. Mr. J. H. Bryson is the engineer of Brockville.

Northern Canada.—Messrs. E. M. Joyl and Company have secured a contract to supply 170,000 ties to Messrs. McArthur and Boyd to be used on the Hudson Bay railway. The contract calls for delivery of the ties early next October at which time the railway contractors expect to be in a position to complete that part of the road which is now being graded.

Penticton, B.C.—The council of this municipality will call tenders on a 200 h.p. Deisel engine to be used as motive power in the lighting plant of the town.

Toronto, Ont.—If the approval of the Fire and Light Committee is shown the Hydro-Electric Department will put a few flaming arc lamps at the railway crossing on Bay Street.

Welland, Ont.—A report states that the estimate of the Hydro-Electric Commission for a lighting system for this municipality is given at $45,000, inclusive of cluster lights.

GARBAGE, SEWAGE AND WATER.

East Toronto, Ont.—The ratepayers in a portion of this section are petitioning for annexation and an extension of the municipal water system. They claim their wells have failed them.

Brockville, Ont.—The municipal fire and light committee have recommended that the mains in the vicinity of the James Smart Manufacturing Co. be extended and additional hydrants for fire protection be connected to the same. Mr. J. H. Bryson is the engineer of this municipality.

Saskatoon, Sask.—The new system of rapid water filtration has been given a try-out with complete satisfaction.

St. Thomas, Ont.—The City Engineer has reported on the cost of a proposed 20-inch steel water main from the water works to Balaclava Street. He estimates the cost of this work at $13,000. M. H. Baker, City Engineer.

Toronto, Ont.—Dr. Hastings, municipal Medical Health Officer, has reported on his requirements for the bacteriological treatment of the sewage effluent. He has been instructed to install two chlorinating plants. There is a probability of slow filtration beds being added to the equipment.

BUILDINGS AND INDUSTRIAL WORKS.

Berlin Ont.—The management of the W. G. & R. Shirt and Collar manufacturers will erect a new building during the coming season.

Berlin, Ont.—The municipal council have looked with favor on a proposed rubber manufactory. If this is proceeded with two five story buildings will be erected and 1,000 h.p. required from the Hydro-Electric Commission.

Guelph, Ont.—The Ontario Agricultural College officials will erect two new buildings during the coming season.

Edmonton, Alta.—Mr. Kenneth McLeod is having plans prepared for a nine story office building to cost $500,000. Mr. John T. Gow, of Spokane, is the architect for this work.

Montreal, P.Q.—The congregation of the Church of St. Irene will spend the sum of $125,000 on the construction of a new building. The Rev. Father Bereard is the rector of this parish and the architects are Messrs. McDuff and Lemieux.

Peterborough, Ont.—The Board of Trustees of the Nicholls Hospital have decided to erect two new buildings. One being 90 x 40 feet will provide accommodation for 45 beds the other will be used for laundry purposes.

Regina, Sask.—The municipal School Board will submit a by-law to the ratepayers calling for an issue of debentures of $275,000 to be used for school building purposes.

Saskatoon, Sask.—Messrs. Adams Bros.' Harness Company, Limited, of Toronto, are planning to erect a large building in this city. Mr. F. W. Adams, Winnipeg, may be addressed in the matter.

Saskatoon, Sask.—The management of the King George Hotel are preparing to erect a three story annex on 2nd Avenue.

Tormorden, Ont. — The congregation of St. Andrew's Church have approved plans for an addition to their building which will double the seating capacity. Mr. Fred. Smith is a member of the finance committee. Todmorden is near Toronto.

Toronto, Ont.—The Canadian National Exhibition has secured a permit to erect a $35,000 entrance to Exhibition Park, comprising pylons and gates.

Toronto Ont.—The Municipal Works Committee have adopted the so-called terrace route for the proposed Bloor Street viaduct, as favored by the special committee. The estimated cost is $2,221,760. It will cost $8,000 to make the necessary preliminary borings.

St. John, N.B.

WETTLAUFER BROS.
316 Lagauchetiere St., W.,
Montreal, Que.

Toronto, Ont.—A Dominion Government purchasing agent has secured an option on property at the south-west corner of Saulter Street and Queen Street East. It is said that the property is wanted as a site for the new post office, which will cost about $200,000.

West Toronto, Ont.—The General Fire Extinguisher Company has taken out a permit for a two-story warehouse in Dundas Street near Chelsea Avenue. It will cost $40,000.

Wetaskiwin, Alta.—Construction work has been started on a new factory for the Vulcan Automobile Company.

BRIDGES, ROADS AND PAVEMENTS.

Brockville, Ont.—There is a probability of Main Street being paved at a cost of $53,000. Mr. J. H. Bryson is the engineer of this municipality.

Toronto, Ont.—As a means of lessening the traffic on Queen Street the municipal Works Committee have recommended that Sydenham Street be extended westerly to Shuter Street. The estimated cost of this work is given as $65,000.

Toronto, Ont. — The Works Commissioner will confer with the proper railway officials on the matter of constructing a bridge over the tracks near the ferry wharves on Bay Street.

Victoria, B.C.—The City Engineer will experiment on the dust laying properties of oil on the streets of this city.

FIRES.

Crescent Valley, B.C.—The planing mill of the British Canadian Lumber Company was destroyed by fire. Crescent Valley is near Nelson.

TRADE ENQUIRIES.

The following were among the inquiries relating to Canadian trade received at the office of the High Commissioner for Canada, 17 Victoria Street, London, S.W., during the week ending June 3rd, 1912:—

A Welsh firm of mineral water manufacturers desire to appoint as their agents a first-class Canadian house having branches all over the Dominion.

A London firm desire the representation of a Canadian wood pulp manufacturer.

A London correspondent is prepared to negotiate with Canadian manufacturers for the sole right to manufacture in the Dominion certain specialties in which he is interested, and which include paints, enamels, soaps, varnishes, soluble oil, distempers, disinfectants, etc.

A North of England firm of glass manufacturers are considering the appointment of Canadian agents.

A London firm make inquiry for the names of Canadian manufacturers of maple meat skewers.

From the branch for City Trade Inquiries, 73 Basinghall Street, E.C.:—

A Nottingham company manufacturing laces of all classes are open to consider the appointment of responsible resident agents in the principal Canadian centres.

A Yorkshire company manufacturing wire for brushes, meters, mattresses, cloth, and all purposes except fencing; also wire ropes, twines, and engineers' supplies, wish to make arrangements for the sale of their goods in Canada.

PATENTS.

The following is a list of patents recently issued through the agency of Messrs. Ridout & Maybee, Manning Chambers, Toronto, Canada:—B. R. Seabrook, tops for cans and the like (case 1); B. R. Seabrook, tops for cans and the like (case 2); J. T. Thompson, display devices; W. R. D. Innes, railway sleepers (tie); John Little, rail placing machine; Fred. McRea Bawden, molds for pneumatic tire covers.

United States:—Clifford Guise, swivel; George Fulton, wooden floor coverings; H. E. T. Haultain, weight recording mechanism; H. E. T. Haultain, registering weighing apparatus.

OBITUARY.

E. H. Keating, former municipal engineer of Toronto and later general manager of the Toronto Railway Company, died at his home, 9 Castle Frank Crescent, Toronto, on June 18th last.

Mr. Keating was a native of Halifax, Nova Scotia, and received his early education at the Dalhousie University and the Chicago Academy, after which he studied engineering under Mr. George Whiteman, Provincial Government Engineer of Nova Scotia, and Sir Sandford Fleming.

In his earlier engineering career Mr. Keating was assistant engineer of the Pictou Extension Railway in Nova Scotia, chief draftsman of the Windsor and Annapolis Railway, contractors' engineer for the European and North America Railway, N.B., assistant engineer of different divisions of the Intercolonial Railway, division engineer in charge of exploration for the Canadian Pacific, City Engineer of Halifax, N.S., and also engineer of the Halifax graving dock.

It was while City Engineer of Duluth that the then Mayor, R. J. Fleming, invited Mr. Keating to Toronto to become City Engineer, which position he held from 1892 to 1898.

Mr. Keating was recently honored by the Institution of Civil Engineers of Great Britain. He is a Past President of the Canadian Society of Civil Engineers, a members of the Engineers' Club, Toronto, and the American Society of Civil Engineers.

"ROCMAC" MACADAM BINDER.

Power was turned on at the new mill of the Rocmac Road Corporation at Thorold, Ont., last week and this firm is now prepared to fill orders for Rocmac solutions made in Canada.

Although distinctly a Canadian Company, the Rocmac Road Corporation has had a mill in operation at Tonowanda, N.Y., for over a year, and has met with considerable success in New York State. Originally Rocmac was an English road and was first laid in Halifax, England, on the Skircoat Green Road, in 1907. The results on this first road have been excellent, especially in contrast to an adjoining length of ordinary macadam. Rocmac has also worn well on roads in the United States and Canada and has shown up particularly well on a strip of road in Victoria Park, near the Horseshoe Falls, where it is almost continuously wetted by the spray from the falls.

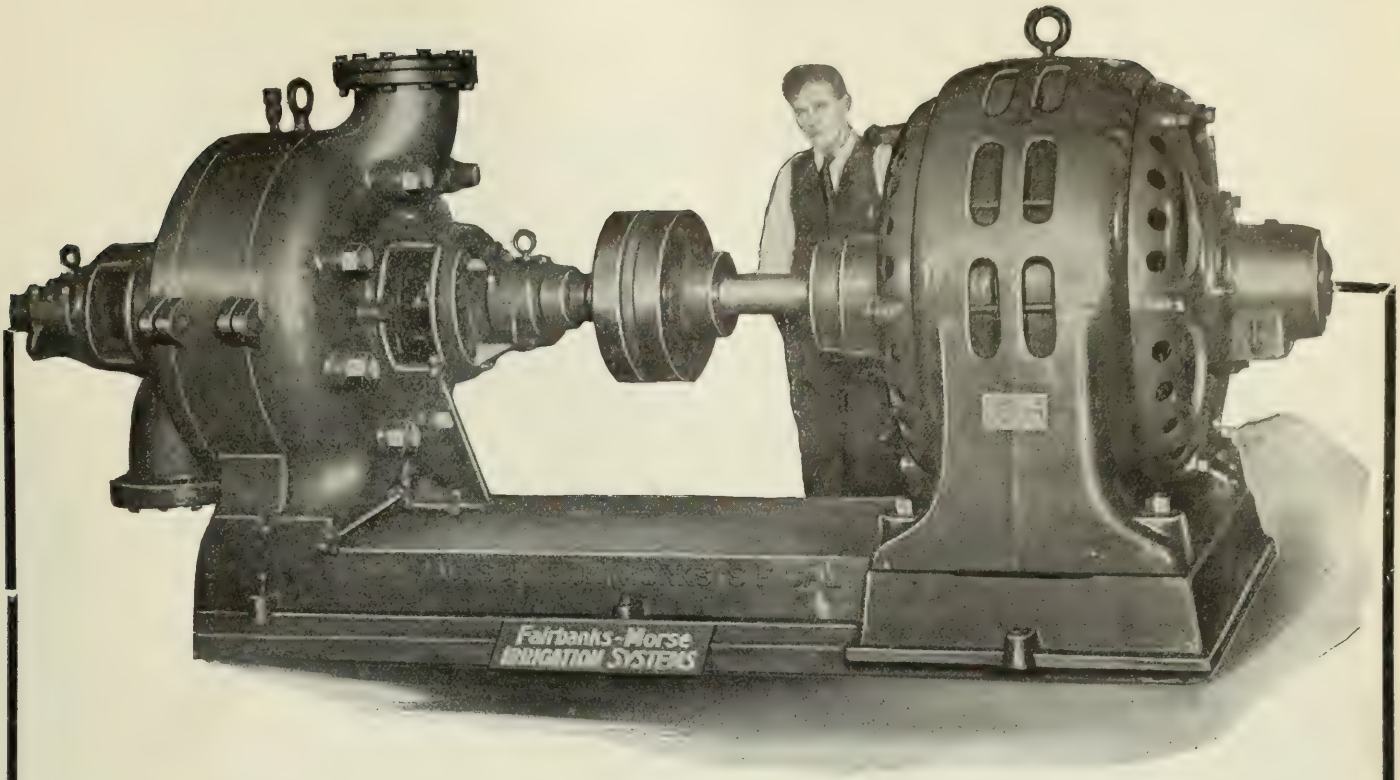
The chief difference between Rocmac and the ordinary macadam is in the binding material. The requirements of a good road are far more exacting to-day than in Macadam's time, and automobiles require a dustless, durable road, formed with a binder which will not disintegrate or deteriorate and which eliminates, or greatly reduces, maintenance charges. It is said that the Rocmac solution fulfils these requirements of a good binder.

The materials used in the construction of Rocmac are limestone, containing a specified proportion of carbonate of lime, crushed to pass a ¼" screen; any hard rock ordinarily used for macadam roads, preferably trap or granite of a size known as No. 2 or No. 3, mixed in about equal proportions of each; and the Rocmac chemical solutions.

The method of building the road is to form a matrix by thoroughly mixing the limestone dust with the solution; this matrix is laid upon the road and the macadam is placed upon the top of it and rolled in until the matrix entirely fills up the interstices and comes to the surface.

When the road has become thoroughly packed by the rollers, a grout appears from the matrix below, so proving that all cavities have been filled. A thin coating of limestone is spread over the road to absorb the excess of solution and to form a cushion for the horses' feet while the process of setting goes on. Traffic is not impeded during construction.

The Rocmac solution is a silico-saccharate. It contains no asphalt, pitch, tar or oil and is entirely harmless to surrounding property during the laying or after the completion of the road. There is no unpleasant odor or damage to vegetation, vehicles or clothing. The surface of the road when finished has the appearance of an ordinary macadam road. A point in favor of Rocmac which will be thoroughly appreciated by Canadian engineers in some sections of the country is that it can be laid in any weather.



The Largest Direct Connected Centrifugal Pumping Unit in British Columbia.

The Vancouver Power Company have recently installed at their works at Coquitlam Dam, B.C., the largest direct connected centrifugal pumping unit in British Columbia. This outfit is to operate in parallel with a number of other pumps that are to furnish water under pressure for sluicing into place the material for their new dam.

This pump is a 10-inch, class "F," two-stage centrifugal, with bronze inpellers and renewable bronze diffusion vanes. It has a normal capacity of 1833 imperial gallons per minute when operating at 1160 r.p.m. against a total head of 355 feet or an equivalent pressure of 154 lbs. per square inch. It is mounted on a common sub-base with a 300 h.p. type "B," Fairbanks-Morse squirrel cage, induction motor, 2200 volts, 60-cycle, 3-phase, 1160 r.p.m. at full load, being direct connected thereto by means of a flexible leather link coupling

The motor possesses a feature in rotor construction that is unique. The end rings are welded on to the rotor bars by a new process, making a perfect joint, free from the troubles common to the purely mechanical or riveted joint, such as oxidation, working loose, and solder-throwing. This improvement marks a long step forward in the elimination of rotor trouble.

Our Vancouver Branch supplied and assembled this complete pumping unit. We are in a position to quote on the necessary equipment for any pumping requirements on receipt of specifications.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from The Canadian Engineer for small fee.

16270—April 10—Dismissing application of town of Battleford, Sask., re C.N.R. branch line passenger service.

16271—April 10—Dismissing complaint of Namaka Farmers' Association No. 122, of Namaka, Alta., re mail service by C.P.R.

16272—March 16—Directing C.N.O. Ry to construct foot subway of concrete through property of Deaf and Dumb Institute at station [illegible], near Belleville, Ontario.

16273—April 9—Approving revised location of C.P.R. Lacombe Easterly Branch, mileage 100.07 to 146.10, Alberta.

16274—April 10—Authorizing C.P.R. to reconstruct bridge No. 30.5 on its Temiskaming Subdivision.

16275—April 11—Amending Order 15995 of Feb. 16, 1912; by substituting "1-2 George V., Chapter 22, Section 10" for "8-9, Edward VII., Chapter 32, Section 10" in recital and operative parts of Order.

16276—April 11—Postponing effective dates of M.C.R. Tariff, C.R.C., No. 1874; G.T.R., C.R.C., No. E. 2376, as amended by Supp. No. 1; Wabash R.R., C.R.C., No. 566, as amended by Supp No 1; advancing rates on anthracite coal, Niagara Frontier to Canadian points.

16277—April 11—Authorizing South Ontario Pacific Rly. Co. (C.P.R.) to construct its Guelph Jct. to Hamilton Branch underneath power wires of Hydro-Electric Power Commission at mileage 13.32, from Guelph Jct.

16278—April 9—Approving locations of 8 G.T.P. Ry. stations in Coast and Cassiar Districts, British Columbia.

16279—April 11—Authorizing G.T.P. B.L. Co. to operate trains over crossing of its Melville-Regina Branch with C.P.R. Main Line in Sask. account interlocker completed.

16280—April 11—16281—April 12—Approving location of C.N. Alberta Ry., mileage 166.01 to 192.83, and to occupy portion of right-of-way of G.T.P. Ry. about mileage 185.5; and approving location from mileage 192.83 to 222.79, Alberta.

16282—April 12—Authorizing C.N.R. to construct bridge across Pembina River in S.W. ¼ Sec. 29, Twp. 53, R. 7, west 5 M.

16283—April 12—Approving revised location of C.N.O. Ry. in Twp. of Ferris, Dist. of Nipissing, mileage 339.5 to 340.72.

16284—April 12—Authorizing C.N.R. to construct bridge across McLeod River, in west half of Sec. 33, Twp. 52, R. 17, W. 5 M.

16285—April 10—Authorizing Esquimalt & Nanaimo Ry. (C.P.R.) to take lands for railways purposes Lots 54 and 55 of Lime Bay, Sec. 31, Victoria West, in British Columbia.

16286-87—April 11—16288-89—April 10—Authorizing C.P.R. to construct spurs for the Alsip Brick, Tile and Lumber Co., Ltd., at Parish, Lot No. 71, St. Boniface, Man.; for Wolverton Milling Co., Ltd., at Wolverton, Ont.; for H. Hilton & Sons, city of Winnipeg, Man., and for Ballast Pit, near Marquette, Man., and to cross 4 highways to same.

16290—April 11—Authorizing C.N.R. to cross public road between S.E. ¼ Sec. 3, T. 39, and N.W. ¼ of Sec. 33, T. 38, R. 27, W. 4 M.

16291-92—April 11—Authorizing C.N.O. Ry. to cross public roads (2) in Twp. of Fitzroy, County Carleton, Ontario.

16293-94-95-96—April 12—Authorizing C.P.R. to reconstruct 5 bridges on its McLeod, Sherbrooke, Ottawa, Mountain and Farnham Subdivisions, bridge No. 54.4, Muskoka Subdivision, Bridge No. 92.3 Boundary S.D., and Bridge 54.0 over new cut McLeod S.D.

16297—April 12—Authorizing Twp. of Roxborough to construct highway across C.P.R. near Mountain, Twp. Roxborough, Ont.

16298—April 12—Authorizing C.P.R. to construct spur into premises of Canadian Carbon Co., Ltd., Winnipeg, Man.

16299—April 12—Authorizing C.N.O. Ry. to cross public road between Cons. 1 and 2, Ottawa Front, Twp. Nepean, Ct. Carleton, Ont.

16300—April 12—Approving details of structure to be built by G.T.P. B.L. Co. authorized by Order 15088, Oct. 13, 1911.

16301—April 12—Authorizing C.P.R. to construct bridge 65.3 over Irrigation Siphon, Calgary Subdivision.

16302—April 13—Approving by-law of Midland Rly. of Canada (G.N.R.) authorizing Charles E. Dafoe, Supt. and Gen. Frt. and Pass. Agt. to prepare and issue tariffs of tolls.

16303—April 13—Authorizing C.N.O. Ry. to cross public road between Lots 10 and 11, Con. 4, Twp. of March, Ct. Carleton, Ont.

16648—April 23—Approving location of C.P.R. freight shed at Saskatoon, Sask.

16649—May 29—Authorizing Kettle Valley Ry. Co. to cross highway at mileage 10.5, northwest of Penticton, B.C.

16650—May 29—Authorizing Kettle Valley Ry. Co. to cross 6 highways in the municipality of Summerland, B.C.

16651—June 1—Authorizing C.P.R. to construct three spurs into premises of Union Stock Yards Co., Toronto, Ont.

16652—May 30—Relieving V.V. & E. Ry. (C.N.R.) from erecting and maintaining fences along certain portion of its line.

16653—May 31—Authorizing city of Hamilton to construct subway under G.T.R. near Sherman Inlet, (Birch Ave.)

16654—May 29—Authorizing G.T.P. Ry. to construct branch line into Secs. 18 and 7, Twp. 53, R. 23, W. 4 M.

16655—May 31—Authorizing C.N.O. Ry. to construct spur from point on joint section of C.P.R. spur in Parry Sound, Ont., into premises of Canada Chemical Co.'s smelter.

16656—May 31—Extending until Oct. 1st, 1012, time for installation of interlocker by C.N.O. Ry. to cross C.P.R. and G.T.R. near Ottawa, Ont. See Order 11386, Aug. 6th, 1910.

16657—May 30—16658—May 31—Authorizing Campbellford, Lake Ont. and Western Ry. to cross C.N.O. Ry. in Lot 27, Con. 2, Twp. of Pickering, Ont., and Pointe-Anne Railway Co. (Canada Cement Co.) in Lot 15, Con. 1, Twp. of Thurlow, Ontario. Interlocking plants to be installed.

16659—May 30—Approving location of Campbellford, Lake Ont. and Western Ry. (C.P.R.) from mileage 72 to 75.45, Ontario.

16660—May 27—Directing C.P.R. to file within 90 days plan showing location of junctions with C.N.R. and interlocking signalling system to govern movements over tracks of 2 Cos.

16661—May 31—Dismissing application of C.P.R. to construct its Lambton to Weston Line across certain highways in Twps. of York and Etobicoke, Ontario.

16662—May 31—Dismissing application of C.P.R. to construct Lambton to Weston Branch to connect with Toronto to Owen Sound line near Toronto, Ont.

16663—May 31—Refusing application of C.P.R. for branch line from its Toronto to London line to connect with Toronto to Owen Sound line near Toronto, Ont.

16664—May 30—Authorizing C.P.R. to take lands in civic St. Andrew's Ward, Montreal, Que., for railway purposes.

16665—May 31—Orders that crossing of C.P.R. of Dovercourt Road, Toronto, be protected by day and night watchman, one-half wages by city of Toronto and one-half by C.P.R.

16666—June 4—Authorizing G.T.P. Ry. to open for carriage of traffic its line from mileage 100 to 164 east of Prince Rupert, B.C., limited to speed of 25 miles an hour.

16667—May 31—Directing C.P.R. to install standard gates at crossing in village of Hartland, N.B., within 60 days, to be operated between 7 a.m. and 6 p.m. daily, 20 per cent. from Railway Grade Crossing Fund.

16668—June 1—Authorizing Vancouver, Westminster & Yukon Ry. Co. and C.P.R. to operate their trains over crossing at Burrard Inlet, Vancouver, B.C., without stopping.

16669-70—May 30—Approving location of Campbellford, Lake Ont. & Western Ry. (C.P.R.) from mileage 106.7 from Celn Jay to mileage 123, and authorizing it to cross by means of an overhead bridge the Thurlow Railway Co.'s tracks to Canada Cement Co.

16671—June 1—Directing G.T.R. to compensate existing landowners on either side of Ferguson Avenue, Hamilton, Ont., who were owners prior to establishment of Cannon Street Yard, or to have option of purchasing same outright, etc. Application, city of Hamilton re shunting on Ferguson Ave.

16672—June 5—Authorizing C.P.R. to open for carriage of traffic second main line double track from St. Martin's Jct. to St. Therese, distance of 7.22 miles.

16673—June 4—Authorizing G.T.P. Ry. to construct two spurs to serve Alsip Brick & Supply Co., at Edmonton, Alta.

16674—June 7—Authorizing G.T.P. Ry. to cross and divert highway at mileage 58.3, Alberta.

16675—June 7—16676—June 4—Authorizing G.T.P. B.L. Co. to cross two highways on its Biggar-Calgary Branch, and to divert road from mileage 36.4 to 36.8 on its Regina-Moose Jaw Branch.

16677—June 5—Authorizing G.T.P. Ry. to cross highway at mileage 193.5, Range 6, Cassiar Dist,, B.C.

16678—June 4—Approving location and detail plans of G.T.P. B.L. Co station at Bardo, on its Tofield-Calgary Branch.

16679—June 5—Authorizing G.T.R. to construct siding into premises of Canada Brick Co., Ltd., near Montreal, Que.

16680—June 6—Authorizing G.T.R. to reconstruct bridge 4.90 on 16th Dist., near Waterdown, Ontario.

16681—May 30—Authorizing G.T.R. to construct 2 additional tracks across Bay Street, Kingston, Ont.

16682-83—June 4—Authorizing G.T.R. to construct siding for Bronson Company, in Ottawa, Ont., and for Dominion Flour Mills Co., Ltd., Montreal, Que.

16684—June 8—Extending until 15th July, 1912, time for completion of transfer track at Minto, Man. See Order 16501, May 10, 1912.

16685—June 4—Granting extension to C.P.R. for construction of spur until 30th Nov., 1912. See Order 16289, Apr. 10, 1912.

16686—June 7—16687—June 6—Authorizing C.P.R. to construct spur for Frank H. Wiley, in Winnipeg, Man., and for Hub Roofing and Cornice Works, Co., Saskatoon, Sask.

16688—June 8—Approving location of C.P.R. station at Yahk, B.C.

16689—June 5—Authorizing C.P.R. to construct spur for National Portland Cement Co., Ltd., Twp. of Brant, Bruce County, Ont., (near Hanover, Ont.).

16690—June 8—Authorizing C.P.R. to reconstruct bridge 86.1 and 57.9 on its Havelock and London Subdivisions.

16691—May 4—Authorizing C.P.R. to construct branch line to premises of Winnipeg Supply Co., Ltd., Winnipeg, Man.

16692—June 6—Authorizing C.P.R. to reconstruct bridge No. 113.5 on its Cascade S.D., B.C. Division.

16693—June 4—Authorizing C.N.O. Ry. to cross two highways in Twp. of Ross, County of Renfrew, Ontario.

16694—June 4—16695—June 7—Authorizing Campbellford, Lake Ont. and Western Ry. (C.P.R.) to take possession of portion of C.N.O. Ry. right-of-way at mileage 79.5, in Twp. of Sydney, Ont., and approving revised location from mileage 140.63 from (Glen Tay) to mileage 147.89 in County of Durham, Ontario.

16696—June 7—Approving revised location of C.N.O. Ry. through unsurveyed territory, Dist. of Thunder Bay, mileage 142.8 to 148.4, from Port Arthur.

16697—June 4—16698—June 6—Authorizing C.N.R. to cross with its Swift Current Line 23 highways in Saskatchewan, and with its MacLeod-Calgary Branch, 24 highways in Alberta.

16699—May 31—Authorizing city of Hamilton to construct Dunsmure Road across spur of T.H. & B. Ry.

16700—June 1—16701—June 4—Authorizing city of Edmonton, Alta., to cross with its electric railway the tracks of G.T.P. Rv. at Spruce Ave., and at intersection of 21st Street, with Short and Nelson Avenues; half interlockers to be installed, etc.

16702—June 7—Directing G.N. Ry. to fence its right-of-way from Elko to International Boundary with exception of where it skirts the Kootenay River, etc. Complaint, Board of Trade, Elko, B.C.

16703—June 7—Authorizing Government of Alberta to construct highway across C.P.R. on north boundary of N.E. ¼ S. 3, T. 39, R. 27, W. 4 M.

16704—May 31—Authorizing Montreal Tramways Co. to reconstruct bridge over C.P.R. near Blue Bonnets, Que.

16705—June 5—Directing that Order 16479, May 10, 1912, be put into effect by Railway Companies not later than 15 July, 1012.

16706—June 5—Authorizing Peterborough Radial Railway Co. to cross C.P.R. and G.T.R. on Park Street, Peterborough, Ont.

16707—June 4—Amending Order 16452 of Mar. 6, 1912, to substituting words, "forty thousand pounds" for words "thirty thousand pounds," where they occur in said Order.

16708—May 31—Directing T.H. & B. Rv. to protect Walnut Street crossing by day and night watchman; gate question reserved.

16709—June 5—Recommending to the Governor-in-Council agreement between Atlantic, Quebec & Western Ry., and Quebec Oriental Railway for joint shops at New Carlisle, Que.

Volume 22 Toronto, June 27, 1912

The Canadian Engineer

An Engineering Weekly

LARGEST REINFORCED CONCRETE ARCH BRIDGE IN THE WORLD.

There was built last year in Rome a bridge over the Tiber, which possesses special interest because of the fact that the span exceeds everything hitherto attempted in reinforced concrete construction. This bridge is called Ponte del Risorgimento.

The arch proper has a span of 333 ft. (100 m.), with a 33 ft. rise, (Fig. 1).* At the crown the thickness is reduced

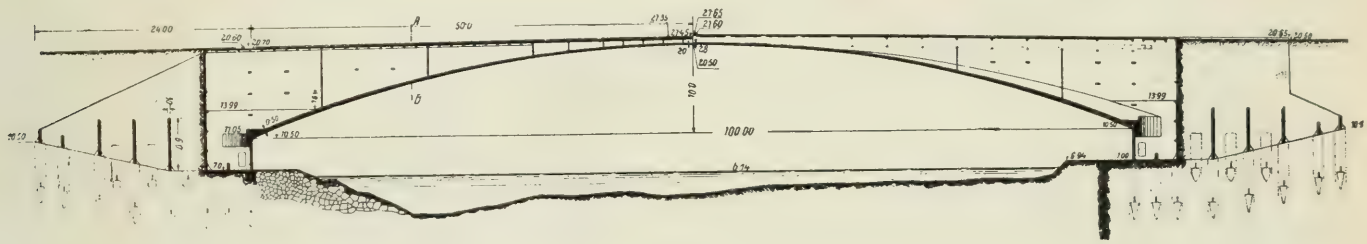

Fig. 1.

to the remarkable dimension of 8-in. (20 cm.), from this point it has been increased until it is 20-in. (50 cm.) at the springing lines. The bridge is materially strengthened by 8-in. thick stiffening ribs, which extend its whole length, and over the abutments. These consist of the above-mentioned ribs connected by cross walls and supported by concrete columns, (Fig. 2 and 3), constructed in the following manner.

A heavy conical hammer, (Fig. 4), is raised to a certain height and is allowed to fall, so that it pierces to firm ground;

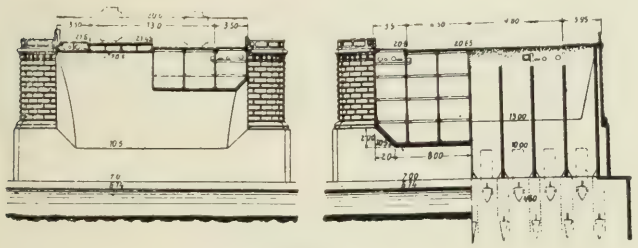

Fig. 2.

this is, of course, obtained by repeated operations, similar to pile driving. The form of this hammer ensures the surrounding earth being firm and strong, so that even when driving through loose earth, the walls of the hole will remain standing.

In cases where water percolated into the hole it was necessary to adopt some precaution to keep it dry, so as to obtain satisfactory concrete work. The manner of procedure was to introduce a quantity of clay which was compressed against the walls by the action of the rammer; in this way water was successfully kept from interfering with the concrete.

When holes had been driven down to firm ground a large quantity of gravel was introduced and rammed hard with an oval monkey for obtaining a firm footing for the concrete afterwards placed in the hole. In order to connect these

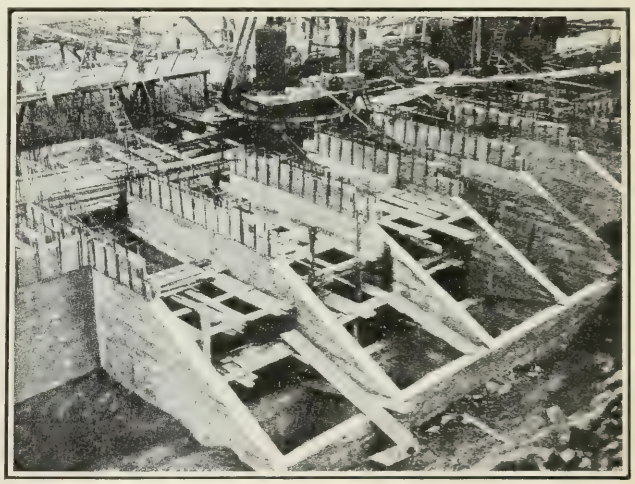

Fig. 3.—View Showing Lower Part of Abutments.

concrete piles and the superstructure a number of vertical bars were embedded in the piles.

The foundation work was done between the months of January and July, and there were frequent interruptions due to highwater in the river.

* The total width of the dredge between the triangle is 64 ft., of which the roadway is 44 ft. and the sidewalk on each side 10 ft.

At one end of the bridge a wall of rock formed a strong natural protection and prevents any damage being done by the water to the abutments; at the other end of the bridge this protection is obtained by reinforced concrete sheet piling, connected together by tongue and groove joints. These piles were sunk in position by the use of a water jet, the water being brought to the end of the piles under a head of 70 ft.

In the reinforcement of the bridge only two sizes of bars were used,* the unusual section of these bars is shown in Fig. 5, and is the design of Mr. Porchedder, (Turin), the head of the contracting firm who undertook the work.

The whole design is based on a live load of 100 lbs. per sq. ft., or 3 steam rollers weighing 33,000 lbs. each, placed in the most dangerous position.

A remarkable feature in connection with this bridge was the use of reinforced concrete scaffolding, (Fig. 6 and 7). This was of such a nature, that very little resistance was offered to the flow of the water, and at the same time great strength was obtained. The resistance power was brought out by the fact that a steamer in trying to pass under the bridge at high tide inadvertently struck two of the piles and broke them off, (Fig. 8). Notwithstanding this accident the scaffolding was still able to support the recently placed concrete.

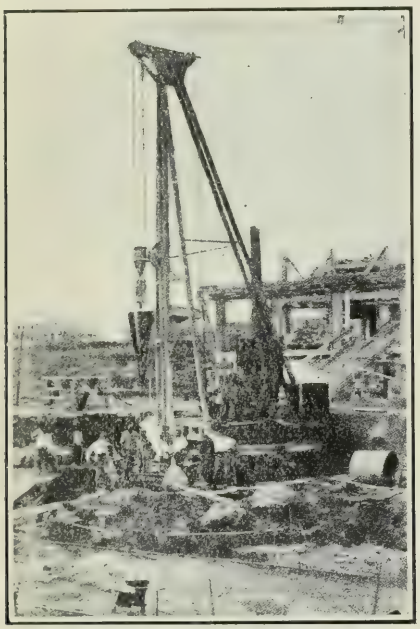

Fig. 4.

The scaffolding was built up so that each row of columns rested on 16 concrete piles placed in two rows and connected above the water-line by a beam, (Fig. 9); each group of piles constitutes a support for reinforced concrete columns, which are again framed together by a second cross beam, on which were laid wedges and wood beams for the forms.

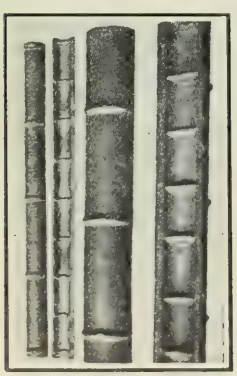

Fig. 5.

The columns and beams for this scaffolding were constructed separately, floated to the bridge and joined together by the reinforcement, filled out with cement mortar. The erection thus occupied a very short space of time.

*With sectional areas of .175 and .61 sq. in. respectively.

A concrete mixture of 500 lbs. of cement per cubic yard was used, and the consistency was very wet.

Fig. 6.

The contract price for the bridge was about $200,000.

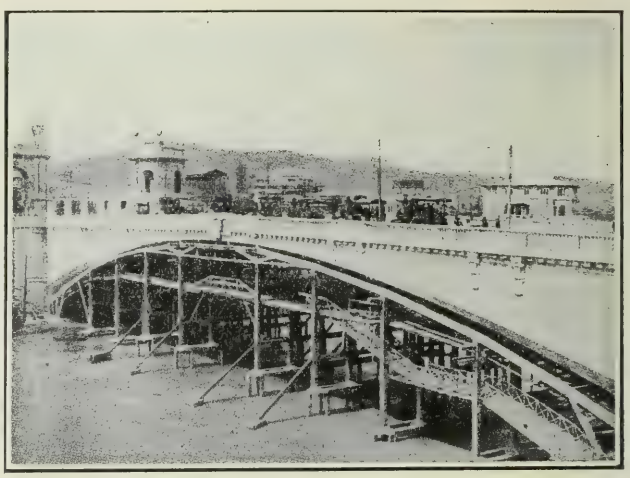

Fig. 7.—Testing Bridge by Seven Steam Rollers.

For purposes of comparison a list of the principal dimensions of some other large arch bridges is given in the table on the following page.

Fig. 8.

On page 847 of this issue of *The Canadian Engineer* will be found an article by Mr. Henry G. Tyrrell entitled "American Impressions of the Risorgimento Bridge at

Rome." This article, read in conjunction with the foregoing description will be of interest to our readers.

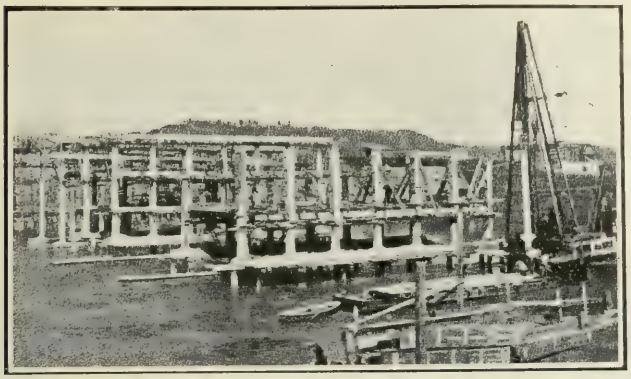

Fig. 9.

STADACONA HYDRAULIC COMPANY:

Announcement has been made at Quebec of the organization of the Stadacona Hydraulic Company, which is undertaking the development of the power at Seven Falls, back of Ste. Anne de Beaupre. The falls, which have a head of over 400 feet, will at present enable the company to obtain an initial development of 10,000 horse-power. The company is backed by a group of Montreal, Quebec and foreign capitalists, and the arrangements concluded, it is said, will result in the company being able to deliver power by the end of the present year. Among the interests identified with the company are: President, Hon. L. P. Pelletier, postmaster-general of Canada; Sir Rodolphe Forget, M.P.; Neuville Belleau, banker, Quebec; Hon. C. E. Dubord, Quebec, member of the Legislative Council of the Province of Quebec; Mr. D. O. Lesperance, banker, Quebec; Mr. Alfred Bouvier, Brussels; Mr. H. J. Bierman, Shawinigan Falls; and Mr. Andre de la Morinerie, France.

DESTRUCTION OF CEMENT MORTARS AND CONCRETE THROUGH EXPANSION AND CONTRACTION.

One of the most important of the standard tests for Portland cement is that for "Constancy of Volume"—a lulling title which carries with it the implication that our cements are actually constant in volume. It requires no very keen observer to find numerous instances where the implication has not been justified. Cracked copings and walls, sidewalks warped and split, and stucco dropping from houses, are sights which are so frequent as to force upon the observer the feeling that the phenomena must be due to some property characteristic of many if not all concretes which are exposed to the weather.

Professor A. H. White, of the University of Wisconsin, gave the results of his investigation of the subject in a paper before the American Society for Testing Materials. The paper in abstract form, as here given, is most interesting.

The change in volume of concrete due to temperature change has been determined with considerable accuracy to be for unit length 0.0000055, or 0.00055 per cent., per degree Fahrenheit. There are, however, other changes due to the chemical processes of setting and hardening which are barely mentioned in even the more important treatises, and other variations due to the wetting and drying of the concrete whose very existence is practically unknown. It is with these two latter classes of changes that this paper will deal.

The following pages show especially the effect of alternately wetting and drying bars of neat cement and sand mortar. There are also included the behavior of various bars of neat cement kept continuously in water and in air. These are included not only because more data on the subject are desirable, but because the Portland cement now being used is a different material from that tested by the European investigators, who undoubtedly worked with cements made in the old vertical kilns. The modern American cement made in rotary kilns differ from the older not only in method of manufacture but also in chemical composition, and is worthy of separate study.

Experimental Method.—The method of making and measuring the expansion bars was that of Campbell and White. The dimensions of the bars are approximately 1 by 1 by 4 ins., and they contain bevelled glass plates cast into the end to ensure a smooth surface for the micrometric measurements. The Portland cements used were all commercial samples which passed successfully the standard tests for soundness. Standard methods were used in proportioning the water and in mixing. The initial measurement was made after the bar had stood 24 hours in the damp box.

Illustrations from Actual Practice.—It may be urged that the tests were all made on small bars manufactured in the laboratory and that such large values might not be obtained in actual practice.

Bar 156 A is made from a part of the cement sidewalk on the north side of the campus of the University of Michigan. It was laid in 1890 from imported German cement by the University workmen who were paid by the day and under no temptation to slight the work or skimp cement. Most of the slabs of this walk are now warped slightly so that shallow puddles of water stand in them after rain, and even after twenty years the expansion is still occasionally causing adjacent blocks to heave and form an inverted "V." The top layer is split from the bottom in many places and it was from one of these pieces of the top coat that bar 156 A was sawed. An examination of its lower surface shows that the split was not due to faulty bonding, for the break has occurred not at the exact junction of the top coat and base,

but just below the upper surface of the base. The top coat carries with it a thin layer of the base. This bar became dampened in the sawing process and was therefore put into water and allowed to become saturated and fully expanded before the measurement recorded as the initial was made. It then contracted slowly for 14 days in the air, the total shrinkage being 0.05 per cent., and on putting it into water it expanded to practically its initial volume in 4 days. When removed from water it contracted again as before.

Another instance to which attention is called is bar 156 E, cut from a piece of cement stucco which came loose from a brick porch after only two years' service. The stucco is well mixed, has a good ring and is hard. The brand of cement used and the proportions are unknown, but it is certainly a rich mixture, probably as high as 1:1. The stucco in coming off did not split off from the brick but in almost all instances carried a thin skin of the brick adhering to it, showing that the fault did not lie in failure to bond the materials together. The behavior of a bar sawed from this stucco is shown in the curves for 156 E. It was sawed to shape without moistening, and when placed in water for 24 hours it expanded 0.07 per cent. and reached 0.08 per cent. after 4 days in water. On drying in air is slowly returned to its original volume. It is not to be wondered at that a stucco which expands practically 1 in. in 100 ft. whenever it gets thoroughly wet, should fail.

Another instance of change of volume in material which has been in use many years is afforded by the study of a section of cement sidewalk which was taken up in good condition after 20 years' service. From this was sawed a bar approximately 1 by 2 by 4 ins., consisting of the top coat 1 by ¾ by 4 ins. on a section of the bottom portion 1 by 1¼ by 4 ins. This bar (156 B) is, therefore, similar in many ways to the compound bars of neat cement and 1:3 mixture before referred to. It showed the usual expansion of both layers in water and the contraction in air which was expected. When placed in water the bottom layer expanded practically its whole amount (0.033 per cent.) in 15 minutes, while the richer top layer expanded in the same time only 0.010 per cent. At the end of 24 hours the top portion had expanded 0.028 per cent., and after 3 days had become practically constant with almost the identical expansion 0.035 per cent., which the bottom showed. This is interesting partly because of the evidence of alternate bending stress in the concrete due to the more rapid expansion of the lower layer and partly because of the ultimate agreement in expansion of the top and bottom portion. Note that this cement sidewalk was in good condition after 20 years' service. It is possible that its satisfactory condition is due to this agreement in coefficient of expansion of the two layers.

Summary of Experimental Data.—In the foregoing there have been presented data on the sadly neglected subject of expansion and contraction of hydraulic cements as they age in water and in air and as they are alternately wet and dry. It should be emphasized, however, that the number of experiments is entirely inadequate to make it proper to quote them as average results. They are to be regarded merely as illustrations of how some acceptable commercial cements have behaved. It is, however, permissible to summarize the extremes to show the range of fluctuation.

Neat cement bars hardening under water.—After 1 year, expansion 0.07 to 0.15 per cent.; 1 year to 4 years almost no change; on drying after 3 years in water, contraction 0.13 to 0.15 per cent.; on wetting again, expansion 0.13 to 0.17 per cent.

Neat cement bars hardening in air.—Contraction after 3 months, 0.14 to 0.28 per cent., after 1 year, 0.18 to 0.34 per cent., with slight increase to 4 years.

Cement-sand bars, 1:3.—Hardening under water, expansion 0.01 to 0.05 per cent., the greatest changes being in the first few weeks; hardening in air, contraction 0.06 to 0.09 per cent., most of the contraction being in the first three months; on wetting and drying, expansion 0.04 to 0.09 per cent. on wetting, and contraction within same limits on drying.

Compound bars made of one layer of neat cement on a layer of 1:3 sand expand and contract together but at different rates and to different degrees. The differential expansion varies from 0.00 to 0.15 per cent.

The one natural rock cement tested showed twice as much variation in volume as Portland cement.

These variations in volume with change of moisture content do not disappear with lapse of years, for changes of 0.05 and 0.06 per cent. have been observed in bars cut from sidewalks which have been laid 20 years.

Changes in Monolithic Cement and Concrete.—These changes noted above may seem small, but when converted into other figures their real seriousness becomes apparent. The following hypothetical illustrations are presented to show the magnitude of the possible stresses.

Imagine a wall of neat Portland cement 100 ft. long anchored at each end to absolutely immovable supports. Let it be kept under water for 3 years. At the end of that time it would, had it been free, have expanded 0.1 per cent., or 1.2 ins. Since it is supposedly not free to expand the compression will be 0.1 per cent. and the compressive stress, on an assumed modulus of elasticity of 5,000,000, will be 5,000 lbs. per sq. in. Perhaps the cement could withstand this pressure.

Imagine now that this cement wall becomes dry. It should contract 1.7 ins., but since it is not free there will be developed a tensile stress of 7,500 lbs. per sq. in., which is several times more than it can stand. The wall would have to crack.

Suppose this neat cement wall had been originally allowed to harden in the open air. After 2 years it would, if free, have contracted 0.25 per cent., but since it is anchored at the ends there will be (assuming the same modulus) a tensile stress of 12,000 lbs. per sq. in. Is it not evident why neat cement is not used in practice?

If the above wall had been built of concrete with the same volume changes as the 1:3 sand bars and as the old sidewalks whose measurements are given above, its change in length between the wet and dry states would probably have amounted to 0.05 per cent., which with a modulus of elasticity of 2,500,000 lbs. per sq. in. corresponds to a stress of 1,250 lbs. per sq. in. The concrete could withstand this in compression but not in tension. Not even our best steel will stand indefinitely repeated alternate bending stresses nearly to its elastic limit. Why should we wonder, then, if a rich cement mixture should ultimately crack when exposed to the stress resulting from a volume change of 0.05 per cent. every time it is exposed to rain or sunshine.

There is no experimental evidence which shows the changes in volume of leaner concrete. It is evident that the properties of the sand and rock become of increasing importance as their percentage increases. The tests by Schumann on volume changes in building stones, quoted at the commencement of this paper, show small values for limestones but variable values for sandstones, the upper figures being almost as high as those quoted for neat cement. Whatever the values might be for crushed stone as used in concrete, it is hardly conceivable that gravels and sands which have withstood the action of the weather for centuries without disintegration can change their volume much when wet and dried. It seems probable that in gravel concrete

the volume changes decrease as the proportion of cement decreases, until a certain lower limit is reached where the change in volume is purely a capillary phenomenon.

If this line of reasoning is correct those concrete structures should be most stable when exposed to the weather in which there is just sufficient cement to give strength but not enough to cause excessive volume changes. Practical experience apparently confirmes this view.

Stucco.—There are many instances where stucco has remained perfect even when exposed to the weather for half a century. There are probably more instances, especially in recent years, where stucco has failed miserably in five years. The excellence of old stucco is sometimes laid to the natural rock cement with which most of it was made. It is not safe to deny this on the evidence of a single experiment, yet attention may be drawn again to the one natural rock cement which has been tested in our laboratory, whose volume changes were in every way much greater than those of Portland cement.

Is it not more probable that the old stucco has survived because of its lower proportion of cement? When it was simply a question of providing a rough brick or stone wall, entirely durable in itself, with a smooth surface, and when in addition hydraulic cement was expensive, it was natural to use a mortar containing just enough cement to adhere to the wall. With the introduction of metal lath as the support for stucco, and the necessity of protecting the metal from corrosion, coincident with the drop in price of Portland cement came the use of richer stuccos.

The step was apparently an unfortunate one, for a volume change of 1 in. in 100 ft. as shown by the stucco 156 E as it changes from the wet to the dry state cannot but cause cracks. They may be only hair cracks, for with a crack every 12 ins. each crack need only be 0.01 in. wide to take up the whole change in volume. The elastic metal lath will probably yield without mechanical injury, but the protection against corrosion which the stucco is supposed to afford disappears with the first hair crack, and unless the lath has been better protected, by galvanizing or painting, than most sorts are by the manufacturers, its days are numbered. It would have been better to have used a leaner stucco and kept it free from cracks.

A stucco rich in cement may also split off in time from brick where a lean stucco would have remained good. The change in volume of brick when wet and dry is, according to Schumann, less than 0.02 per cent. If the change in the stucco is 0.08 per cent. there is opportunity for a stress corresponding to a volume change of 0.06 per cent. which might be 1,500 lbs. per sq. in. The fact that the stucco has not split off in one or two years does not mean that it may not split off in five or ten years.

Interior Floors.—The question of reinforced concrete is discussed in a later paragraph. Here only the changes in the concrete itself will be considered. The usual practice will be assumed in which there is a base of rather lean concrete covered with a wearing coat of mortar sometimes as rich as 1:1.

The first case assumed will be that of a cellar floor where the base is tamped down and the top coat at once put on, giving the best conditions for bonding. The whole mass gradually dries out and shrinks, but the top coat, because of its high content of cement, shrinks more. The top coat will tend to separate from the base, but since a cellar is always relatively damp there will probably be little trouble.

The situation is not so favorable when a top coat is to be laid on an upper floor of a concrete building. The main portion of the floor has been poured for possible three months and has already completed most of its shrinkage. Its surface is also probably dirty so that the freshly poured mortar will not readily unite with it. Both of these circumstances are unfavorable. The fact that the main portion of the floor has already dried out and shrunk causes an even greater differential shrinkage of the top coat. The advice is usually given to wet the floor thoroughly before pouring the top coat. It would be better to keep it wet for 24 hours beforehand in order to give it an opportunity to expand to somewhere near its initial volume.

It is not surprising if, under these circumstances, the top splits off the base, shrinkage cracks appear, and the individual slabs curl up somewhat at the edges in the effort to relieve the shrinkage strains. In case electric conduits, etc., are bedded in the top coat their course will be indicated by shrinkage cracks following the lines of weakness which they cause. Since these floors remain continually dry, conditions will become constant after a few months, and there will be little further change.

Sidewalks and Pavements.—The chief factor which influences the behavior of sidewalks and pavements is the weather. The influence of temperature is well known and will not be dwelt upon. A sidewalk usually consists of a base of rather lean concrete covered with a wearing coat of cement mortar which may be as rich as 1:1, and is not usually poorer than 1:2. The walk is cut into blocks and is sometimes provided with expansion joints.

As the walk dries out the top coat shrinks more than the bottom, as shown in the experimental study of compound bars. The effect can often be seen in sidewalks where the contraction has dished the entire slab so that shallow puddles of water stand in them after a rain. When the walk is wet by the rain the top expands more than the base. The alternate bending stresses thus developed all too often show themselves after a few years when the top coat splits off the base.

The necessity of expansion joints is now well recognized, although they are put in principally to take care of expansion due to changes of temperature. The experiments presented in this paper on both neat and sand briquettes indicate that the expansion of cements kept wet ceases at the end of a year, and that the total expansion does not amount to over 0.1 per cent. This would require a ¼-in. expansion joint every 20 ft. In addition there must be the joints to care for the expansion due to summer heat, which for a rise of 100° Fahr. is 0.05 per cent., about half of what may be expected from moisture. To take care of the volume changes from both these causes a ¼-in. expansion joint every 10 ft. should be adequate, although it does not include much margin of safety. In hot weather after a long rain these joints would be almost closed. In dry or colder weather they would be open.

According to the experimental figures any evils due to expansion should make themselves evident during the first two years, but practice does not always bear out this assumption. Reference was made at the commencement of this article to the cement walk laid around the campus of the University of Michigan twenty years ago, which is still showing expansion and giving mute evidence of the pressure generated by occasionally thrusting up two adjacent slabs in an inverted "V". This is not a phenomenon due to summer heat for it occurs usually in the spring. What is the cause which is still making this walk expand after twenty years?

An explanation may be suggested, although it is not possible to prove it completely. It is well known that the glass of thermometers expands when heated and contracts when cooled, but not to its original length except after a long lapse of time. Thermometers which are used frequently at

high temperatures keep growing longer. If they are laid away for a long period of time they shorten again and may even become shorter than when first calibrated. Metals behave similarly, so that it is not possible to utilize their expansion for making pyrometers which will not need frequent recalibration. The warping of the grate bars of fireboxes due to expansion is another illustration. It would be natural to expect analogy that concrete would tend to a permanent expansion when it is kept wet longer and oftener than it is dry, and that it would tend to become shorter under the opposite conditions. The experiments of this paper in general confirm this theory. Of the five bars of neat cement which had been kept under water for three years and were then dried out and re-immersed, all but one were longer after the re-immersion than they had been, and the one exception is apparently susceptible of explanation.

A more striking illustration is afforded by the two neat bars 146 A III. and A IV. These bars were made on the same day from identical materials, but after the initial measurement A III. was left in the air and A IV. placed in water. They were then alternated between air and water, at first at the end of each week and afterwards at longer intervals. There is, however, a definite difference in the treatment of the two, for with A III. each cycle has consisted of a period in air of two or three months followed by an immersion in water of usually a week. It has, therefore, been dry most of its life and its mean length since the end of the first month has been steadily diminishing. The companion bar A IV. was subjected to the opposite treatment in that its long periods were in water and its short periods in air. Its mean length and also its length when wet has been steadily increasing for the 18 months of its existence, although the rate of increase since the ninth month has been slow. At its last measurement it was slightly longer than another bar of the same cement which had been kept constantly in water, but it will require a longer time to decide whether the increase is material.

This theory of the continued expansion of cement walks in a rather damp climate, such as that of Michigan, is the only one which seems to adequately explain the compression ridges still occasionally developing in the twenty-year-old walk on the campus of the University of Michigan which has been referred to before. If the theory is correct it would indicate that there would be more trouble with cement sidewalks and pavements in wet countries than in those which are reasonably dry, and that there is need of much wider expansion joints in damp climates.

Reinforced Concrete.—It is evident from the data presented here that concrete undergoes a notable shrinkage as it drys. If a concrete beam is formed rigidly fixed at both ends, as is practically the case in skeleton concrete construction, it is evident that it must, on hardening, be under an initial tensile stress due to contraction. Conditions will not be changed by the presence of steel reinforcement provided the ends are absolutely rigid. If, however, the ends of the beam yield at all, and the concrete adheres to the steel, the strains will be adjusted between the two. The steel will be in compression and the concrete in tension, but to a lesser extent. In the review of the literature at the commencement of this paper attention was directed to the experimental work of Considere and to the experiments of Emerson, who found that even with mixtures as lean as those used in practice, compressive stresses of 2,500 lbs. per sq. in. might be developed in the steel through the volume changes in the concrete of bars only 3 ft. long and not anchored at either end. The paucity of information on this subject should be emphasized. There is every probability that there are important stresses in all reinforced concrete work due to volume changes in the concrete of which the designers have had no knowledge. These stresses may have been to blame for some of the collapses which have occurred in reinforced work, and the small number of such collapses may be more a tribute to the value of the factor of safety than to scientific knowledge.

It is encouraging to note, however, that in buildings, where the beams remain dry, most of the contraction will have taken place at the end of the first three months and that from that time on the volume changes will be slight. Concrete floor beams are treacherous during the first few weeks, not only because the concrete itself is new and weak, but because of the tensile stresses developed.

There is danger that a rather slight load on a green beam may cause cracking if not total failure, for it is entirely possible that the whole of the concrete is in tension and its tensile strength at that stage is very small. Several weeks should be allowed to elapse, even in warm weather, before the forms are taken off and the supports removed. Fortunately these tensile stresses seem to practically reach their maximum in three months, while the concrete gains in strength for a much longer period, so that if a concrete building is successfully completed there does not seem to be a probability of future failure due to changes within the concrete.

Causes of Change of Volume.—There is no experimental work to account for these volume changes. Their progressive nature as the cement hardens in water or air makes it evident that they are connected with the chemical processes of hardening. Since the hardening of cement is recognized as being essentially a process of colloid formation and change, it may seem not unreasonable to hold that the changes are connected with the volume of the colloid water. The nature of the volume changes as cement passes from the dry to the wet state is in harmony with this view. It is probable that the volume changes are also due in part to purely capillary phenomena, for sandstones and other building stones expand when wet and contract when dry. The amount of the expansion and contraction of concrete decreases as less cement is used, so that it appears that the changes are more a function of the cement than of the mineral aggregate.

The subject has not been sufficiently studied to show how far such factors in the manufacture of cement as chemical composition, temperature of burning, fineness of grinding, and rate of setting, influence the result; nor how far conditions surrounding its use, such as amount of water, temperature of air, etc., affect it. Until the influence of these factors has been determined it will not be possible to make intelligent progress towards lessening the volume changes and increasing the reliability of structures containing Portland cement. The subject is of such importance as to merit most thorough investigation from both the chemical and mechanical side on a larger scale than has yet been attempted.

Conclusions.—Concrete hardening in a moist place and remaining continually moist throughout its life expands slightly, but the compressive stress developed in the concrete is probably not large enough to be injurious.

Concrete hardening in air and remaining continually dry contracts. The contraction is roughly twice as much as the expansion of concrete continually damp. This greater stress is harmful not only on account of its magnitude but because it puts the concrete in tension, where it is weakest. It introduces an error of unknown magnitude into the calculations for all reinforced beams. It is responsible for the cracks in the top coat of interior cement floors. Fortunately most of the bad effects become evident within three months.

Cement sidewalks, pavements, and stuccos exposed to the weather contract when dry and expand when wet. The

richer the mixture is in cement, the greater is the volume change, so that there is a differential expansion between the top coat and base of sidewalks which is often sufficient to split the two apart. So also rich stucco may be split from brick. In damp climate irregular expansion occurs apparently for as long as twenty years. Its harmful effects may not appear for many years. Large expansion joints are necessary in sidewalks and pavements.

Rich stuccos will inevitably crack through expansion and contraction, and may be ruined. The few experiments made indicate that integral waterproofing compounds do not prevent or lessen the changes in volume. The only safety seems to lie in the use of lean mixtures whose volume change is slight. A stucco coat is inadequate as a protection for metal lath. If it is rich enough to keep water out it will crack. If it is lean enough to avoid the cracks water will go through it freely. In a dry climate the tendency is for sidewalks and stuccos to shrink more than they expand. Under these circumstances they will be much more durable, because of the slower corrosion stucco may be permissible as a protection for wire lath

AMERICAN IMPRESSIONS OF THE RISORGIMENTO BRIDGE AT ROME.

By Henry Grattan Tyrrell.*

Since the publication of my treatise on "Concrete Bridges and Culverts" in 1909, rapid progress has been made in the direction therein indicated, in the design of concrete bridges. Instead of the heavy masonry bridge with many piers, solid arch slabs and earth filling, practice has swung to the other extreme where reinforced concrete is used with individual members and outlines similar to those in steel, the framing in some cases being extremely light, as in the recent Mizenhead bridge in Ireland.

It is interesting to note that the world's record for a masonry arch, after the lapse of more than 2,000 years, is again at Rome. Pons Aemilius, (Fig. 1) which was completed 142, B.C., after undergoing numerous repairs, continued in use until 1890, when most of it was removed to make room for a new steel bridge with its deck supported on horizontal girders, the new structure now being known as Palatine bridge. Many of the old Roman bridges which were known as stone arches, were really only faced with stone, the body of the arch and piers in many cases being concrete; and the same system of construction was carried out in Roman buildings and other works. It is, indeed, known that concrete was much used many years before the Christian era, not only in Rome, but in Greece, Etruria, Assyria, India, and China, and it is also found in the Pyramids, the Walls of Babylon, as well as in the Great Wall of China. Occasional evidences of the use of concrete in bridge construction after the fall of Rome still remain, as in the bridge at Amalfi, Italy, built by the Moors in the sixth century.

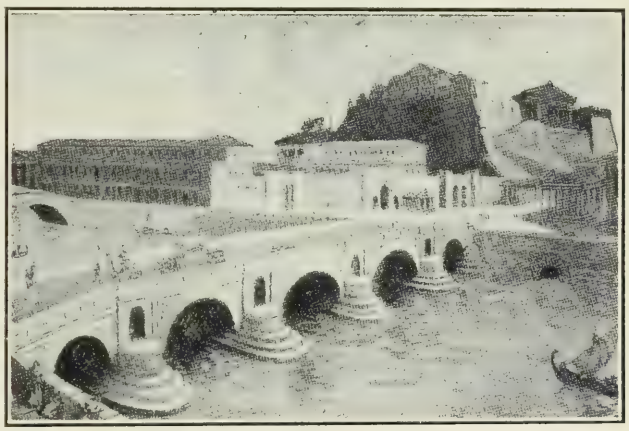

Fig. 1.—Pons Aemilius.

The Risorgimento bridge (Fig. 2) over the Tiber at Rome, with its clear span of 328 feet (100 meters) is in many ways a striking contrast to those adjoining it, and it is probable that if the old Roman engineer, Lucius Fabricius, who built bridges over the Tiber in the early part of the first century, could examine the latest one, he would likely view it with suspicion and disapproval.

The new bridge has a deck 65½ feet wide at a height of 47 feet above low water, and it crosses the Tiber with a single span. Compared with other concrete bridges, the next longest one Fig. 3) is at Auckland, New Zealand, with a span of 320 feet, and its deck 147 feet above water. In America the longest concrete spans are those at Larimer Avenue Pittsburg; Monroe Street, Spokane, and Detroit Avenue, Cleveland, with spans of 312 feet, 281 feet and 280 feet respectively. In Continental Europe the next longest concrete arch is that at Stein, Switzerland, over the Sitter River, with a length of 259 feet, (Fig. 4) though the stone arch at Plauen, Germany, has a span of 296 feet. In Great Britain, the longest concrete spans are those over the Nore River at Kilkenny, with a single opening of 140 feet, and a very flat rise, completed in November, 1910; and the slender foot bridge at Mizen Head, crossing the narrow channel to an island at the southwest extremity of Ireland, the length of span being 172 feet, and the deck 150 feet above water.

The most interesting features of the Risorgimento bridge are: (1) foundations, (2) flat rise, (3) hollow spandrels, (4) uncertain action, (5) surface treatment, (6) falsework.

(1) Foundations.—The chief requisite of an arch should certainly be an unyielding foundation. It has, in fact, become almost an axiom of design, that arches, especially those of small rise, are suitable only when such a foundation is obtainable, as at the crossings of the Niagara and Zambesi Rivers where rock cliffs rise on one side. Where arches are used on foundations other than rock, semi-circular ones, or forms nearly approaching to them are the best, and as the proportion of rise to span diminishes, the arch with its heavy lateral thrust becomes less desirable. The bed of the Tiber River, at the site of the new bridge, is composed of sand and clay underlaid to unknown depth with soft mud, necessitating pile foundations, covered with reinforced concrete grillage. This condition of subsoil would in itself, in most cases, lead to the use of shorter arch spans with greater relative rise, or to a girder bridge with only vertical reaction. Instead of heavy and massive abutments to resist the lateral thrust of so flat an arch, we find in the Risorgimento bridge, cellular construction with comparatively thin face walls backed up by seven 12-inch vertical walls, one of which is in line with each of the seven ribs on the bridge. There

* Consulting Engineer, Evanston, Ill.

is no doubt that the builders of this bridge long experienced, long experienced in such work, and particularly with the "Hennebique" construction, were entirely competent to install these foundations which were on the "Compressol" system, and yet there is little question but that limited time and appropriation is responsible to some extent for the lack of more substantial abutments, such as used in many of the other "Hennebique" bridges.

Fig. 2.—Risorgimento Bridge, Rome.

(2) Flat Arch.—Arches with small rise are generally not a desirable form, for they not only have excessive lateral thrust, but they plainly display their weakness in this respect. The beautiful Alexander III. bridge in Paris, which is a model in almost every way, is lacking in this one particular, for it fails to impress the beholder with its strength and security. Its span of 353 feet is only a little more than the latest one over the Tiber. Since other bridges at Rome have one or more river piers, it would seem that at least two piers at this site would have been permissible and would have greatly decreased the horizontal pressure on the abutments, at the same time making arches with a greater relative rise approaching the proportion of the beautiful Trinity bridge at Florence, which for more than 300 years has been accepted as ideal. A rise of about one-quarter of the span gives a very pleasing proportion when it can be obtained, an excellent illustration being that designed by Alexander Nimmo at Limerick, known as the Wellesley bridge. The desire among engineers and designers for making bridges of record proportions is well known, and while this motive may not have been an influencing one on the Risorgimento, three spans would certainly have made a much better appearance.

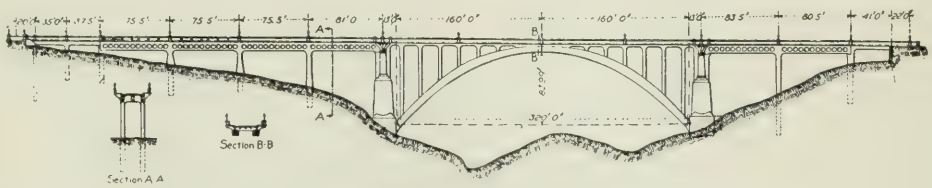

Fig. 3.—Crafton Bridge, Auckland.

(3) Hollow Spandrels.—The cellular type with hollow spandrels, which may be quite effective in the present case, is a violation of truthful construction, the general principle being that structures should, as nearly as possible, exhibit their real action and condition, and should appear to be just what they are. Concealment or deception should be avoided, and wherever consistent with construction, the general type and arrangement of parts should be evident. The accepted form in America for ribbed arches and open spandrel construction is to support the deck either on a series of spandrel columns, as in the Meadow Street bridge (Fig. 5.) in Pittsburg, or on longitudinal walls, as at Sandy Hill, over the Hudson (Fig. 6). For slab arches, the almost universal rule now is to use open spandrels with transverse arcades of colonnades. Lightness can as well be secured in these latter forms as in the more obscure and uncertain cellular type that was used in the bridge under discussion. The small thickness of the arch ring, varying from only 8 inches at the centre to 20 inches at the springs, contrasts greatly with the crown thickness of 48 inches and 72 inches on the Stein-Tuefen and Spokane bridges.

In the year 1896 Mr. Edwin Thacher made designs for two reinforced concrete bridges with hollow spandrels, enclosed on the face with curtain walls, one of the designs having a length of 150 feet. (Fig. 7). This resembles in some respects the Risorgimento bridge, and is one of the very few of this kind appearing in America. Unlike the Tiber River bridge, the American design showed only two longitudinal face walls, and those two were provided with expansion joints, making the stress conditions definite.

(4) Uncertain Stress Conditions.—Certainty of action and definite stress conditions are well known principles of bridge design. In the new Tiber River bridge with curved arch slab without hinges, rigidly connected to seven vertical ribs, it would seem that the stress condition was indefinite and the amount of thrust taken by the vertical ribs indeterminate. It is customary now, where a slab arch is used, to omit the vertical rib, or, if vertical ribs are used, to omit the slab. But the Tiber River bridge is a combination, and from the drawings which are shown in the reports of the "Ponts et Chasees" its action in this respect is indefinite. It is the practice in some bridges in America, notably those at Paterson and Clifton over the Passaic River, to make the arches continuous over the piers and anchor them securely back into the abutments, for the purpose of developing cantilever action. One of the first and perhaps most interesting experiments in this direction was that made by Brunel in 1836, when he erected a half cantilever arch of brick and cement at Rotherhithe when he was chief engineer of the Thames Tunnel. Brunel used no centering, the curve of the arch being formed by face moulds or sweeps. His experimental half arch stood on a 10-foot base, the long arm being 60 feet, while the rear or cantilever end was only 30 feet. The longer end had a rise of 10 feet 6 inches, and was balanced at the shorter end by a suspended anchor of about 31 tons. The upper and lower portions of the arch were 4 to 5 feet in width, while the spandrel wall was only 18 inches thick. He used hoop iron bands one inch wide and one-sixteenth inch thick, laid horizontally on the brick courses, and the strength of his experimental cantilever was proven by the fact that it continued standing for about two years. This interesting ex-

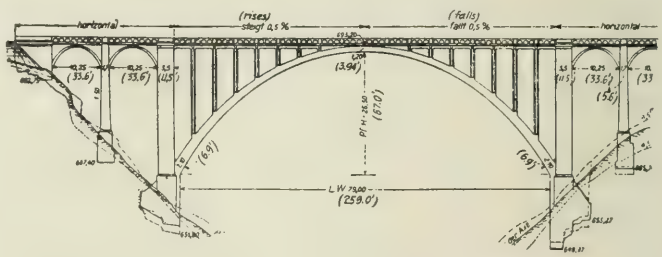

Fig. 4.—Stein-Teufen Bridge, Switzerland.

periment, which was probably the first of its kind, has been followed in more recent years by the construction of concrete cantilever bridges with members properly arranged for definite stress computation. While the Tiber River bridge was doubtless carefully designed, its stress conditions are certainly indefinite, owing to the combination of curved arch slab and vertical ribs, fastened rigidly together.

(5) Surface Treatment.—The surface treatment of the new bridge at Rome, with a fine flat face on the centre portion, resembling cut stone, and moulded blocks on the abutments, is excellent, being similar to that of the Sandy Hill bridge over the Hudson River, the Connecticut Avenue bridge at Washington, and the Chatellerault bridge over the Vienne (Fig. 8) built by M. Hennebique, 1899. In connection with surface treatment, it is interesting to note the efforts made in this direction since concrete bridges were first introduced. The Romans made extensive use of concrete in the body of their piers and arches, the surface being faced with travertine, their constructive methods being very plainly visible on the portion of old Ponte Rotto (Fig. 9) which still remains. The same system of construction was

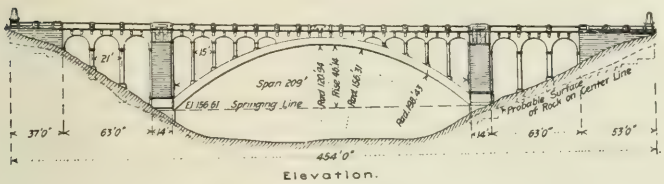

Fig. 5.—Meadow Street Bridge, Pittsburg.

extensively used on public works during the latter half of the eighteenth and the first part of the nineteenth centuries, but it was not until 1840 that a bridge was made almost wholly of concrete at Grisoles in France. It was the work of the eminent French engineer, M. Le Brun, who erected a span of 39 feet 4 inches over a branch canal of the Garonne. The only place where material other than concrete was used was in the exposed end of the arch ring, which was faced with brick, and the four vertical abutment edges below the springs, which were faced with stone. All other exposed surfaces, including the soffit and spandrels, were of concrete. Ten years after the completion of this little bridge,

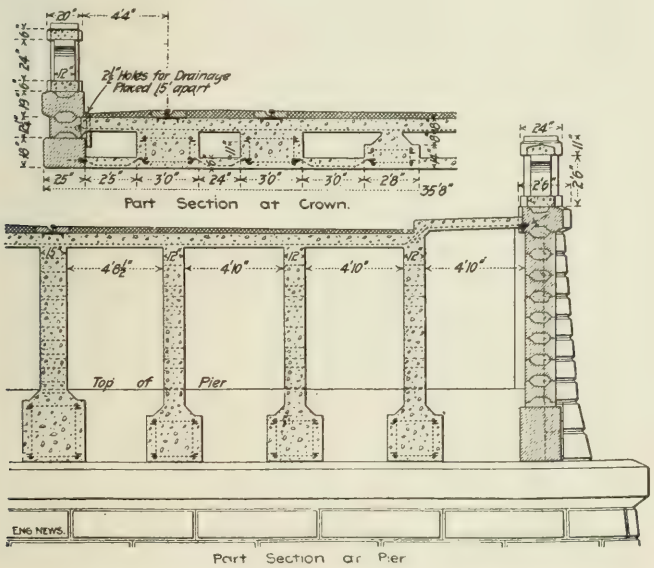

Fig. 6.—Sandy Hill Bridge, over the Hudson.

the building of the Grand Maitre Aqueduct in France was begun, the construction of which continued for fifteen years. The long series of arches, carrying the aqueduct was made wholly of concrete, the magnitude of the undertaking being hardly excelled by any later works. The surface finish on this aqueduct, however, was not satisfactory, for when concrete arches were again used in France about 1855, on many fine bridges, some of which are masterpieces of constructive art, they were faced with stone. These bridges include: Ponts au Diable, Notre Dame, Austerlitz, Arcole, Petit, Napoleon, Invalides, Alma. Experimental treatment of arch faces was again tried in 1868 when a 75-foot concrete span was erected near Gloucester Road station over the Metropolitan Extension Railway, London, the arch face being lined to represent ashlar. It was found that while bridges with concrete faces were aesthetic failures, they could be quickly built at small cost, and for several years following 1873 they were generally used by the Irish engineer Nathaniel Jackson in spans of 18 to 45 feet for highway crossings in the rural districts of Ireland.

The design of the Risorgimento bridge is lacking aesthetically, in that some prominent feature, such as pylons, statuary, or even lamp clusters, should appear above the deck over the springs, thus marking the limits of the arch and separating it from the abutments, but the absence of such features may be due to insufficient money appropriation.

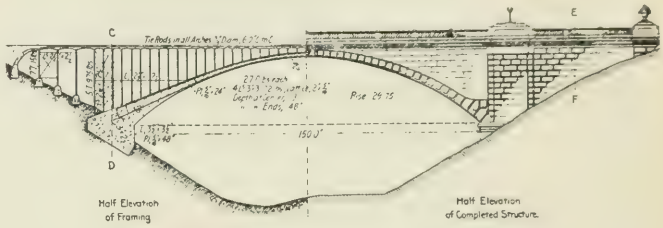

Fig. 7.—Proposed Bridge for Pittsburg.

(6) False Work.—The use of reinforced concrete false work in the Tiber bridge is interesting and unusual, and is reported to have successfully resisted the rapid autumn rise of twenty-four feet, and the additional impact of a drifting steamboat. The Tiber River is notable for its floods, having experienced no less than thirty disastrous ones since the building of the earliest bridges there. In recent times, an expedient has been used in some cases where maximum flood conditions were uncertain, in which the bridge has been designed and proportioned to resist water pressure when submerged, instances being those at Maryborough, Australia, and Paterson, New Jersey. The arrangement requires heavier construction, but permits the deck to be placed at a somewhat lower level, thereby eliminating expensive approach grades. As previously stated, the bridges over the Passaic River at Paterson have reinforcement continuous over the piers, which extends to the abutments for anchorage. The balustrades are made to be easily removed in times of flood.

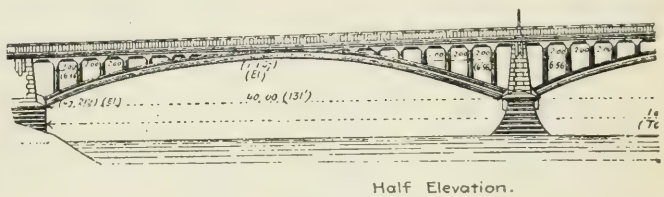

Fig. 8.—Chatellerault Bridge.

In reviewing the bridge as a whole, it is seen that the construction was carried out by representatives of the Hennebique Company, one of the most extensive builders of concrete structures in Europe. Ten years ago, their bridges were being built at the rate of one hundred per year, a record which can hardly be excelled elsewhere. The Saint Claude bridge over the Bienne, in France, with a span of 205 feet, and the well-known Chatellerault bridge over the Vienne were erected by this company. The first of these is a cellular type with springs at different levels, and built on a slight skew, finished about two years ago. It differs

from the Risorgimento bridge by having an open archway through one of its abutments, a feature which is very evident and characteristic. Compared with the next longest concrete arch span of 320 feet, at Auckland, New Zealand, these two bridges appear to be of quite opposite types, for the Tiber River bridge is all enclosed, while the Grafton bridge at Auckland is open. The New Zealand bridge has two reinforced concrete arch ribs hinged at the springs and crown, on which the deck is supported by means of spandrel columns, the whole construction being open for inspection.

Fig. 9.—Ponte Rotto, Rome.

The cost of $7.50 per square foot of floor surface for the Tiber River bridge is about the same as those at Walnut Lane, Philadelphia (Fig. 10), and at Sixteenth Street, Washington; and is quite as high as similar ones elsewhere, those at Auckland and Cleveland costing only $5.00 per square foot. The Spokane, Cleveland, Philadelphia and Washington bridges all have double arch slabs separated by a space of 12 to 16 feet, which is bridged at the floor level by the regular floor framing. The Chatellerault bridge in France, a ribbed arch of three spans, on the Hennebique system, cost only $3.00 per square foot of road, the cost in

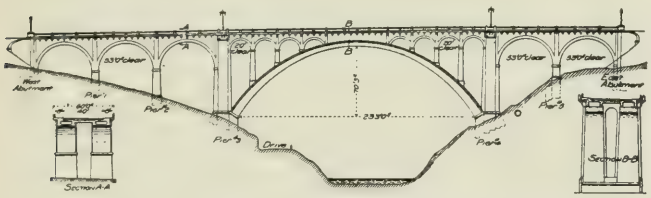

Fig. 10.—Walnut Lane Bridge, Philadelphia.

all the above cases being based on width of deck and extreme length rather than the length of opening. The Chatellerault bridge was completed in the remarkably short time of three months, while the Tiber River bridge, by the same company, occupied eighteen months, and the Grafton bridge at Auckland, about two years.

Notwithstanding its light proportions, the Risorgimento bridge withstood a remarkable test after completion, when seven steam rollers were passed over it, followed by wagons on which a large tree trunk was loaded, the whole being drawn by sixteen horses.

RAILWAY WAGES AND COST OF LIVING IN THE UNITED STATES AND EUROPE.

The Bureau of Railway Economics has completed the second of its comparative studies of railway conditions in the United States and the principal countries of Europe. This relates to the wages paid railway employees and the cost of living, and is based on the latest years for which comparative data are available.

The average daily compensation of railway employees of all classes for the year 1910 was in the United States, $2.23; in the United Kingdom, $1.05; excluding supplementary allowances negligibly affecting the average, it was in Prussia-Hesse 81 cents, and in Austria 89 cents. The lowest paid railway employee in the United States, the ordinary trackman, receives a greater compensation than many of the railway employees of France, even those of higher grades and with responsible duties. The compensation of railway employees is from two to three times as high in the United States as in Italy.

A recent report of the English Board of Trade on railway wages shows that the average weekly pay of enginemen in the United Kingdom in 1907 was $11.17; of firemen, $6.67. In the same year enginemen on American railways received an average weekly compensation of $25.80, counting six days to the week, and firemen $15.24. Recent returns make it clear that in 1912 enginemen and firemen in the United States are compensated at rates of pay for specific runs that are two, three and four times as high as the corresponding rates on representative English railways. The annual compensation of enginemen in the United States, as reported by two representative railway companies, now ranges from $1,100 in switching service to over $2,800 in passenger service, and of firemen from $700 in switching service to over $1,700 in passenger service.

For Continental Europe official returns in requisite detail are not available for a later year than 1908. The salaries and allowances of the typical engineman in Germany amounted for that year to $646.88, in Austria to $870.80; of a fireman in Germany to $424.59, in Austria to $532.03. The annual compensation of enginemen on two of the principal railways of France ranged in 1908 from $505.66 to $906.91, and of firemen from $324.24 to $595.98. In Italy enginemen received in 1908, salary and allowances included, from $581.10 to $812.70 a year; firemen, from $330.30 to $475.05 a year. In these Continental countries the maximum compensation is received after many years of service.

The average annual compensation of enginemen in the United States in 1908, on an estimated basis of 300 days' service, was $1,335; of firemen, $792. In this country the rate of compensation to these employees does not depend on length of service.

In Belgium enginemen received in 1907 from $23.16 to $38.60 a month; firemen, from $17.37 to $23.16 a month; conductors and station employees, from 46 to 96 cents a day. In the United States, in the same year, 1907, enginemen averaged, on the basis of 25 days' service, $107.50 a month; firemen, $63.50 a month; conductors, $3.69 a day; station employees, form $1.78 to $2.05 a day.

The rental of a three or four room house or flat is almost as high in Berlin, Paris or London as throughout the United States, but in England and on the Continent it generally runs from thirty dollars to ninety dollars a year less. The quantity of food and fuel estimated by the Board of Trade of England as the standard consumption of a typical workingman's family costs in the United States 17.8 per cent. more than in France or in Germany; 35.3 per cent. more than in Belgium, and 38 per cent. more than in the United Kingdom.

It is well within the truth to estimate in a broad and general way that while the cost of living of a railway employee in the United States is less than fifty per cent. higher than that of a corresponding employee in the United Kingdom or on the Continent, his compensation averages over twice as great.

DIESEL LOCOMOTIVE ENGINES.

In a lecture delivered before many of the engineering societies in the United States, Dr. Rudolf Diesel goes into the present status of the Diesel engine in Europe. One of the most interesting parts of his address is that dealing with the Diesel engine, as applied to the railroad locomotive. The following is an abstract of that section of the paper:

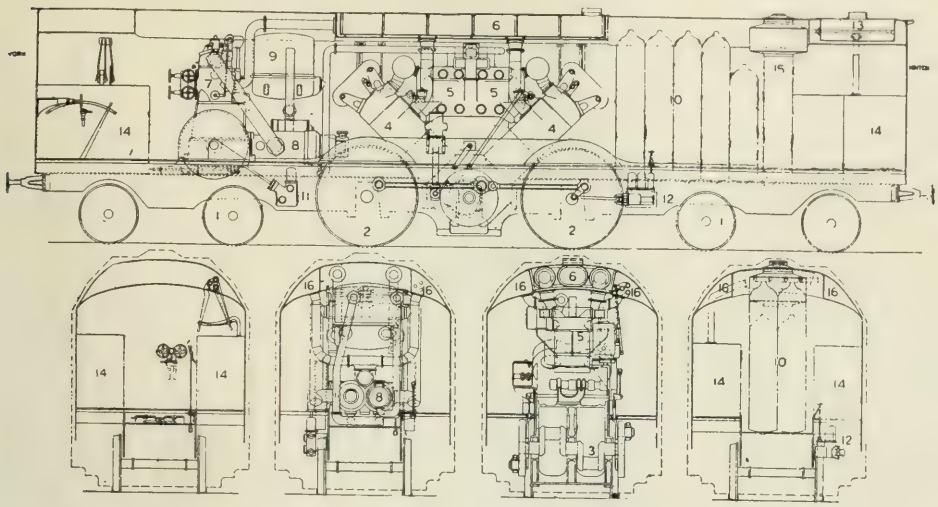

Fig. 1.—Diesel Engine Locomotive.

Of the Diesel locomotive nothing has as yet been published, and it gives the author a special pleasure to give a description of the first Diesel locomotive ever built, in this country of mighty oil wells and gigantic railways. From the early days of his invention the author was of the opinion that the special features of the Diesel engine would be of even greater importance for transport purposes than for stationary work, and, for that reason, the author devoted his time extensively to the development of the engine as motive power for transportation mediums. The author has already mentioned that he made the first small ship engine in 1902, and that since that time, the Diesel marine engine has been developed without interruption. The author further mentioned that he made the first automobile engine for trucks in the year 1909, and that he looks forward to the development of this branch within a few years. Finally, the author has to say, that he has worked for five years, together with Messrs. Sulzer Bros., at Winterthur, and Mr. Adolf Klose, of Berlin, on the construction of a Diesel locomotive, and that the first express train locomotive of 1,000 to 1,200 horse-power was finished a few weeks ago, and is now on the testing bed in the Winterthur shops. Five years is a very long time, and to explain why the work has lasted that long, the author must mention that the thermo-locomotive is the most difficult problem of construction that can be taken up in the way of modern engine building, not only on account of the difficulties in starting and manoeuvring with this special kind of motor, but also on account of the great limitations in space and weight. Compared with this, the development of the reversing marine motor has been relatively simple. Fig. 1 shows the design of this locomotive, the car of which was made in the renowned locomotive works of A. Borsig, at Berlin. It is 16.6 metres long over the buffers, and has two trucks of two axles each, 1-1, and two driving wheels, 2-2. The latter are not directly coupled with the engine, but indirectly with the blind axle (3) which is, at the same time, the crank shaft of the Diesel engine (4).

The Diesel engine is an ordinary two-stroke cycle engine, with four cylinders (4–4) coupled in pairs at an angle of 90°, and which drives the blind axle (3–3), whose cranks form an angle of 180° (see III–III). This disposition gives complete balancing of the moving masses, the first and most important condition when putting such engines on a movable platform. Between the working cylinders are placed two scavenging pumps (5) driven by levers from the connecting rod. Beyond the engine in the roof of the car is placed the silencer (6). On one side of the main engine stands an auxiliary engine (7). This latter consists of two vertical two-stroke cycle cylinders (7–7) coupled to horizontal air pumps (8–8) driven by these cylinders (see II–II). 9 indicates the cooler for the air compressed by these pumps. These air pumps serve, according to a special and patented process, to increase the power of the main engine when starting, manoeuvring and going up-hill, in such a way that auxiliary compressed air and auxiliary oil-fuel are conducted into the main cylinder, by which means the power is increased, making the engine as elastic as the steam engine. For the ordinary running of the locomotives, the main cylinders work like ordinary Diesel engines without the help of auxiliaries. To the right of the main engine is placed a battery of air bottles (10), the air from which helps the action of the auxiliary engine, and which can be refilled by the auxiliary engine at times when the latter is not used. Two pumps (11–12) provide for the water circulation in the cylinder jacket. 13 indicates an apparatus for the back-cooling of the water by evaporation, and 14, the tanks for fresh water and for fuel (see sections II–II and IV–IV). 15 is a small donkey boiler for the heating of the train.

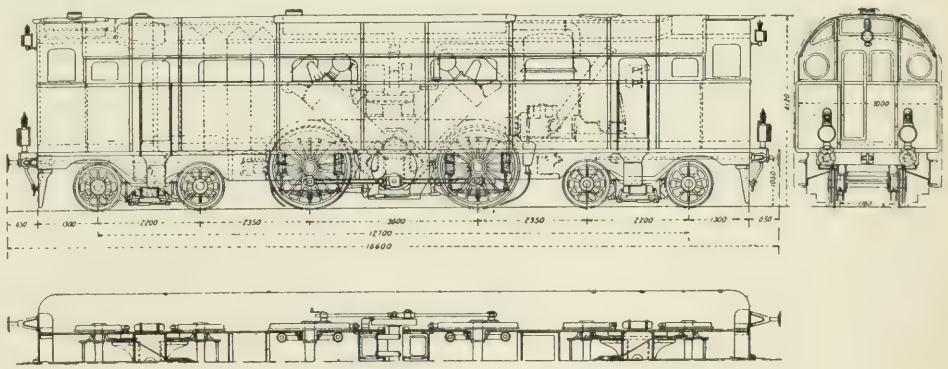

Fig. 2.

The whole plant is contained in a closed engine room which makes the locomotive look from the exterior like one of your steel cars. The canals (16) under the roof lead the fresh air to the suction pipes of the different motor and pump cylinders. The engineer can operate equally well on either side of the locomotive, as the engine is arranged for

running in both directions. He has a direct view of the track. Doors and platforms lead from the engine to the train. Total weight in service of the locomotive is 85 tons.

The author does not wish to predict whether or not this attempt at an entire revolution in the working of railways will be successful at once, or whether it must be repeated in modified form; but one thing seems certain to him: the Diesel locomotive will come, sooner or later, depending on the perseverance with which the problem will be followed.

Conclusion.—Before concluding his lecture the author desires to touch a very important question which has been put to him by the Secretary of the United States Navy, to whom he paid his first visit when coming to this country, and which has been repeated to him nearly every day since he left the pier at Hoboken: Why are we in America so far behind Europe in the development of this new prime mover, which in fact is no more new to-day?

To answer this question the author must emphatically state that the Diesel engines built in this country, after having passed the necessary manufacturing apprenticeship more than ten years ago, have been and are quite as good as the European machines. So the question is not a technical one, but merely a commercial one, or even more one of the general economical conditions of this country. The author does not know the United States sufficiently to judge these conditions on his own behalf, but he has tried to find out, in his conversations with many prominent engineers, and the following is what he could learn:

First.—Coal is much cheaper than in Europe, and, therefore, people are more wasteful with it; while the leading idea in Europe is always the economy in operating cost, the leading idea in America is economy in first cost. The word efficiency, which is the base of every contract in Europe, seems to be unknown to a vast proportion in this country. Of course, not to engineers, but to business men and to purchasers of engines.

Second.—Steam engines are much cheaper in America than in Europe, but the Diesel engine is not and will not be a cheap engine; it aims to be the best engine and must be constructed of the very highest class of material, with the best tools and by the most skilled workmen; this makes it difficult for it to compete when such ideas prevail.

Third.—Another general reason seems to be, in very many cases, the lack of capital of the prospective purchasers, and also, the higher rate of capital interest prevailing in the American money market.

Fourth.—A further reason is this: that in the last few decades the general business profits have been so big, that people did not care for the most economical methods of production and for the strictest economy in the fuel bill, as well as other expenses,—the ruling object having been to manufacture quickly and in quantities, without much regard to the cost. American industries had not, as those of Europe, to compete with the industrial countries of the world. The author has been told by American engineers that what has happened with the Diesel engine, has also exactly happened to the large gas engines, especially with blast furnace gases, and also with the steam turbine, both of which have been taken up in this country long after the development in Europe. The same has also happened with the by-products of coke ovens. Even to-day, the wasteful beehive oven is in use, while in Europe the industry of the valuable by-products earns hundreds of millions every year and has had the tendency to keep the prices of the natural liquid fuels on a lower level.

All the conditions the author has alluded to seem to be changing rapidly now; this terribly wasteful performance begins to be realized, the competition has become more keen, and a conservation of natural resources is striven for more than ever before. If this is true, the high-class engines with the highest efficiency will begin on this side of the ocean to have the same importance as abroad.

In conclusion the author expresses the hope that he has given a true and clear picture of the development of the Diesel engine in old Europe, with a few reminiscences of the pioneer work in America, and finally wishes to call to his hearers' minds the fact that nowhere in the world are the possibilities for this prime mover as great as in this country.

THE ELECTRIFICATION OF STEAM RAILWAY TERMINALS.*

By W. F. M. Goss.†

A proposition involving the complete electrification of steam railway terminals in any considerable city constitutes a problem which touches closely the comfort and welfare of the community involved. It is conceivable that through electrification the beauty and cleanliness of a city may be so affected as to stimulate greatly its prosperity and growth, and it is conceivable also that through electrification a burden of financial responsibility may be created which will place severe limitations upon its commercial and industrial development.

The city of Chicago presents at the present time an area of 194 square miles, which is cut up by 2,600 miles of railway track. The Committee of Investigation on Smoke Abatement and Electrification of Railway Terminals of the Chicago Association of Commerce, in the study of its problem under the immediate direction of Mr. Horace G. Burt, has thought it wise to add certain areas so as to include outlying transportation lines correlated with those within the city limits. The area thus defined, which is known to the committee as Zone B, embraces 235 square miles and contains about 4,000 miles of railroad track. It is estimated that 60 per cent. of this track mileage is in yards, sidings, freight and passenger terminals and industrial tracks. The remainder is in main or running tracks. In the language of Mr. Burt, "There are within the city limits 105 separate railway yards and there are many junction-points of intersecting track where an enormous volume of through and local traffic is daily interchanged and handled." A map of the city shows its railway yards to be spotted over its entire area.

If it were true that the electrification of Chicago railway terminals would at once banish smoke from the atmosphere of the city, certain important unknowns in the general problem would be eliminated, but it happens that there are in Chicago other smoke and dust-making agencies besides the 1,600 locomotives which are required to operate its railroads, and the percentage of the whole that is contributed by its locomotives is not known.

Chicago more than most cities can boast of the number and significance of her metallurgical, manufacturing and other industrial fires, not all of which are smokeless. Statistics show that within the city are 17,000 steam boilers served by nearly 10,000 stacks. Thousands upon thousands of domestic fires warm and otherwise serve the homes of this city, and these are not all smokeless. Even the motor cars

* Abstract of a paper read before the City Club of Chicago.

† Dean and Director, College of Engineering and Engineering Experiment Station, University of Illinois.

of Chicago add their quota of smoke, and the wasting of their tires their quota of dirt. It may be that the railways' proportion is, after all, not large, and that the complete abolition of this portion through electrification, or otherwise, would result in but little change in the atmospheric conditions above this city. This is one of the phases of the general problem to which the committee of the Association of Commerce, to which I have already referred, has properly directed its attention. . . . So perfectly have the plans been laid and so scientifically are they being developed that it is easily possible to foresee an accurate determination of a percentage of the total pollution which is chargeable to railway operation. . . . If it should appear as a result of this investigation that the atmospheric conditions of Chicago would be materially improved by the prohibition of the steam locomotive within the city limits, the people of Chicago will be justified in desiring most strenuously such a consummation.

There are many indications of an assumption on the part of the people that the only sure way to secure the elimination of locomotive smoke is through electrification. It appears that the validity of this assumption has not been conceded by the railways. . . . If it should appear after a thorough investigation, such as is now being made under the direction of the Association of Commerce, that the railroads are, relatively speaking, not large producers of smoke, and if it should appear that further reductions in the amount of smoke they produce are practical, the arguments to sustain a change would be materially weakened.

In the meantime, other interests in the field propose the substitution of storage battery locomotives for the existing steam locomotives. They enforce their suggestion with the argument that such a change could be made at a cost which would be comparatively small, and that while the change would add to the cost of operation, it would not involve any serious change in operating conditions. Again, the recent visit to this country or Dr. Rudolph Diesel, the originator of the Diesel engine, has stimulated in many quarters an interest in the possibility of developing a locomotive of the motor-car type which will be operated through the action of a Diesel oil engine, an internal combustion machine of high efficiency. The Diesel engine commonly uses crude oil as its fuel, but other forms of combustible liquid may be employed. The field of application of these engines has been rapidly extended in recent years. Their use in marine service has been extremely successful, and Dr. Diesel has himself developed in Germany a Diesel locomotive of a thousand horse-power. The adoption of such a locomotive for the terminal work of the railways of Chicago might result in the complete elimination of smoke and dirt, and it is believed that while it would add to the expense of existing operations, as would the storage battery locomotive, it would not greatly disturb present conditions, and the expense of the change would be small as compared with that of general electrification.

It is apparent from these statements that, if brought to the issue, the railways may prefer to adopt some form of terminal operation, which, while entirely meeting the objections to existing practice, will not involve the complete electrification of the city's railway terminals in the large sense in which that term is being used.

The general problem of electrification presents two aspects, the characteristics of which are, to my mind, wholly different. These are, first, electrification as applied to suburban passenger traffic, and second, electrification as applied to all other traffic, including, of course, switching, through freight and through passenger service. In the working out of details, these two phases may, of course, be regarded as a single problem, but the considerations which may be set forth as justifying development are not the same in both cases.

The simpler phase of the problem is that which involves the suburban passenger traffic. Every detail which enters into this problem has been threshed out by extensive construction in many parts of the country. The experience which has been gained in the electrical operation of elevated railroads in Chicago, in the electrical operation of the subways in New York and Boston, and in the extensive electric operation of interurban roads in many parts of the country, bears directly upon this aspect of the problem. Among the advantages which the public would derive from electrically operated suburban service in the city of Chicago may be counted that of reduced atmospheric pollution, of cleaner cars, of freedom from inconvenience due to the presence of smoke and cinders, and probably also that of more frequent and more rapid service. The operating railway companies would find some gain in an increased capacity of existing track facilities, in the incidental advantages which would accrue from the maintenance of a more attractive and a more effective service, and in the anticipated gain in business which the improved service would in time attract. There are no real difficulties in bringing about such a change, except such as grow out of the fact that the railroads are now equipped for steam operation. To electrify means that the existing steam operated railways which are earning dividends for their companies must practically be wiped out of existence, and new railroads built and equipped to conform with other standards of practice must be supplied. Very little of that which is now possessed, excepting the track and track structures, and possibly, though not probably, the car bodies, could be of use under the new conditions. Everything electrical, such as power plants or their capitalized equivalent, transmission and distributing lines, new cars or trucks for cars and repair shops in which the new equipment can be kept in order, must be supplied. While I am not authorized to speak for the railroads, I imagine that the difficulty is not that the cost of these things, so far as they apply to suburban service, is prohibitive, but that there is no immediate way by which existing revenues can be materially increased as the result of such a change, and because present-day directors and present-day stockholders are content with what they have. The considerations controlling the financial aspect of the matter are somewhat similar to those controlling the matter of track elevation. The progress of track elevation places heavy burdens on the railroads affected, for which the immediate return is slight, but the work once accomplished raises the character of the railway establishment to a higher standard of construction, and permits its operating service to be gradually tuned up to higher stages of efficiency. The electrification of suburban service in Chicago, while hedged about by similar difficulties, would lead to similar beneficial results, and in the absence of a plan which might insure immediate and complete electrification, it is reasonable to expect the gradual development of suburban electrification.

The complete electrification of Chicago steam railway terminals constitutes a problem of far greater proportions. As already noted, such a development would, as set forth by Mr. Burt, spread over an area of 235 or more square miles, would need to deal with approximately 4,000 miles of track and perform a service which now involves the use of 1,673 steam locomotives apportioned as follows:

To yard service	555	33 per cent.
To through passenger service	367	22 " "
To road freight-train service	364	22 " "
To suburban passenger service	208	12 " "
To freight and passenger transfer service	179	11 " "

If accomplished, it would give the public of Chicago the most marvelous railway terminal that the world has ever seen. The difficulties are not technical, but chiefly financial, and the problem of financing such an undertaking is not one which can be unceremoniously dumped on the railways, for the interests of the railways and of the community served by them are more or less identical, and neither can afford to ignore or injure the other. Probably no one knows the first cost of such an improvement, nor what its effect would be upon the earning capacity of the railways. Those who are especially qualified to speak on this subject are not talking. The Association of Commerce committee, to which I have referred, will have all the facts later, but no figures have as yet been given out.

Some conception of the manner in which expense arises can be gathered from the following very crude illustration: The first cost of a modern steam locomotive may be taken as $20,000. An electric locomotive of the same power will cost about twice as much, but the electric locomotive, unlike the steam locomotive, is not in itself a power unit. It can only be effective in doing work when there is somewhere available a power plant from which it may be supplied with current, and the cost of that portion of the power plant which is chargeable to a single electric locomotive will be a rather large percentage of the total cost of the steam locomotive. Between the electric locomotive and its power plant must be a labyrinth of electric feeders, numerous expensively equipped substations, trolley wires and substantial structures for carrying them, or, in the absence of these, a third rail and all the complicated equipment necessary to transmit the current from the plant to the electric locomotive in whatever location it may occupy on the track. Moreover, in entering upon any large scheme, such as that of complete electrification, many incidental matters arise, the cost of which, while not directly chargeable to electrification, goes to swell the total cost for the whole improvement. By the end of another year the Association of Commerce will, it is hoped, be ready with an estimate based upon an extensive research which will be entitled to the confidence of all parties in interest. The public can well afford to reserve its judgment until the committee's work is completed.

Not only must the railways consider the charges incident to the first cost of electrification, but they must be prepared for some increased cost in operation. Contrary to a commonly expressed popular conception, the actual movement of a train of cars from one point to another upon the terminal railways of Chicago can probably not be accomplished more cheaply electrically than by steam. Again, in the through train service, the electric operation of Chicago terminals would not reduce cost. Under present conditions, through trains approaching Chicago from a distant division point are brought directly into the city by their steam locomotives. The electrification of the terminals would involve the withdrawal of the steam locomotive and the attachment of an electric locomotive at a terminal located at the boundary of the electrified zone. Assuming no electrification, the additional cost of fuel and of service of the steam locomotive crew for taking the train on to its Chicago terminal, as compared with the costs entailed where the locomotive gives up its train outside of the city, is so small as to be almost negligible, while with electrification each train must bear its share of the cost of the electric service which receives it at the boundary of the zone and takes it into the city terminal; that is, electrification would make two operating divisions where one now exists, and short divisions are expensive to operate. There are many other minor difficulties and there are also minor advantages which are revealed by an analytical study of the problem, but excepting in the one matter of smoke and dirt elimination, the advantages in Chicago, where there is no operation in tunnels, are all minor advantages.

Not all of the forty railroads entering Chicago are prosperous. It would be extremely difficult for some to secure the capital necessary for the complete electrification of their Chicago terminal by the sale of securities constituting a lien upon property extending out over the country and through other insistant cities. Compulsory electrification as a measure for immediate execution would add to their present embarrassment and could hardly fail to work to the ultimate disadvantage of the business interests of Chicago.

Here it will be well to note that no great scheme involving the electrification of steam-operated lines, has ever been voluntarily entered upon by a railway company merely for the purpose of raising the character of its service from the conditions of steam operation to those which become possible through electric operation. Where electrification has been undertaken there has always been some large business purpose of interest to the railway company, in the working out of which electrification has entered more or less as a detail. For example, in New York City, the New York Central Railway was operating a long series of tunnels into its Grand Central Station. Its traffic had increased until the frequency with which trains passed kept these tunnels filled with smoke and steam. Operation became increasingly difficult, until an accident in which many lives were lost, resulting from the inability of an engineer to see the signals as he passed them, convinced the railroad officials that a change in operating conditions was necessary. In this case it was a question of giving up the Grand Central Station or of resorting to electricity. The great purpose was to preserve for the railway a valuable terminal property, and electrification proved a ready means to such an end. Similarly, the Pennsylvania Railway entered upon an extensive scheme of terminal improvement, involving a new station in the midst of Manhattan, where before no station had existed, a rail connection with the roads of Long Island which previously had constituted an isolated railway system, and the operation of tunnels under two rivers and a great city. The purpose was not primarily to electrify, but to gain a great terminal, and in the development of this purpose electricity entered as a desirable detail.

It would seem that the City of Chicago, instead of insisting upon the complete and immediate electrification of its steam railway terminals as they now exist, would do well to study carefully in conjunction with the railroads, perhaps through the instrumentality of a commission having large powers, the whole terminal problem. Such a commission could work out in a large way a development adequate to future needs. It could rearrange and simplify existing tracks, it could combine and extend existing terminal stations, it could consider every factor affecting the efficient movement of cars and the transfer of merchandise and passengers from railway terminals to destination. The working out of such plans might be expected to give not only increased facility, but also reduced cost in operation. Such a procedure, covering all of the transportation interests of Chicago, would constitute a stupendous undertaking, but nothing less can satisfy the real requirements of this great rapidly-growing modern city. The working out of any large scheme of terminal betterment, which can be justified as an economic measure, would at once provide an opening through which electrification as a detail could be, and probably would be, readily admitted.

AN ELEVATED CONCRETE TANK.

A tank constructed of reinforced concrete with a capacity of 100,000 gallons, has been erected recently for the Chicago City Railway Company Car Shops, at Seventy-Eighth Street and Dincennes Avenue, Chicago. The tank will provide fifty pounds pressure on the mains of the sprinkler system of the shop. It rests on columns 75 feet high and has a double dome bottom.

Built for auxiliary water storage to supplement the existing 1000-gal. per minute motor-driven underwriters' pump taking water from the city mains, the water in the tank will feed into the system, when the normal pressure, 90 lb. per square inch, maintained by the pump is reduced to 50 lb. per square inch. The underwriters' pump starts automatically and, to insure its constant readiness to serve, a few taps in the shops are connected to the sprinkler service mains. Ordinarily the pump starts every three hours. It is estimated the tank will supply four 1¼-in. nozzles for four hours. There are many acres of buildings, including the barns which house each night cars valued at $2,000,000. As to the choice of materials, the engineers estimated the cost of painting a steel tank with the attendant danger of fire each year while it was out of service would be about one-third of the difference between the first costs of steel and reinforced concrete tanks.

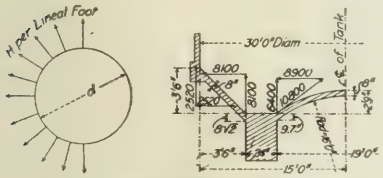

Fig. 1.—Calculation Diagrams.

In designing the tank the shell was made 8 in. thick although the engineers claim they would use 6 in. if another were built, as 4 in. is used in German practice and only this thickness is required by the calculations. Greater thickness, they hold, only weakens the structure by the additional load. Each horizontal ring is reinforced to sustain itself from bursting pressure in the usual manner. A heavier section is used at the top to contain sufficient steel to care for the domed roof. This form was used to eliminate beams, and for drainage purposes six holes opening into the tank are left at the periphery.

Two domes, as shown in the accompanying drawing, make up the bottom of the tank. The sizes are so proportioned that the horizontal thrusts over the supporting circular girder are approximately equal and opposite. The outward thrust of the inverted concentric dome at the base of the shell is cared for by an enlarged concrete section reinforced for these horizontal stresses. The methods used by the engineers in calculating the more unusual features of the tank are given below.

The roof is a section of a sphere, which is 30 ft. in diameter and 3 ft. high, and weighs approximately 58,000 lb. The shear per lineal foot at the base of the dome is $S = wd^2\pi/4 \div \pi d = wd/4$. This shear or vertical reaction is divided into two components, the horizontal tension H and the thrust T. Graphically, we obtain $H = 2.4\ S = 0.6\ wd$ and $T = 2.6\ S = 0.65\ wd$, or substituting $w = 70$ lb., $d = 30$ ft., then $S = 525$ lb., $H = 1260$ lb. and $T = 1365$ lb.

The component H produces a ring action at the base of the dome as shown in Fig. 1, and the tensile stress on the reinforcing is $Hd/2 = 18{,}900$ lb. The area of four ⅝-in. square bars is 1.33 sq. in. and the tensile stress is 18,900 ÷ 1.33 = 14,200 lb. per square inch.

The shearing stress per square inch on the concrete at the base is 525 ÷ 48 = 11 lb. The compressive stress at the base is 1365 ÷ 48 = 28.4 lb., or a factor of safety of at least 40 for the dome proper.

The vertical load per lineal foot at the base of the shell due to the weight of the shell and roof is 2520 lb. This force may be divided, as shown in Fig. 1, into two components, a horizontal tension on the ring and a thrust on the inverted dome. The angle being 45 deg., the tension per lineal foot is 2520 lb., and the thrust per lineal foot is $2520\sqrt{2}$ or 3560 lb. The stress on the ring reinforcement having an area of 2.65 sq. in. is (2520 × 30.67/2) ÷ 2.65 = 14,600 lb.

The inverted dome is subject to tension in a horizontal direction from the water pressure and is figured accordingly. The top of the dome is subject to a vertical shear of 2520 lb. per lineal foot and to a compression of 3560 lb. per lineal foot, or a shearing stress of $2520 \div 12 \times 8 \times \sqrt{2} = 18.6$ lb. and a compressive stress of 3560 lb. ÷ 12 × 8 = 37.1 lb. The weight of the inverted dome, by Guldin's rule, is $6 \times 2/3 \times 144 \times 27\pi = 50{,}000$ lb. The weight of water on inverted dome is $(30^2 - 23^2)\ \pi/4 \times 20.5 \times 62.5 = 292{,}000$ lb. The total shear at the base of the inverted dome equals the weight of the roof, the shell, the dome and the water on the dome, or a total of 586,000 lb., and per lineal feet 586,000 ÷ 23 π = 8100 lb.

This shear or vertical reaction may be divided into two components, as shown in Fig. 1, a horizontal thrust in the ring girder and a thrust on the inverted dome. The angle being 45 deg. the thrust on the dome is $8100\sqrt{2} = 11{,}450$ lb. per lineal foot. The shearing stress per square inch is $8100 \div 12 \times 8\sqrt{2} = 60$ lb. The compressive stress per square inch is 11,450 ÷ 12 × 8 = 120 lb.

The sphere has a radius of 16 ft., and the section of the sphere forming the dome a diameter of 19 ft. and a rise of 2 ft. 9 in.

The weight of the dome is approximately $19^2\pi/4 \times 1.1 \times 100 = 31{,}000$ lb. The weight of the water above it is $19^2\pi/4 \times 20 \times 62.5 = 355{,}000$ lb. and the vertical shear or reaction at the base per lineal foot is 386,000 ÷ 19 π = 6400 lb. This force may be resolved into two components, as shown in Fig. 1, a thrust on the ring girder nearly counterbalancing the thrust from the inverted dome, and a thrust of 10,800 lb. per lineal foot on the dome.

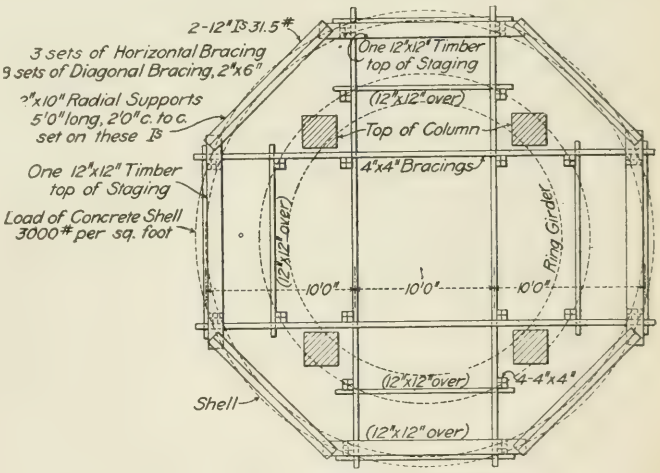

Fig. 2.—Plan of the Top Staging.

The shearing stress per square inch is 6400 ÷ 12 × 9.7 = 55 lb. The compressive stress per square inch is 10,800 ÷ 12 × 8 = 113 lb., showing also an unusually high factor of safety.

In calculating the ring girder supporting the tank structure it was assumed that the portion of the load over the columns was carried directly. The girder was then figured as a continuous beam with supports assumed 13½

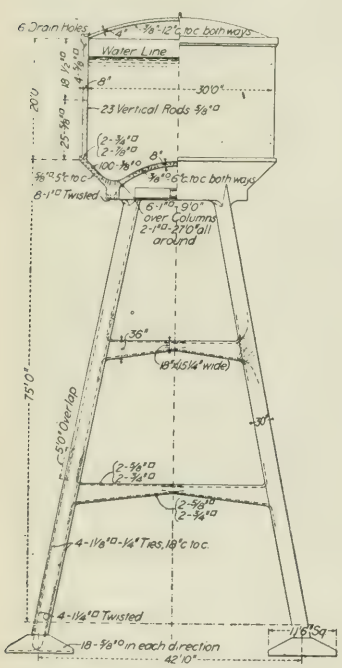
ft. apart. Bending moments of the straight line span were compounded with the torsional moment.

While stresses in the circular girder as soon as construction was completed are held to be vertical only, the weight of the green concrete in the inclined columns produced four inward thrusts on the ring. To care for these stresses concrete struts in the form of a cross connected the tops of the columns.

Assuming a force of 50 lb. per square foot on a flat surface, the total force of the wind on the round tank is 31 × 27 × 50 × ⅔ = 28,000 lb. The assumption was made that each of the two bents in one direction takes care of half this force or 14,000 lb. On account of appearances and the fact that the structure was built over an existing building, diagonal bracings were omitted, and each bent was figured as a nine times indeterminate structure.

The omission of the diagonal bracings caused bending moments in the horizontal ties and in the columns. These bending moments are greatest at the joints of ties and columns, and practically zero in the centre of the ties. The weight of the columns and ties amounts to 302,000 lb.

The direct compression from the wind at the base of the column is 14,000 × 84 ÷ 42 = 28,000 lb. The greatest load on one column is 409,000 lb. and the greatest direct stress 409,000 ÷ 900 = 454 lb. per square inch, which is increased by 390 lb. from the bending moment due to wind stresses on account of the omission of diagonal bracings, neglecting the reinforcement.



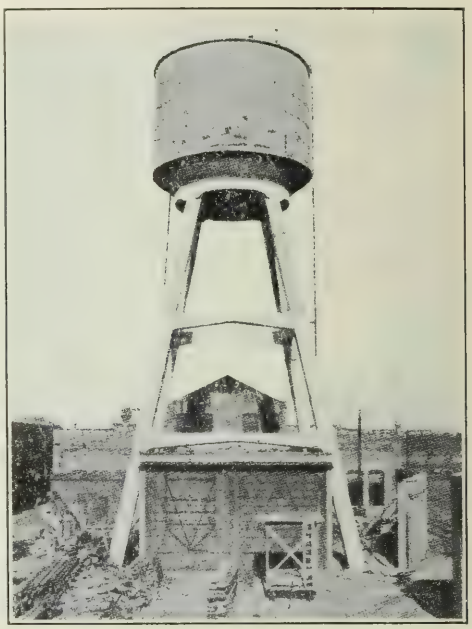
Elevation of Standards and Part Section Through Tank Showing Reinforcement.

Foundations for the legs were carried down to solid, comparatively dry, blue clay which required picking to loosen it. To the casual observer there is such a batter to the legs that sliding on the foundation would seem to be considerable, but the calculations indicate it is a negligible factor and the provision for bearing stresses, amounting to 2.9 tons per square foot, was the governing stress. No measurable settlement could be detected by leveling on the bench marks placed in the concrete legs before and after filling the tank with water.

Six-inch inlet and outlet cast-iron pipes are imbedded in two of the legs. It is believed they will be sufficiently insulated from frost by the concrete, but in addition a 2-in. steam pipe parallels the water pipe, rises 3 ft. into the tank and returns down the other column alongside the second water pipe. By the circulation of steam through this pipe it is hoped to prevent the formation of ice in the tank.

A check valve, protected by gate valves on each side ordinarily kept open, is placed on the connection to the high-pressure mains. An altitude gauge indicates the elevation of the water and a 2-in. tell-tale overflow pipe imbedded in one of the legs discharges on the ground near the outlet pipe manhole when the water is within 3 ft. of the top of the tank, at the 100,000-gal. level.

To support the form work a staging in the shape of a maltese cross was erected on top of the outer and partition brick walls of the kiln house. Six series of 8 x 16-in. timbers were laid on edge transversely over the walls and on these twenty uprights, 46 ft. long and made up of four or six 4 x 4-in. sticks, were erected. These smaller timbers were all in 18-ft. lengths as they had come from another job. Holes for the clamping boards over the butt joints were bored with electric drills and the timbers assembled and bolted up in 3 days by 3 men. While the uprights were assembled in the shop they were knocked down and subsequently erected in 18-ft. lengths by means of a gin pole and a hand winch. There were 3 sets of horizontal bracings of 4 x 4-in. timber and 8 sets of diagonal bracings of 2 x 6-in. lumber.



View Showing Elevated Concrete Tank.

Vertical supports for the shell ring form consisted of 2 x 10-in. Y.P. No. 1 planks, 4 and 5 ft. long, placed on end radially, 2 ft. apart. Fig. 2 shows the support for these radial planks. The 12-in I-beams across the corners rest on top of the 12 x 12-in. timbers laid over the uprights. Three weeks after the concrete had been placed some apprehension was felt on the part of the engineers when three of these radial supports were accidently knocked out. An examination of the remainder disclosed the fact that there was a space of 1/16 in. between their tops and the forms due, it was thought, to the shrinkage of the concrete which would cause rotation around the circular girder and also to a slight shrinkage of the staging which had been exposed all winter.

Concrete for all parts of the work except the foundation was a 1:1:2 mixture of cement, torpedo sand and 1-in. gravel. On account of the intricate framing the contractor concluded it would not be feasible to use wheelbarrows or spouts so a double elevator carrying 8 buckets of concrete on each platform was erected at one side and operated by a team of horses.

Mr. L. J. Mensch, of Chicago, designed and constructed the tank for the Chicago City Railway Company, M. H. B. Fleming, vice-president and chief engineer. The designs were checked by Mr. Hugo Schmidt, superintendent of buildings of the railway company, under whose immediate direction the work was carried out.

COAL IN CANADA.

The second volume of a series of six on an investigation of the coals of Canada with reference to their economic qualities, has just been published by the Mines Branch of the Department of Mines of Canada. This investigation of Canadian coals and lignites was begun about six years ago. At that time Dr. A. P. Low, Director of the Geological Survey, undertook a study of the fuels of the Dominion somewhat on the lines of the fuel tests which had already been commenced by the United States Geological Survey. The Government, however, had not, at Ottawa, any suitable mechanical laboratory. The Mining Department of McGill University possessed suitable equipment, and the work was, therefore, assigned to Dr. J. B. Porter, the head of the Mining Department there. Shortly after the commencement of the investigation the Dominion Deparment of Mines was created, with Dr. A. P. Low as Deputy Minister; and the investigation, together with all matters relating to economic minerals, was transferred from the Geological Survey to the Mines Branch under the directorship of Dr. Eugene Haanel. The original arrangement, however, was in all respects continued without change. It was intended originally to confine the investigation with coals and lignites of the Dominion; but owing to limited means the following points only were covered: Sampling in the field, crushing the samples and preparing them for treatment, washing and mechanical purification, coking trials, steam-boiler trials, producer and gas engine trials. chemical laboratory work and miscellaneous investigations. The technical staff engaged in the operation comprised Dr. J. B. Porter, Prof. R. J. Durley, Mr. Theo. C Dennis, Mr. Edgar Stansfield, and a large staff of trained assistants.

As was noted above, the results of the investigation will be published in six volumes, of which the second has just come to hand. A very large amount of information has been gathered for the report; much of it, however, is so highly technical as to be only of interest to specialists, hence it has been thought best to divide the report into two main sections of two and four volumes, respectively.

It was the Government's intention to compile and publish a report covering the whole field of the coals of Canada which would be of interest, not only to the engineer, but to the layman, and which would place on record all the facts possible regarding the economic value of Canadian fuels. The results, as seen in the first two published volumes, reflect great credit to the Mines Branch of the Department of Mines, who superintended the investigation, and to the Mining Department of McGill, who conducted a great portion of it.

The succeeding volumes will be awaited with interest, and, when complete, we are satisfied that this investigation will stand as an authority on the subject for many years.

AMERICAN WATERWORKS ASSOCIATION.

The American Waterworks Association has just finished its thirty-second annual convention in Louisville, Ky., and as usual the meeting has been replete with most instructive papers and interesting discussions. This year a Canadian, Mr. Alexander Milne, superintendent of the Waterworks Department of St. Cath- ..s, Ont., has been elected president, and Canadians are well represented in its membership. The

Association is a most valuable one in that, by the co-operation of its members, information concerning water-works affairs is brought to the public attention. Water supply systems are among the most important of the public service enterprises, and it is only through the cordial co-operation of the heads of waterworks departments that increased efficiency can be secured. It is surprising that the present membership of the Association is not greater when one considers the great benefits the Society are conferring. Its field of usefulness is a large one, for it deals with one of the prime requisites of our modern civilized life.

THE INSTALLATION OF ELECTRICAL MINING EQUIPMENT.

The use of electrical machinery in mines is steadily increasing. The many advantages of its use has tended towards this increase, but the requirements of safety as well as those of efficiency must be considered when installing electrical mining equipment. So important has this been considered by the United States Bureau of Mines that Mr. H. H. Clark, in the technical paper issued by the Bureau has taken up the subject quite extensively. The paper calls attention to the fact that, wherever the service conditions are indeterminate or variable, engineers are accustomed to use factors of safety in their designs, especially in those cases where the protection of human life is a consideration.

To quote from the paper: "The safe operation of electrical mining equipment is an engineering problem that invloves the element of human life, and that is influenced by conditions and events that cannot always be foreseen. The successful solution of the problem will, therefore, depend largely upon the factor of safety that is considered in the selection, installation, and maintenance of such equipment."

The paper proceeds to classify the electrical accidents that may occur in mines, and states the principal sources of danger incident to the use of electricity underground, and the paper shows that the requirements of ment in mines are compared to similar conditions above ground, and the paper shows that the requirements of mining work present certain difficulties in the way of maintaining electrical apparatus in perfect condition. The effect of roof-falls, dampness, dust, and acid water are mentioned, and the observation is made that the temporary character of underground work limits the economical investment in electrical equipment and its installation. The author does not regard the safeguarding of mine electrical equipment as a simple problem, and states that there is no general formula for its solution. It is suggested, however, that a logical step would be to remove contributory causes by placing lights and erecting guards at particularly dangerous points, and by selecting apparatus especially designed to offset the effect of dampness and dust. A concrete view of the problem is presented as follows: "The problem of safeguarding may be divested of some of its vagueness and put in concrete form by considering that if the electric current can be kept where it belongs—in the conductors designed to carry it—it cannot give shocks, set fires, or ignite dust or explosives. Electricity becomes actively dangerous only when it breaks away from its proper channels in stray currents, or as sparks and arcs."

Stress is laid upon the importance of first-class installation at the outset and frequent inspection of equipment after it is in place. The author considers that a competent electrician is needed to ensure the safest and most efficient operation of mine electrical equipment, and dwells upon the responsibilities and requirements of such a position.

EDITORIAL COMMENT.

We draw attention in this week's issue to the Index for the past six months.

* * * *

The destruction of cement mortars and concrete through expansion and contraction has an exceedingly important bearing for the engineer. The use of mortar and concrete, in engineering structures, is so extensive that any investigation having for its aim the determination of facts regarding the action of the materials under the conditions of use will be welcomed by all. In this issue of *The Canadian Engineer* will be found an abstract of a paper by Prof. A. H. White before the American Society for Testing Materials. Investigations conducted by Prof. White appear to show that cracks in concrete and mortar are due, not so much to the expansion and contraction from temperature change, but rather the volume change, due to alternate wetting and drying. The paper will repay careful reading.

* * * *

The Canadian Electrical Association convention always repays attendance, as the members well know. This year's meeting, which was held last week in Ottawa, was successful, both from the point of view of numbers in attendance and the discussion resulting from the papers read. The discussion on the paper by Dr. H. T. Barnes on "Ice Troubles in Connection with Power Plants" was particularly worthy of mention. The paper will be found in this issue of *The Canadian Engineer*. Dr. Barnes has spent many years on the study and investigation of the formation of ice in our northern waters, and it is surprising that the fundamental precautions he outlines in his paper are not universally followed by hydraulic power companies in Canada. There appears, however, to be an absolute disregard of all precaution in the design of many power plants now operating, and as a result every winter brings reports of shutdowns through ice troubles.

MUNICIPAL WORKS CONSTRUCTED BY CIVIC LABOR.

An editorial in a recent number of the Galt, Ont., Reporter deals with the above subject and states that the contractor, in as much as large civic works are concerned, has been unknown here for years—to be exact, not since 1905-6, when the $225,000 sewer contract was finished—and though many mistakes have been made, citizens prefer the present system, under which this municipality is to-day employing nearly 100 men in the construction of various civic works.

ENGINEERING WORK IN SOUTH AMERICA.

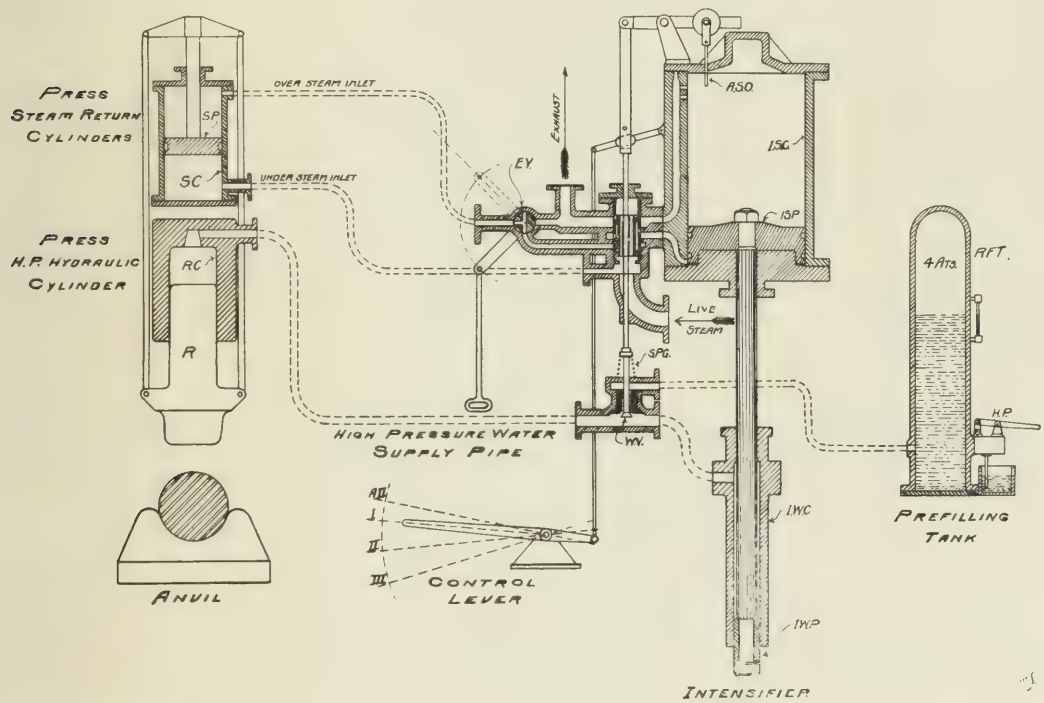
The British firm of S. Pearson and Sons, Limited, London, have received official advice from the Chilian government that the contract amounting to $13,000,000, for the construction of the new port at Valparaiso, has been awarded to them.

THE NEW STEAM-HYDRAULIC FORGING PLANT AT THE NEW GLASGOW WORKS OF THE NOVA SCOTIA STEEL AND COAL COMPANY, LIMITED.

The growth and development of its steel trade has now come to be an accepted standard for measuring a country's industrial progress. Canada's expansion in the last thirty years is strikingly shown by her steel statistics, but it is even more vividly brought home by the accomplishments of the pioneer in this line, the Nova Scotia Steel and Coal Company.

Starting as a country forge-shop with four thousand dollars' capital, this concern has expanded until its capitalization is fourteen millions, and it controls all the operations entering into the production of some six or seven hundred varieties of finished and semi-finished steel products. Particular attention, however, has always been paid to the line of work first carried on and there has never been a time when it could not claim to be the leading forge company of Canada.

By the recent installation of a complete new plant in this department, substituting steam-hydraulic presses for the hammers so long used, it has not only outstripped any Canadian company, but is in a position to challenge the product of any similar company in the world.



Diagrammatic Sketch of Steam Hydraulic Press, showing the operating cylinder and valve systems with single control lever.

Man's ingenuity has been taxed frequently to produce the massive forgings required by the engineering and mechanical advancement of the past century. Often it has seemed tnat great projects could not be carried out for lack of facilities to produce the immense steel shapes required for some particular design, but in the invention and development of the steam-hydraulic press, it would seem that these difficulties had been overcome and a principle had been discovered which would dispel all engineering difficulties of this nature.

Nasmyth's invention of the steam hammer in 1833 revolutionized the forging process of his day. During the latter part of the nineteenth century such enormous progress was made in the engineering and shipbuilding that forgings were required of a size unknown not many years previously. In turn, this resulted in a great increase in the size of forging appliances. Steam hammers were largely used at first and served their purpose well, but as the size of forgings grew, the hammer, being unable to develop a [illegible] penetration, became more and more unsatisfactory, and hydraulic-forging presses, operated by means of accumulators, were introduced. Among the first of these was one constructed at the Armstrong Works in 1850. However, they proved so slow in operation, and so expensive, that large steam hammers could still successfully compete with them. In 1860 a hammer was installed at the Krupp Works, Essen, Germany, having a 50-ton ram and a 1,000-ton anvil, while as late as 1901 a 125-ton steam-hammer was installed at the South Bethlehem Works of the Bethlehem Steel Company. Although the latter was easily the largest hammer ever constructed, it was discarded after only a few months' operation and replaced by the more efficient press.

With a hammer of this size, the force of the blow was enormous, but there were numerous difficulties in its operation. The energy developed, depending upon the weight of the falling parts, and the height through which it acted, was delivered suddenly and was exerted for but a moment. Repeated blows were therefore necessary, taking longer time than the press, and with a consequent low efficiency in steam consumption. The constant vibration made it difficult to keep a large hammer in adjustment, and wear and tear was excessive. And, lastly, the lack of control with which the blow is delivered made it a difficult operation to produce good work, and particularly to finish up heavy forging. Thus the relatively small output, and operating cost, makes hammers economically as well as technically unsuccessful in dealing with heavy forgings.

The need for a more effective and cheaper method of manufacture was met by the "steam-hydraulic" press, introduced in the late eighties, in which are united the advantages of the steam hammer, combined with those of the hydraulic-press. In this apparatus, steam cylinders lift the striking piece, or tup, which thus moves with the speed and force of a steam hammer; while constant hydraulic pressure may be supplied at any stage of the stroke by a large water-cylinder. This high pressure water is intensified in and flows from a separate apparatus called an intensifier. Thus the method of operation can be varied widely to meet different conditions. In the most modern type, in which the Scotia Company's presses are the last word, this feature enables much larger, as well as a greater range of work being performed with an efficiency impossible to any other apparatus.

The new Scotia plant consists of two presses complete with all manipulating devices, heating furnaces, etc., housed in a steel, brick, and concrete building 240 x 72-ft. Two electric cranes, of 50 and 30 tons capacity respectively, command the entire building. One press has a capacity of 600 tons, the other of 4,000 tons, at a steam pressure of 140-lb. per sq. in. (See accompanying plan of plant). The larger press has a distance of 128-in. x 64-in. between supporting columns,

single stroke, 7-in.; total stroke, 80-in.; weighs 740,000 lbs., and is adapted for forgings up to 75 tons in weight. As the presses are exactly similar, except in size, the following description applies to each.

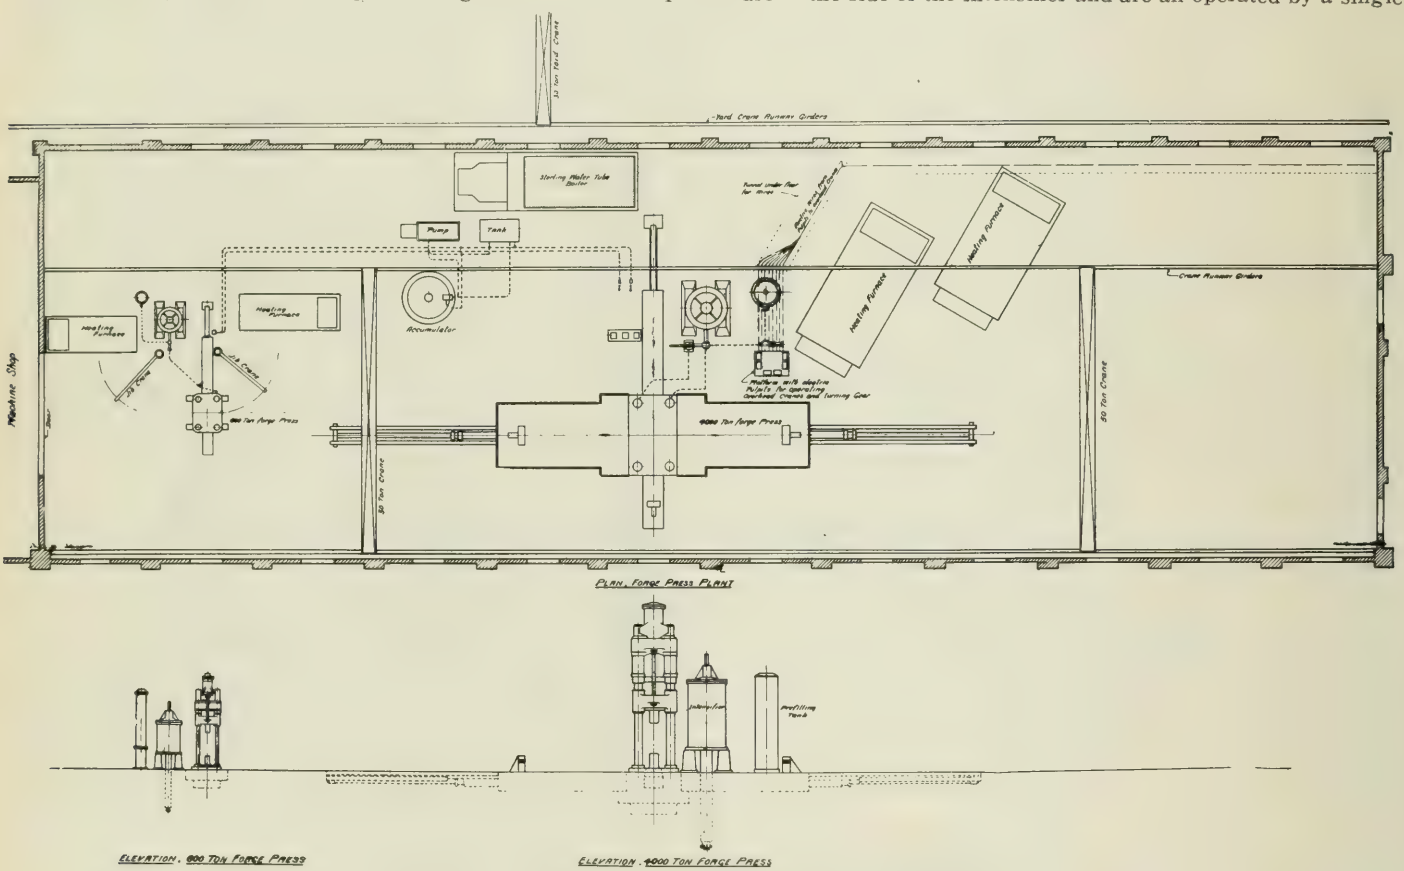
Each installation consists of the press proper, the pre-filling water tank and the patent hydraulic intensifier. The press consists of a heavy base plate, embedded in the concrete foundations, on which stands the anvil, also the four forged steel columns which support the press head. Situated near the top of the press are two return steam-cylinders, and the hydraulic or ram-cylinder which is located on the centre line of the press.

Immediately below the press-head is situated the press-traverse, the upper end of which is firmly attached to the piston rods of the three cylinders above referred to. Below the traverse is fastened the upper forging tool or tup. The traverse has four bushed guides, encircling and sliding on the supporting columns, to keep it in alignment and take up the heavy side strains when the ingot is not exactly under the tool centre.

The pre-filling water-tank is an air-chamber equipped with a pump for charging to a certain level at a pressure of 65-lbs. to the sq. in. This tank supplies water to the ram and intensifier cylinders and again stores the water which leaves the ram-cylinder when the piston rises, the flow being automatically controlled by a water valve.

The intensifier, which produces the high hydraulic pressure, consists of two cylinders, a large one, with steam actuated piston, placed immediately above a smaller one containing water. They have a common piston rod, the lower end of which, extending through and working in the water cylinder, acts as the plunger of a force pump. When the steam-cylinder piston moves upwards, the water is forced from an opening near the top of the lower or water-cylinder, at very high pressure, owing to the difference in their diameters, and enters the ram-cylinder giving a greatly increased pressure there. The intensification is 50 to 1, and gives a water-pressure of 3½ tons per square inch in the ram-cylinder.

This type of intensifier possesses many advantages over that of the ordinary type where the steam-cylinder is below, in that the design of the whole is lower, giving greater access to the working parts. The piston rod is always in tension, resulting in less wear and tear on glands which therefore are more readily kept tight. Vibration is largely eliminated by the valve arrangement which admits steam on the inside of the lower cover of the steam-piston, thus providing a steam cushion, and resulting in a noiseless drop. The valve system is automatic in controlling the press and prevents any injury to the tups or dies from below, due to momentum (for instance when cutting) for the weight of the tup is at once taken up by the under steam in the press traverse steam lifting cylinders. All the valves controlling the various operations are at the side of the intensifier and are all operated by a single lever, so adjusted that the press follows its movements in speed and stroke.



The Forge Press Plant of the Nova Scotia Steel and Coal Co., Ltd.

The press may be operated in four separate ways and under each the tup may at moment be arrested instantly and a new stroke inaugurated by a single movement of the controlling lever. The tup may be actuated (1), By the steam cylinders alone, the press then operating like an ordinary single acting steam hammer; (2), With intensifier giving high pressure only toward the end of the stroke. This is the method used in ordinary forge work; (3), With high pressure throughout the entire stroke, used in pure press work, cutting, etc.; (4), With intensifier and under steam-cylinders which results in rapidly repeated heavy blows delivered at a fixed height. This method is used for finishing work to exact size, the length of the stroke being automatically controlled.

The accompanying diagrammatic sketch of the operating cylinder and valve systems, showing the single lever control will make the mode of operating the press clear.

At all times steam pressure is acting on the under side of the press steam-piston, With controlling lever in position I., the top side stands open to exhaust. There is no movement owing to the water being confined over head of ram, the water valve, WV, being closed.

To lower ram, push the controlling lever down to II., thus balancing piston by admitting steam to both sides of it. Thus the weight of the press-traverse, assisted by the pressure of the prefilling tank (this latter having automatically opened the water valve) causes the ram to fall.

When using the intensifier, the hammer is dropped as already described, until it reaches the work, when the controlling lever is pushed down to position III. This raises the steam valve, SV, still higher, admitting steam to the large intensifier cylinder, ISC, thus forcing down ram of the press with the high pressure generated due to the difference in diameter of the steam- and water-cylinders or pistons.

By returning the lever to position II., the steam exhausts, and allows the intensifier-piston to fall; the vacuum thus formed drawing in more water from the prefilling tank. Upon pressing down the lever again, the pressure is again obtained from the intensifier.

This operation, of taking a new hold as it were, may be repeated throughout the total stroke, enabling pressing and cutting to continue at a uniform pressure for this distance. In this operation the oversteam is never open to exhaust.

Finally to obtain rapidly repeated short strokes, lower hammer to be required, then throw open the large exhaust valve. The steam is then admitted alternatively to the underside of the hammer-piston, and the intensifier-piston; this operation giving a heavy down-stroke and light up-stroke at any desired speed. To lower the range of these short strokes, open large exhaust valve, thus allowing the hammer to fall to desired height.

When making heavy forgings, whether under hammers or presses, the piece must be frequently moved and turned, especially when the finishing strokes are being given. To do this speedily and cheaply, a mechanical handling equipment has been installed, the forging being suspended and rotated by an endless chain driven by electric gear attached to the forging crane. This crane may be operated from the usual suspended cage and also from a pulpit at floor level, close to the presses. Hydraulic manipulator and mandrel gear is provided for forging long massive shafts, cylinders and turbine casings, etc. There are two hydraulic operated rests on each side of the big press for supporting long forgings. These travel twenty feet each way. Hydraulic manipulating gears are provided for adjusting the different bottom anvils. On the large press, the stroke of this appliance is about 12 ft.

The low pressure hydraulic installation operating this mechanism consists of a dead-load accumulator supplied by an electrically-driven three-throw vertical pump. The motor is 50-horse-power, and the pump supplies 50 gallons per minute against a working pressure of 720 lbs. per sq. in. in to the accumulator ram.

Rapid working, range of utility, economy and every other requirement of modern forging practice are fulfilled by this plant. The steam consumption is extraordinarily low as the cylinders do not have to be kept filled continuously. The plant is exceedingly compact and with its wide scope and splendid equipment of accessories, will be able to furnish all the Canadian requirements in forgings for years to come.

From the view-point of the consumer, the product of the steam-hydraulic forging press has many advantages. This is not only because forgings may be produced at a lower cost, for the improvement in the quality of forgings is even more important.

The product of a modern steam-hydraulic press is denser and more homogeneous than can be provided with the steam hammer, due to the effect of the blow of the latter not penetrating to the centre, in contradistinction to the uniform kneading effect of the press; while the amount of work that can be done by the latter at one time, with little variation in temperature, strongly tends to produce a better product. This simplifies the required heat-treatment by reducing the number of heating and their duration. It also prevents the liability of damage due to working at a blue heat. Thus the greater uniformity and reliability of steam-hydraulic forgings makes their use imperative wherever high-class forgings are necessary.

PROPOSED MONTREAL HARBOR IMPROVEMENTS.

According to a plan of improvement recently spoken of by the harbor commissioners of the Port of Montreal, it is proposed to expend from $1,500,000 to $2,000,000 on improvements in the west end of the harbor. The harbor of Montreal has a length of many miles, but the central or upper portion is no more than about half a mile in length. The harbor commissioners' office is close to the mouth of the lower entrance of the Lachine Canal, and from here down to Bonsecours market is situated the harbor of Montreal, as it is known to all the passenger boats and most of the large carriers of general merchandise. Here are situated the big elevators which take the grain from the upper lake vessels and tansfer it into the holds of the ocean liners. These elevators are equipped with carrying belts which discharge cargoes into vessels docked at any point along the wharves of the upper harbor. Passenger steamers all dock in this vicinity and the regular passenger companies have their offices not far distant.

Owing to all these advantages, as well as to the ease with which freight can be handled from ships docking in this vicinity to the importing and exporting houses, as well as to the railway depots, space for dockage is most desirable and there is greater demand for it than there is supply.

The harbor commissioners now propose to build a twelve hundred foot concrete pier straight out into the river from opposite the offices of the habor commission, at the foot of McGill Street. This locality is now used as a basin for vessels entering or leaving the canal, the entrance to which is nearby. As the entrance to the canal would be made difficult by the construction of this new pier, the plan includes the moving of the entrance to a point a convenient distance further west. Other improvements include the deepening of some of the old basins and the construction of other new concrete wharves, together with the lengthening of three of the principal piers now in existence, namely, King Edward, Alexandra, and Jacques Cartier piers, each of which will have 300 feet added to them. The completion of the new pier at McGill Street will provide accommodation for at least two more large ocean steamships, while the lengthening of the piers referred to and the completion of Victoria Pier, will increase the capacity of the central and most valuable proportion of the harbor by a very considerable percentage.

Meantime, work is proceeding on the completion of more elevator capacity, and on various other improvements which have been undertaken. Additional permanent sheds are being planned for the extensions which are being added to the piers and for the new piers, and it is believed that the commissioners have under consideration improvements in the way of railway facilities, to and from the ships, which will greatly facilitate the handling of freight.

THE INFLUENCE OF ICE ON WATER POWER DEVELOPMENT.*

By H. T. Barnes, D.Sc., F.R.S.†

The industrial development of our vast water powers is of great interest to everyone looking to the future. As public utilities become more and more dependent on hydraulic power, the question of continuous operation is of far-reaching importance. Chief among the causes which affect uninterrupted service is the presence of ice, which for five months of the year forms in the water. Hitherto it has generally been accepted that disturbances from ice inevitably occur, bringing about temporary "shut-downs." It has been thought necessary in every well-designed plant to instal an auxiliary steam plant to carry the load, and so far as the public is concerned, little is known outside the power house. It cannot be said that this is desirable, and in the future big developments is will be too costly. That it is not necessary it is my desire to point out in the present paper. The matter is creating not a little interest among engineers who have had personal experience of ice troubles, and the public generally are beginning to awaken to the fact that inconvenience from the stoppage of the power is not to be allowed. During the days of small developments it was a matter of little importance; but in the near future an abundance of cheap power will become available that must not be subject to caprice of Nature. Continuous service must be preserved if the confidence of the public is to be gained, and the wealth of power around us utilized to its full capacity. Canada has a great inheritance in its water powers. She is also blest with a vigorous winter, so that a study of ice conditions is of increasing importance.

Nowhere can one find a more wonderful example of the delicate poising of the forces of Nature than in one of our northern rivers. As soon as winter sets in, the water cools to the freezing point, and varies but a few hundredths of a degree for the entire period of ice production. The reason is to be found in the particular nature of the freezing process. Every liquid which produces a crystalline solid has a definite freezing and melting temperature, which we are told never varies. The process of change involves a heat transfer without temperature change. We know, however, by the second law of thermodynamics that heat cannot pass from one body to another without a temperature difference. The latent heat of water cannot pass out without a temperature gradient be it ever so small. In the case of water the molecules give up their heat readily when changing to ice, and the change proceeds rapidly when the temperature difference is only a small fraction of a degree. The microthermometer has revealed the magnitude of these temperature differences which have escaped detection in the reading of the ordinary thermometer. Thus when ice is forming rapidly, the temperature is found to be of the order of a hundredth of a degree below the freezing temperature, and the heat flows out of the molecules to keep the water from going lower. Similarly, when ice is melting rapidly, the temperature rises slightly. As a rule, ice forms, and that which is already formed, grows when the temperature is only a few thousandths of a degree lower than 32° F. Water can crystallize at a certain rate. When the heat loss is rapid, the temperature falls, thereby accelerating the ice production and preventing too rapid a growth. Similarly, ice can melt only at a certain rate, and the rapid supply of heat results in a slight rise of temperature in the water which accelerates the melting. A mixture of ice and water is at the true freezing point only when it is neither gaining nor losing heat. Rapid freezing or melting results in a temperature slightly lower or higher than this. Hence we find the balance in Nature continually swaying one way or the other, depending on the outside conditions.

It is doubtful whether the ice itself wetted on the surface ever differs from the true freezing point, since the surface of the crystal emits or parts with the latent heat, and is thus continually surrounded by a source or sink for the heat produced. The birth of an ice crystal takes place by the disturbing influence of foreign matter in the water such as fine particles of denudated material and by the direct action of cold air churning up the surface into spray which falls back frozen. The vapor from open water also furnishes the nucleus for the ice crystal, and the beautiful ice flowers noticed on a very cold day on thin ice are caused by the freezing of these particles. The steam noticed on a cold day from open water is a direct sign of the comparative warmth of the water, and must supply a vast number of small crystals which fall back into the current.

There are three distinct forms of ice met with in Nature; there are, surface ice, frazil ice and anchor—or ground—ice. Of these, frazil ice is the most troublesome to power houses, and causes probably all the "shut downs." I will briefly describe all these forms.

Surface Ice.—Wherever water is still, ice forms rapidly over the surface and closes it in. This ice starts in two ways, depending on the general weather conditions. It may spread over the surface quietly, commencing from the shore and working outward, forming a sheet that is smooth and often clear, but it forms more often from the freezing of the frazil and scum ice blown by the cold wind into the bays or inlets. In this case the ice grows backwards against the wind, being increased by the fresh accumulations. This surface layer is rough and opaque, and consists of large and small pieces with the crystal pointing in every direction. While the first method of freezing requires absolutely quiet conditions, the second will often proceed over the surface of quite a rapid current. In both cases the water must be at the freezing point; and the heat carried off by the cold air. The effect of a wind is to increase very much the heat loss, and, therefore, the second method is the one which causes the more rapid freezing. Evaporation from the surface furnishes a large part of the heat loss due to the high latent heat of vaporization. Hence a wind from the north with little moisture in it will produce more evaporation and a greater ice production than one of the same temperature from the east or south. But, as a rule, a north wind is accompanied by fair weather, and sunshine inhibits the ice production to an enormous extent. An east wind with clouds and snow often causes vast numbers of crystal nucleii in the water.

As soon as the first ice layer forms, by whichever method, the wind is shut off from the surface, and scum ice is no longer formed. The ice sheet now grows rapidly in thickness by the conduction of heat through the ice to the cold air above. The rate of growth of ice may be calculated from ordinary data of heat conduction. The velocity of the wind and the rate of evaporation of the ice surface also determines the rate of growth. Presumably the water under the ice is at 32 deg. Fahrenheit and layer after layer of ice is frozen on. The ice thus produced is of great purity, since the freezing proceeds so gradually that air and frozen matter are readily expelled. It is always possible to tell this ice from the first layers, as it is clear and hard. The crystals are all grown with the main axis at right angles to the surface. Hence when the surface becomes rotten in the spring, the ice often consists of a lot of vertical needles standing on end. A wind or current will topple these over, and they quickly melt, giving rise to the

*Abstract of paper presented at annual convention of Canadian Electrical Association, Ottawa, June 19-21, 1912.

†Macdonald, Professor of Physics, McGill University, Montreal.

tradition that surface ice sinks in the spring. Surface ice grows more and more slowly as the thickness increases, until it finally becomes stationary. It then proceeds to melt and decreases in thickness until the warm sun of April rots it away.

There is a limiting thickness to the surface ice which is determined by the temperature of the water under the ice. In our rivers the water gently flowing along the under surface of the ice is seldom exactly at the freezing point. This is due to not only the natural heat of the river bottom, which is entrapped in the water flowing over it, but also to the increasing power of the sun in the late winter months. The limiting thickness of the ice is due to this, and the decrease towards spring to the rising water temperature. The average water temperature under the ice is about 1/100th of a degree as shown by the microthermometer. In cases where undercurrents are brought to the surface, we find what are called air-holes in a lake or river otherwise frozen over. This is due to the higher temperature at these places which prevents the ice from growing, and rapidly melts any surface layer formed at the outset of cold weather.

Surface ice, when it can be induced to grow, is a protection to the water, and prevents scum and frazil ice, but also holds the water temperature back long into the spring, turning back the greater part of the sun's heat. Water running under surface ice faster than half a mile per hour, will carry with it floating ice. Attention must be directed to this whenever an intake is situated in open water. Surface ice may also prove to be a menace and a continual source of trouble, as will be better understood when frazil ice is described.

Frazil Ice.—Frazil, as its name implies, is cinder-ice, so-called by the French from its resemblance to cinders or ashes. It is the fine needle ice found floating in the open water, and varies in size from minute crystals to large agglomerated masses. It is formed by surface cooling in water flowing too swiftly for surface ice to form. An estimate of the number of these crystals in a cubic foot of water shows on an average cold day in winter about a quarter of a million, but this I have found often reaches several millions. The current carries these crystals downwards and under the barrier of surface ice which extends over the quieter parts of a river, and there they settle upwards and become attached to the under side of the surface sheet. In a short time immense hanging dams are produced which impede the water course and cause a rise of the water level. During cold weather the under passages may become blocked entirely and a rapid rise of water produced above the dam. When sufficient head of water is gained, the whole ice jam is forced out and a winter "shove" produced. At some parts of the river, like the St. Lawrence, there is a continual rise and fall of water level going on all winter. This frequently interferes with the normal head of a power house and causes serious trouble.

During the period of rapid formation of frazil ice, the water is slightly below the freezing point, and, in consequence, the crystals are growing rapidly. They readily freeze and form agglomerated masses, and they attach themselves to objects immersed in the water which are likewise cooled slightly below the freezing point. The time during which supercooling takes place does not last very long, and is quickly relieved during the periods of fine sunny weather.

Anchor Ice.—Whenever a river is open in winter, the presence of ice growing on the surface of objects immersed in the water is observed. This ice forms in long needle crystals attached in the same manner as the ice flowers. As the ice thickens, the crystals become large, and finally form masses many feet thick of coarse-grained crystals. Anchor ice forms primarily from the cooling of the river by radiation. Water is an almost perfect absorber of heat, and, likewise, it is an almost perfect radiator. During the intense radiation at night in winter when the sky is clear and the air almost devoid of water vapor, the water and objects in it become supercooled. Ice forms rapidly and covers the entire river bottom. During the day the effect of the sun is to raise the water temperature slightly, and the ice soon loosens and rises to the surface.

Anchor ice plays little part in power house troubles, for during the period of frazil sticking, the anchor ice is frozen to the bottom and held in place. In fact, it appears to remove many of the frazil crystals in as much as it is growing rapidly and readily causes an adhesion of the fine needle crystals.

Power House Location.—A power house may be situated at a rapid or fall where the water normally freezes over for many miles above. As soon as the winter ice is formed, usually no trouble from ice need be feared. Until, however, the river closes in, a period of frazil production may result and consequent closing down of the plant.

Sometimes open water conditions above compel a long forebay to be constructed where the surface ice is allowed to form. If the forebay is fed from open water, frazil jams are sure to occur, and the free waterway reduced or stopped altogether. It is better to run a canal up to the position of permanent surface ice to avoid this. When jams occur, little can be done beyond blowing up the ice by dynamite and blasting out a clear channel. In this case men must be stationed to remove the frazil from the channel, as the ice is drawn in by the current. When a forebay is fed from open water, it is better to keep it from freezing and handle the ice at the power house.

Ice troubles at the power house show themselves in the freezing of the racks, gates and turbine wheels. Special heating devices must be provided to avoid the sticking and freezing of the frazil crystals. The ranks must be protected from the direct action of the cold air by a curtain wall, and may to advantage be heated. The iron bars of the rack when exposed draw the heat from the water and cause an abundant supply of anchor ice even when the water is not supercooled. By enclosing the racks, the natural heat of the water has full effect, and usually nothing is needed to keep them free of ice.

When a power house is fed from open water, at times frazil may come down in such quantities as to stop the racks mechanically. In such a case the ice can be removed mechanically. Revolving racks would be of great service under such circumstances. For the turbines and gates steam-heat may be used, as in Mr. John Murphy's appliances. It is only necessary to keep the surface of the machinery a very small fraction of a degree above the freezing point, and this can be done easily. Mr. Murphy, who has already read a paper before this association on ice troubles, has been wonderfully successful, and a visit to the Ottawa and Hull Power Company will show the practicability of his apparatus. Repeatedly the stations equipped with his units have been running when neighboring stations not so equipped have been shut down with not a wheel turning.

The tail race sometimes causes trouble when the ice jams below and causes the level to rise. This is the most difficult to deal with. It involves dealing with the channel below, which is often too costly for a small development. By maintaining an open channel below, trouble of this kind can be avoided. In general we can give some rules for avoiding ice troubles:—

1. Have covered racks and steam-heat provided for the trouble which always comes to a power house before the permanent ice forms.

2. Instal a few meteorological instruments to watch the weather in order to be prepared for the first cold snap.

3. Where the forebay is fed from a lake or canal, induce freezing as soon as possible: otherwise maintain an open channel down to the power house. Provide a special way for floating frazil.

4. Watch the temperature of the winter at the outset of cold weather, and when 32° F. is approached, have the steam-heating plant in readiness.

CONVENTION OF AMERICAN WATERWORKS ASSOCIATION.

The members of the above association held their thirty-second annual meeting in Louisville, Ky., on June 3-8 last. Mr. Dow R. Gwinn, of Terre Haute, Ind., presided in the absence of the president, Mr. Alexander Milne, of St. Catharines, Ont.

After the reports of the various committees had been presented several papers dealing with matters of interest to the members were read and discussed.

Three papers dealing with efficient management of large works were presented by Mr. Harrington Emerson, of New York, Mr. E. C. Church, of New York, and Mr. I. M. de Varona, also of New York.

Prof. Albert F. Ganz presented an illustrated paper on Electrolysis from Stray Electric Currents.

Considerable discussion followed the reading of papers on "Water Waste," by Mr. Edward S. Cole, of New York, and Mr. F. H. Shaw, of Lancaster Pa. Mr. Reimer mentioned in the course of the discussion that East Orange, N.J., had reduced the per capita consumption from 93 to 80 gallons by combined inspection and metering 25 per cent. of the services.

Dr. D. D. Jackson's paper on "Results of Chlorination at Cleveland, Ohio," was illustrated with lantern slides. He outlined the seasonal and geographical typhoid distribution in Cleveland as well as at a number of other cities. Valuable tables on typhoid rates for the past three years in 16 cities having populations of 100,000 and over with a filtered water supply showed up the large amount of typhoid that is due to general sanitary conditions. Relative percentages of typhoid rates in Cleveland he classified as follows: 10 per cent. of the water supply, 10 per cent. to out of town cases, 10 per cent. to raw foods, 30 per cent. to general sanitary conditions and 45 per cent. to contact cases.

An open discussion followed the reading of this paper which ended by resolutions being passed urging upon boards of health the importance of ascertaining and recording the distribution of typhoid fever by causes and modes of infection to the end that a division of responsibility may be made between water supply, contact cases, general sanitary conditions, milk and other food supplies liable to contamination and typhoid carriers. It was further resolved that boards of health be urged to do their full duty in the elimination of all causes of the spread of typhoid fever, including the use of polluted private wells, or other polluted water, when a pure public water supply is available.

The election of officers for the coming year resulted as follows: Mr. Dow R. Gwinn, Terre Haute, Ind., president; Mr. Robert J. Thomas, Lowell, Mass., first vice-president; Mr. John A. Affleck, Harrisburg, Pa., second vice-president; Mr. George G. Earl, New Orleans, third vice-president; Mr. Theodore A. Leisen, Louisville, Ky., fourth vice-president; Mr. Charles R. Henderson, Davenport, Ia., fifth vice-president; Mr. J. M. Diven, Troy, N.Y., secretary and treasurer; Mr. H. E. Keeler, of Chicago, Mr. Leonard Metcalf, of Boston, and Mr. Leslie C. Smith, of Cleveland, finance committee.

The convention next year will be held in Minneapolis.

TESTS OF STEAM TURBINES.

The results of the following tests on the Zoelly steam turbine are of considerable interest. The capacity of the turbines ranged from 1,250 k.w. to 10,000 k.w. The resulting steam consumptions are of interest on account of the low figures obtained, and from the fact that the increased consumption at partial loads is kept within very narrow limits when it is remembered that the efficiency of the generator is decreased considerably when running at loads below normal. The figures from the official tests have been furnished us by Mr. T. Heyerdahl, chief engineer of the Escher-Wyss Company in Canada:—

Two 1,250 k.w. Zoelly turbines, 3,000 r.p.m., delivered to the municipal power station at Drammen, Norway; in commercial operation since January, 1912. The official test was carried out February 19th and 21st. 1912:—

Load.	Full.	Three-quarters.	Half.
Power in k.w., inclusive of excitation, but exclusive of power required for the condenser	1,275	981	656
Over-pressure at stop-valve of turbine in lbs. sq. in.	183.0	174.5	174.0
Temperature at stop-valve, deg. Fahrenheit	588	494	472
Vacuum at the exhaust branch in inches (referring to 30-inch mercuri)	29.06	29.22	29.42
Steam consumption in lbs. per k.w. and hour	12.60	13.80	14.80

One 5,000 k.w. Zoelly turbine, 1,500 r.p.m., delivered and installed at the power-house of Escaut, near Antwerp. The official test was carried out January 22nd and 23rd, 1912:—

Load.	Full.	Three-quarters.	Half.	Quarter.
Power in k.w., inclusive of excitation, but exclusive of power required for the condenser	5,418	4,305	3,160	1,184
Over-pressure at stop-valve of turbine in lbs. sq. in.	167.0	168.0	173.5	169.5
Temperature at stop-valve, deg Fahrenheit.	588	556	559	520
Vacuum at the exhaust branch in inches (referring to 30-inch mercuri)	28.90	29.10	29.26	29.55
Steam consumption in lbs. per k.w. and hour	11.92	12.32	12.65	14.70

One 10,000 k.w. Zoelly turbine, 1,250 r.p.m., delivered for La Société le Triphase à Asnière. Officially tested February 12th, 1912:—

Load.	Full.	One-third.
Power in k.w., inclusive of excitation, but exclusive of power required for the condenser	10,006	3,678
Over-pressure at stop-valve of turbine in lbs. sq. in.	154.0	162.5
Temperature at stop-valve, deg. Fahrenheit	566	567
Vacuum at the exhaust branch in inches (referring to 30-inch mercuri)	28.72	29.19
Steam consumption in lbs. per k.w. and hour	12.00	14.52

STANDARD HOSE COUPLINGS AND HYDRANT FITTINGS.*

By F. M. Griswold.†

The first concerted attempt to secure the adoption of a standard hose coupling dates from the organization meeting of the "National Convention of Fire Engineers," in Baltimore in October, 1873, when with the lesson of the great Chicago fire of 1871, added to that of the conflagration in Boston, November, 1872, before them, this assemblage of fire chiefs adopted the following resolution: "Whereas, experience has shown that the fire departments of the country should be provided with a universal or standard coupling for hose and fire hydrants, so that when a city or town calls for aid, in case of large fires or conflagrations, from another city or town, that each department can act in unison with the other; therefore, be it resolved that a committee be appointed by this convention to take under consideration, and report back to this Convention the practicability of adopting a standard coupling of some kind to be used by all fire departments throughout the United States."

The standard thus established was of 2½-in. inside diameter, 3 1/16-in. outside diameter over thread of male end, with 7½ threads to the inch. Some chiefs changed their couplings to conform to this and have since maintained that standard in operation. But standardization failed of immediate accomplishment because no concerted and continued action was undertaken to keep the proposition alive.

The firemen's convention of 1875 adopted as its standard a coupling showing 2⅝-in. inside diameter, by 3⅛-in. outside diameter "exclusive of the thread" and of 3⅜-in. outside diameter inclusive of the thread, the latter to be 8 to the inch. In 1878 a special committee reported that the 1875 specifications were found to be "impracticable in use."

In 1879 the firemen again took up the subject and this time submitted as their standard a coupling showing 2½-in. inside and 37/32-in. outside diameter with six V-shaped threads to the inch, which was duly adopted. The matter lay dormant until 1883, when the 1879 specification was endorsed and resolutions passed to secure co-operation through state legislation.

In 1890 the Firemen's convention appointed a committee to report a standard for adoption in 1891. Mr. C. A. Landy, chairman of the committee presented a report covering coupling dimensions in 1339 towns where 2½-in. fire hose was in service, showing outside dimensions over male ends ranging from 3 to 3⅜-in. and including 7, 7½ and 8 threads to the inch. Having demonstrated by the use of a model coupling of 3 1/16-in. outside diameter, with 7½ threads to the inch, that about 70 per cent. of the couplings listed might serviceably be converted to use with a coupling of these dimensions through the simple process of decreasing the diameter of the male thread, or of increasing that of the female swivel, he urged the adoption of a standard conforming to these dimensions as an intermediary which would permit standardization at the least expense.

The feasibility of adapting these non-conforming couplings to practically serve with the proposed standard carried conviction to the members of the Convention and a standard for 2½-in. hose was adopted under specifications showing 3 1/16-in. outside diameter over male end, with 7½ threads to the inch, but in nominating the number of threads for the larger sizes of couplings, the committee then having the matter in charge, increased them in ratio proportional to the expansion in diameters, thus presenting a mechanical anomaly not to be tolerated in practice.

For thirteen years after the adoption of a standard in 1891, which action was simply an endorsement of the specifications of 1873, the hose coupling proposition appears to have reposed in undisturbed quiet.

Confronted with this record of 31 years of failure, the National Fire Protection Association selected the writer as its delegate to the convention of the International Association of Fire Engineers at Chattanooga, in 1904, instructing him to propose joint action to devise an acceptable coupling. This proffer of co-operation was accepted and a committee appointed to take charge of the work.

This committee suggested as a standard coupling for 2½-in. hose one showing a diameter of 3 1/16-in. over male end thread, with 7½ threads to the inch, by the use of which it was practically demonstrated that couplings ranging in outside diameter from 3 1/32 to 3 5/64-in., with either 7, 7½ or 8 threads to the inch, could be so modified as to serviceably couple-up with this suggested standard, and thus render over 70 per cent. of the majority couplings known to be in use conformable to the proposed standard at small expense.

The committee took the matter up with the Insurance Committee of the American Waterworks' Association in April, 1905, at which there was also present a number of the associate members of the Association. The specifications were critically considered and accepted without change, and were adopted by the Association in 1905. The writer also presented the proposition to the International Association of Fire Engineers at Duluth, 1905, when the convention voted almost unanimously in the approval of the standard specifications. Following this action at Duluth the committee secured other approvals of the standard from important organizations.

When this proposition was first presented to the American Waterworks' Association the committee held data relating to couplings' dimensions in only about 1,600 separate localities in this country. Since that time it has created a card index record covering 3,133 towns in the United States and Canada. Analysis of the data shown in this record, based upon actual results accomplished in the conversion of non-standard couplings to safely interchange with the established standard, demonstrates that approximately 80 per cent. of the couplings listed are either of standard dimensions or may readily be so modified as to conform to them.

The record shows 73 cities in which the standard has been put into service, seven of these installations including the complete substitution of standard couplings and hydrant nipples in place of previously prevailing non-standard devices.

In St. Louis, Mo., over 11,000 hydrant outlets and the couplings on many thousands of feet of fire-hose were changed from 6-thread to the standard by city employees, at an average net cost of $1 per hose coupling, and $2.82 per hydrant outlet, the latter being principally of 4½-in. steamer suction type, each of which was laboriously chipped-out by use of a cold chisel.

During the winter of 1910-11, Sprinfield, Mass., discarded the Universal clutch coupling and substituted for it the standard, changing over 1,350 hydrants, some of which had four outlets, at the rate of from 50 to 100 outlet replacements per day, at an average net cost of $1 per outlet, giving credit for the old metal, and excluding cost of labor performed by the regular force of water-works employees. Couplings on 2,000 feet of hose were changed by department employees at a like net cost of $1 each.

This work was carried out in the winter. Where hydrant nipples were leaded-in, the use of a 6-lb. sledge proved an efficient means for their removal, while in the case of screwed-in nipples, an expanding wrench entered from the out-board end of the nipples engaged the operating lugs and permitted the easy removal of the device, while the 4½-in. leaded-in suction nipples were melted out by a plumber's blow torch, at the rate of 5 minutes per operation.

*Abstract of paper presented at 32nd annual convention, Louisville, June 3rd to 8th, 1912.

†General Inspector, House Insurance Co., New York.

NEW TYPE OF STEEL FORMS.

The increased use if concrete for pipe and conduit manufacture has made time and energy spent in form improvement profitable, and from this fact is due the many and satisfactory methods of conduit manufacture now in use.

Many of these machines manufacture the pipe in sections, which are so formed at the ends as to allow them to be bonded together. The "Blayney" system recently patented, allows the conduit to be constructed in one piece, and presents some features worthy of comment. A description of the system follows:

Wooden forms are bulky and clumsy to handle; they shrink and swell; are difficult to clean; costly to repair each time they are used and are useless after being used a few times. Wooden forms are expensive because they require skilled labor to handle and without special care they will leave a rough surface which is objectionable in many concrete pipes.

Extensive use has demonstrated the desirability of using steel forms. Their first cost is more than that of wood, but the total cost of steel forms is much less than the total cost

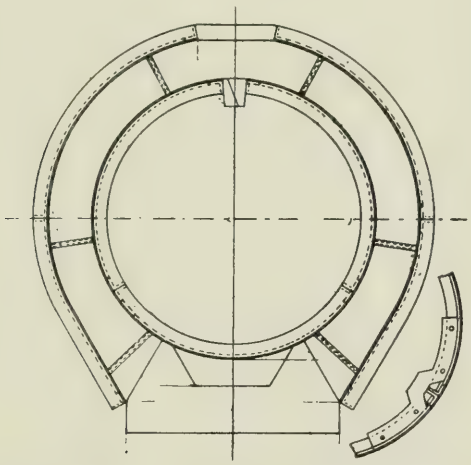


Fig. 1.—End Sectional View of "Blayney System" Collapsible, Telescoping Steel Forms and Centering.

of wood forms. One set of steel forms is sufficient to complete the longest pipe in existence, or contemplated, and still be good, providing only reasonable care is exercised. The steel forms will leave a smooth surface, so that little pointing of the concrete is necessary.

The advantages of steel forms and centering are many. They are callapsible and telescoping, so that no forms are idle. Therefore less forms will do more work, because they are all in use at all times during the progress of the work. The forms will either be ready for pouring the concrete or supporting green concrete. As soon as the concrete is sufficiently set, the forms can be taken down, collapsed, and passed through the forms ahead and re-assembled ready for concreting without interfering with the concreting of the section that is already being poured.

A pipe built with this system is a continuous concrete monolith, built, or poured, in sections of whatever length constitutes a day's work. This may be twenty feet or it may be one hundred feet or more. The total circumferential section should be built in one pouring and in that way avoid all horizontal seams or joints.

The dove-tailed bulkhead is removed, and each succeeding day's concreting is poured against the green dove-tailed end of the previous day's work. This method secures a bond and an even bed is secured for the pipe.

The forms are made of sheet steel, bent to the required shape, with stiffeners or ribs of angle iron riveted to the plate. They are made in segments bent to conform to the contour of the desired pipe. For a round pipe the segments are symmetrical and therefore interchangeable. This adds to the speed with which the forms can be erected. Each

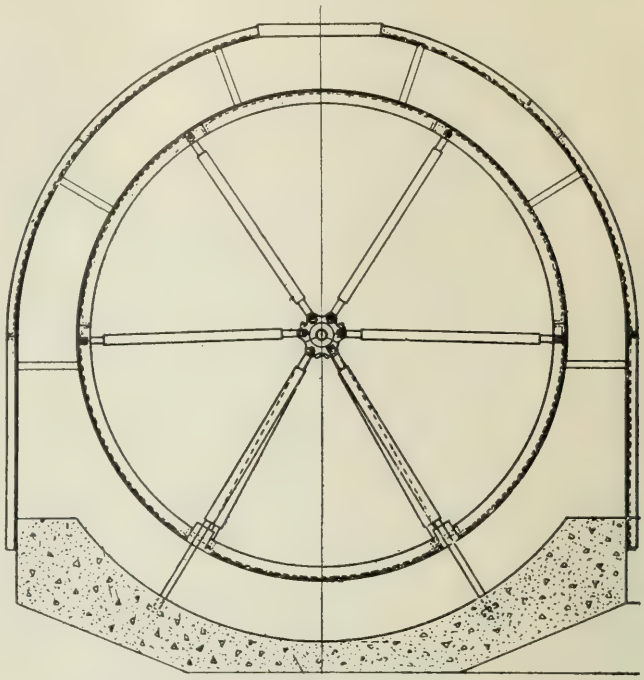

Fig. 2.—The System Used for Building Large Concrete Pipes.

segmental section of inside forms is small enough to allow it to pass through the forms ahead. Each segment is bolted to its adjoining ones, making, when assembled, a rigid form.

The outside forms may be built up as the concrete rises, thus allowing working space for tamping the concrete.

For pipes larger than seven feet it is necessary to have inner bracing. Figure 2 shows this bracing. It consists of a longitudinal central shaft on which is a cast iron collar which is shown in Figure 3. This shaft is supported by two legs running from the footing in bottom trench, or saddle, as the case may be, to the cast iron collar on the central shaft. By means of left and right hand male and female threads a turnbuckle effect is produced on these legs and they may be shortened or lengthened at will. This forms a simple and efficient method of holding the central shaft and consequently the whole form to line and grade.

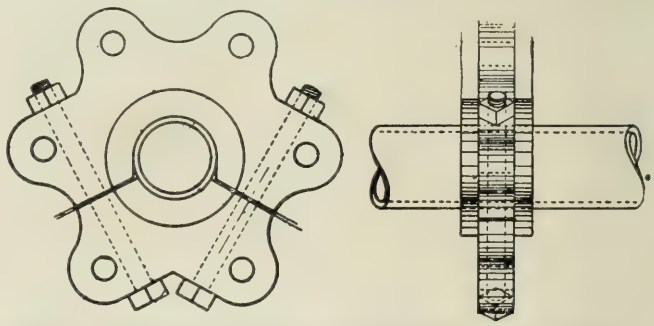

Fig. 3.—Cast Iron Collar on Central Horizontal Shaft.

From this central shaft run arms also having this turnbuckle attachment to regulate and hold the segments to their proper positions.

Like the smaller pipe forms each segment of the inside forms is interchangeable and will pass under the central shaft and between the supporting legs which holds the shaft. This will enable workmen to be placing new forms daily without interfering with the concreting of the forms

already erected. The outside forms are held in position by being accurately spaced from the inside forms by pipe separators which may afterwards be grouted.

The system is not restricted to the building of round concrete pipes as these forms are designed for and will readily accommodate themselves to the building of any pipe from round to square. The forms will take care of a curve or bend in any direction.

The system adapts itself to almost any style of reinforcing required to make the pipe sufficiently strong for its particular use. The hollow pipe separators afford an admirable chance to wire the steel to them, thus holding the reinforcing securely in place.

These forms are manufactured by the Standard Steel Form Company, Niagara Falls, Ont. The system is known as the Blayney System. The above company manufacture these forms to order. They are for sale, or lease to municipal and other corporations contractors, owners, or others who are interested in or responsible for the construction of all kinds of plain or reinforced concrete pipe, including concrete culverts, canal walls, conduits, trunk sewers, sanitary and storm sewers, twenty-four inches in diameter and over, pressure pipes of concrete for all purposes, water mains, concrete tunnels through soil, rock or water, and subways for electric, steam or other railways.

DOMINION IRON AND STEEL COMPANY, LIMITED, SYDNEY, N.S.

While the following is not intended as a complete description of the illustration which is shown in connection with this article, some of the major points in connection with same may prove of interest to our readers.

When the Dominion Iron and Steel Co. decided to extend the iron producing portion of its plant it was decided to parallel the present blast furnaces, known as Nos. 1, 2, 3 and 4, with another complement of four furnaces some 400 feet to the westward of the furnaces now operating. As all the plant units are numbered from the north to the south, it will explain how the fifth furnace of the installation was called No. 8, as the construction began from the southern end of the new plant addition.

The old plant was designed and constructed under the direction of Mr. Julian Kennedy, Pittsburgh, during ten years of operation, and has been more or less altered. With this information and precedent at hand the Dominion Iron and Steel Co. contracted with the Canada Foundry Company for the erection of the No. 8 furnace, and at a later date for No. 7 furnace, which is the opposite end of No. 8 and of equal capacity.

The illustration shows the general view of the stack, stoves, stove shelter, furnace proper and cast house from the northwest side of the plant, including also portion of the skipway where it joins the bin system. This No. 8 furnace is the second furnace to be constructed in Canada by the Canada Foundry Co., Limited, they having completed a contract for the construction of the furnace for the Atikoken Iron and Steel Company, at Port Arthur, some four years ago.

The Canada Foundry Company has recently closed contracts for a portion of the work in connection with the new Canadian Furnace Company, Limited, at Port Colborne, Ont. These facts clearly establish that this class of construction can readily be obtained in Canada.

We believe that those interested in this class of engineering work who will look into the matter carefully will find that Canada has ample facilities and skill to execute all work in connection with our metallurgical developments to the entire satisfaction of all concerned.

We hope to supplement this short article from time to time with other various details of interest in this connection and at an early date furnish complete description of the above extensions referred to at the Dominion Iron and Steel Co., Sydney, N.S.

EFFICIENCY TESTS OF IMPULSE WATER-WHEELS.

The accompanying curves show the results obtained in recent tests on impulse wheels designed and installed by Escher Wyss & Company, of Zurich, Switzerland, whose Canadian head office at the Canadian Express Building, Montreal, is under the supervision of Mr. T. Heyerdahl, chief engineer. The results of the official tests as shown in the curves are exceedingly interesting on account of the efficiencies obtained.

The Adamello plant is situated on the border between Switzerland and Italy. The curve relates to an impulse turbine installation working under an effective head of 3,000

feet, each unit being designed for a maximum power of 6,600 B.H.P., when running at a speed of 420 revolutions per minute. These turbines are all of the Escher Wyss Company's special design and patent, fitted with deflecting nozzle which eliminates the employment of any relief valve, at the same time keeping the rise of pressure in the penstock remarkably low. As a matter of fact, when tests were made and the full load was thrown off, the pressure at the end of the penstock

only rose to a very few per cent. above normal. The above efficiency curve which exceeds the guaranteed figures by about 8 per cent. is remarkable by the fact that it remains above 80 per cent. from over-load to one-quarter load. A general description of this plant was given in The Canadian Engineer of August 31st, 1911, where full details of the installation were given.

The Robbia plant is situated on the border of Switzerland and Italy.

This curve relates to the same type of turbine as above described, the effective head being 1,900 feet, and each unit

having a capacity of 3,500 B.H.P. when running at a speed of 500 revolutions per minute. This curve is also remarkable on account of the efficiency remaining above 80 per cent. from full load to almost one-quarter load.

ECONOMY TESTS OF STEAM TURBINES.

The table herewith is part of a paper on the "Present State of Development of Large Steam Turbines," read at the spring meeting of the American Society of Mechanical Engineers by Prof. A. G. Christie, of the University of Wisconsin. With regard to this phase of the subject he says:—

The efficiency of a steam turbine may be expressed in terms of pounds of steam per kilowatt-hour, as an efficiency ratio or as the B.t.u. required per kilowatt-hour.

The steam consumption is dependent on the initial steam pressure, its temperature or quality, and the condenser pressure. These factors vary in almost every test and the effect of a variation in each is not the same for all classes of turbines. Hence, different turbines cannot usually be compared satisfactorily on the basis of their steam consumption alone.

If the steam could expand freely to exhaust pressure in a turbine without radiation, friction, eddy or windage losses, its expansion would be adiabatic and on the Rankine cycle. The "efficiency ratio" expresses the proportion of the heat actually turned into work to that available from such an adiabatic expansion; in other words, it expresses the efficiency of the actual turbine as compared to the ideal turbine, and is independent of the type of turbine.

The B.t.u. per kilowatt-hour is figured above the heat of the liquid at exhaust pressure. This is not a satisfactory standard by which to compare results, for it is largely dependent on conditions beyond the control of the turbine builder. For instance, if the plant does not contain superheaters, the B.t.u. per kilowatt-hour will be high. The same will be true of a plant which has a warm cooling-water supply for condensers and consequently carries low vacuum. Yet the turbines may be designed to give a high efficiency ratio under these conditions. In fact, they may be able to utilize the heat available more efficiently than the turbines in another plant with both high superheat and high vacuum.

This can be seen in the accompanying tabulation of recent turbine results. The Brown-Boveri turbine at the Dunstan power plant uses 14,980 B.t.u. per kilowatt-hour with an efficiency ratio of 68.8 per cent. Yet the Westinghouse City Electric, with a lower steam pressure, superheat and vacuum,

has an efficiency ratio of 68.9 per cent., though using 16,925 B.t.u. per kilowatt-hour. The Erste Brünner Vienna turbine requires 16,460 B.t.u. per kilowatt-hour with 71.8 per cent. efficiency ratio. It is therefore apparent that the efficiency ratio alone will express in the best manner the degree to which the designer has approached ideal results in his turbine.

The test results in the table were grouped in order to analyze the relative merits of the different types of turbines on the basis of efficiency ratios. The Curtis-Parsons machines built by Erste Brünner hold first place in the list, but are followed closely by others of the same type built by Brown-Boveri and Westinghouse Machine Co. The Parsons turbines built by Allis-Chalmers and Brown-Boveri also show high efficiencies. The second class in the order of efficiency includes turbines of the Curtis-Rateau and Curtis-Zoelly types, among which the turbines of the A. E. G. and British Westinghouse Co. show remarkably good results. The next group includes simple Zoelly and Rateau turbines. The last group comprises straight Curtis types.

The parsons low-pressure sections evidently utilize the heat in the steam only slightly more efficiently than do the impulse turbines. The great surface areas of all disk-type turbines which must be whirled in steam, produce losses which are apparently somewhat larger than the combined whirling losses and leakage in the Parsons drum turbines. Both the Zoelly and Curtis-Rateau types appear to use the steam more effectively in the low-pressure sections than the Curtis alone. Many European engineers hold the opinion that where high economy is to be obtained, the impulse turbine of the Rateau or Zoelly type is superior to the Curtis, though its manufacturing costs are higher. The Curtis-Rateau construction has all the commendable features of impulse turbines and has proved very economical.

The results in the table are from the best reliable tests that have been made on each type. Objections may be raised that these results do not represent actual operating condition as under varying loads, nor the average economy of any type of turbine. For instance, the Curtis turbine usually gives a very flat water-rate curve, while the Parsons type is more convex.

It is interesting to note that the best results have been obtained within the past two years and that these show a considerable increase in efficiency over the earlier turbines.

ENGINEERS' LIBRARY

Any book reviewed in these columns may be obtained through the Book Department of The Canadian Engineer.

BOOK REVIEWS.

Concrete Costs. By Frederick W. Taylor and Sanford E. Thompson. Published by John Wiley and Sons. Canadian agents, Renouf & Co., Montreal. Cloth, size 5 x 8 in., 82 figures, 709 pages. Price $5.00 net.

This is the first attempt that has been made to present in book form a thorough and minute analysis of the times required for performing every separate operation in concrete construction, and the cost of all these operations each by itself, as shown by the cost records of a great number of jobs taken from the records of many large contractors. The authors, Frederick W. Taylor and Sanford E. Thompson, have been engaged for some seventeen years past in a study of the building trades with the idea of applying to these trades the methods of time study and scientific management which have been so notably successful in factories. It was thought at the outset that this investigation could be made in a comparatively short time, but the difficulties of making accurate time studies of men engaged in the numerous tasks of concrete construction proved to be very great. The active work of time study was carried out by Mr. Thompson and his assistants under the advice of Mr. Taylor, and the investigation already completed covers some half dozen of the building trades.

"Concrete Costs" is believed by the authors to be of special value to (1) architects, engineers and contractors in making accurate estimates of the costs of concrete works and structures; (2) contractors, superintendents and foremen, to help them to lay out and plan their work in such a way that their materials will be more economically handled and used than in the past, so that each workman shall do more and better work than heretofore; and (3 to assist in introducing the principles of scientific management in the building trades.

The distinctive feature of this book is that the information given in its tables, curves, etc., as to how long workmen, machines, and teams ought to take to do all kinds of tasks, has been done by careful timing with the stop watch of all these tasks as they were being done in the course of the day's work. Heretofore, the best knowledge of the time required to do work of this character has been obtained by keeping records of the pay, and sometimes of the time of gangs or groups of workmen while they were doing whole jobs of work, or at best, quite large sections of the contract. Such figures, however, because of the fact that no two contracting jobs are exactly alike has made it impossible for the contractor to make much better than a good guess of the cost of his next job.

Tested by the actual cost figures of various jobs, as shown by the contractors' records, the tables of this book have proved themselves very accurate, since the cost as estimated from the tables has agreed very closely with the costs of the actual work as carried out under the most efficient contractors' systems.

Chapters I. and II. of the book present and analyze as a guide for very rough estimates the approximate costs of miscellaneous concrete work as given in technical publications. Curves showing the approximate costs of reinforced concrete buildings of specified dimensions from one to six stories in height, are given in Chapter III. The next two chapters include the first of the unique contributions of the book in an account of the applications of the principles of scientific management to construction operation. Succeeding chapters treat of the proportioning of concrete: The labor costs of excavating, crushing and transporting materials, and mixing of concrete by hand and machine; management, including illustrations of plant equipment and layout on many actual jobs. Three chapters are given to the subject of forms, both for mass concrete, for arches, and for a wide range of reinforced concrete buildings. A great number of detailed tables present the cost of every element, of every operation in construction work under stated conditions, and with directions on the same page as the table for adapting each particular table to certain variations of wages and other conditions. Probably not all readers will agree with all of it, but a careful study of the book will probably convince everyone that it is the most important book on concrete that has appeared on this side of the water.

Design of Electrical Machinery. Vol. I. Direct Current Dynamos. By William T. Ryan, E.E., assistant professor of Electrical Engineering, University of Minnesota. New York, John Wiley & Sons; London, Chapman & Hall, Limited; Montreal, Renouf Publishing Co. Price $1.50 net.

"A Manual for the Use Primarily, of Students in Electrical Engineering Courses." Two subsequent volumes are to treat of alternating current generators, synchronous motors, rotary converters, and transformers.

A theoretically sound and practical work whose worth is enhanced by the author's sensible recognition that it is not the function of a college course to develop full-fledged commercial designers. The treatment presupposes the knowledge—or at least the simultaneous study—of the fundamental scientific principles involved, and confines itself to the presentation and illustration of a logical and well arranged method of practically applying such principles to specific problems of design. There are many practical tables and empirical formulae exemplifying modern commercial practice and the recommended procedure is such as should enable anyone with the requisite knowledge of fundamentals to produce successful operating designs. The author makes no claim to have furnished a substitute for the experience and special knowledge without which commercially successful designs are not to be expected. As a manual for beginners within or without the class room the volume should be extremely useful.—J.A.J.

Superheated Steam in Locomotive Service. (An abstract of publication No. 127 of the Carnegie Institution of Washington) by W. F. M. Goss, has just been issued as Bulletin No. 57 of the Engineering Experiment Station of the University of Illinois. Price 40 cents.

This bulletin gives a summary of foreign practice in the use of superheated steam; it contains a report of an elaborate series of tests made upon an American locomotive to determine the precise advantage to be derived from superheating under various conditions of locomotive service; and it shows that the use of superheated steam is not attended by serious difficulties. The superheater is easily maintained,

and its presence as a detail of locomotive mechanism introduces no new problems in maintenance. The superheater improves the efficiency of the locomotive through the saving of coal and water. Tests run with boiler pressures varying from 120 to 240 lb. per sq. in., for which the steam was superheated approximately 150° F., prove that neither the steam nor the coal consumption is materially affected by considerable changes in boiler pressure. This fact justifies the use of comparatively low pressures in connection with superheating. The saving in water consumption was found to vary from 18 per cent. at a boiler pressure of 120 lb. to 9 per cent. at a boiler pressure of 240 lb., the corresponding saving in coal varying from 17 per cent. to 6 per cent. between pressures of 120 and 240 lb. The power capacity of the superheating locomotive was found to be greater than that of a saturated steam locomotive of the same general dimensions.

A New Analysis of the Cylinder Performance of Reciprocating Engines. By J. Paul Clayton, has just been issued as Bulletin No. 58 of the Engineering Experiment Station of the University of Illinois.

The uses of the steam engine indicator have hitherto been limited to rather simple processes such as that of determining the indicated horse-power of an engine, or to that of settling valves. The investigation described in this bulletin discloses the fact that the indicator diagram constitutes sufficient evidence upon which to base an analysis of cylinder performance, the results of which have not heretofore been considered possible. The process involves the transferring of the indicator diagram to logarithmic cross-section paper, and the drawing of a figure called a logarithmic diagram. By the aid of this diagram, it has been found that the expansion and compression of all elastic media used in practice obey substantially the polytropic law $P V^n = C$. From this fact there have been developed rational methods of approximating the clearance of a cylinder, of closely locating the cyclic events, and of detecting moderate leakage with the engine in normal operation.

It has been discovered that the value of n in the law $P V^n = C$ is controlled directly in steam cylinders by the quality of the steam in the cylinders at cut-off, and that this relation of the value of n and the quality is practically independent of cylinder size and of engine speed for the same class of engine. From this fact there has been devised a method of computing the actual steam consumption of an engine from the indicator card alone, to within 4 per cent. of the consumption as measured by test.

Copies of Bulletin No. 58 may be obtained upon application to W. F. M. Goss, director of the Engineering Experimental Station, University of Illinois, Urbana, Illinois.

Bulletin No. 24, "The Economy Steam Turbine for Belt Drive," has just been published by the Kerr Turbine Co., Wellsville, N.Y. This bulletin shows belted economy turbine installations.

Note.—The book reviews will be continued in next week's issue.

NEW GOVERNMENT BUILDING.

The new government building at the Canadian National Exhibition is being rushed to completion and will be ready for the year's Fair. It will cost $160,000, of which the Dominion Government pays $100,000, the Ontario Government $25,000 and the city of Toronto the balance. It will be used for Provincial, Dominion and educational exhibits.

VALUE OF FOREST PRODUCTION.

The total value, at the point of production, of the annual forest products of Canada is at least $166,000,000. This is $22.44 for every person in Canada, March 31, 1909. In 1909, there were cut from Canadian forests about 400 cubic feet of timber for every inhabitant of the country. This is a per capita timber usage unequalled by that of any of the other important countries in the world.

CANADIAN ELECTRICAL ASSOCIATION.

The members of the above association held their twenty-second annual meeting in the city of Ottawa, June 19th, 20th and 21st last.

The members of the association were welcomed on behalf of the city by Controller Hinchey, acting mayor. The titles of the papers and those who delivered them were: "Recent Developments in Lamps and Reflectors," by J. G. Henninger, illuminating engineer, National Electric Lamp Association; "The Influence of Ice on Water Power Development," by Professor H. T. Barnes, D.Sc., F.R.S., McGill University, and "Distributing Systems for Outlying Districts and Smaller Points," by S. Bingham Hood, Toronto Electric Light Company. On each of the papers an interesting discussion took place, and in particular on that of Professor H. T. Barnes, Mr. J. Murphy, electrical engineer of the Department of Railways and Canals, showing a number of fine slides illustrative of the ice difficulty.

In the evening the delegates to the convention and their friends to the number of several hundred journeyed out of the Victoria Hotel at Aylmer, where they were the guests of the city at an informal dance and garden party.

Mr. Pack, of the Toronto Electric Light Company, was elected president, and Mr. T. S. Young is the honorary secretary.

PERSONAL.

MR. C. D. CAMPBELL has been appointed town engineer, of Galt, Ont., succeeding Engineer Fuce, who is going to Calgary to open a private office.

MR. F. S. HAM, of the firm of Ham, Baker and Company, Limited, London, England, visited Toronto last week. Mr. Ham is in Canada on a business trip.

DR. A. A. WEAGANT, Ottawa; DR. THOS. E. KAISER, Oshawa, and DR. HENRY R. CASGRAIN, Windsor, have been appointed to the Provincial Board of Health of the Province of Ontario.

MR. BION J. ARNOLD, Chicago, and MR. J. M. MOYES, Toronto, have been engaged by Corporation Counsel Drayton and Mayor Geary as traffic experts to report on a comprehensive street railway system for the city of Toronto.

MR. H. G. BURD, who for some time has been connected with the Standard Underground Cable Co., as sales engineer in the New York office, has been appointed assistant to the sales manager of the Standard Underground Cable Co., of Canada, Limited, with headquarters at Hamilton, Ont.

MR. WILLIAM H. MARSH, who for the past ten years has been connected with the Standard Underground Cable Co., of Pittsburg, Pa., in the capacity of superintendent of construction, has been appointed secretary and assistant treasurer and sales manager of the Standard Underground Cable Co., of Canada, Limited, with headquarters at Hamilton, Ont.

OBITUARY.

CAPTAIN KILLALY GAMBLE, R.A., late secretary-treasurer of the Association of Ontario Land Surveyors, is dead. His death occurred at Bournemouth, England.

He was born at Enniskillen, Ireland, educated at Portora school, and entered as a cadet at Woolwich, where he took a high stand. During his military career he served on duty at Dublin, Malta, Gibraltar, Halifax, Bermuda, and other British garrisons.

Invalided after sixteen years, he retired from the service and came to Canada in 1882. He then entered the profession of land surveying at Winnipeg, and later, having received commissions as Dominion Land Surveyor and Provincial Land Surveyor for Ontario, became established in Toronto. In 1886 Captain Gamble married Miss M. d'A. Killaly, youngest daughter of the late Hon. H. H. Killaly, and was predeceased by her two years.

During the year 1911 Mr. Gamble was president of the Engineers' Club of Toronto, and had many warm personal friends, not only in the city, but throughout the province and in the old land.

COMING MEETINGS.

SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION.—June 26th-28th. Annual meeting at Boston, Mass. Sec'y, H. H. Norris, Cornell University, Ithaca, N.Y.

THE UNION OF CANADIAN MUNICIPALITIES.—August 27, 28 and 29. Meeting at City Hall, Windsor, Ont. Hon. Secretary-Treasurer, W. D. Lighthall, K.C.

CANADIAN FORESTRY ASSOCIATION.—Convention will be held in Victoria, B.C., Sept. 4th-6th. Secy., James Lawler, Canadian Building, Ottawa.

CANADIAN PUBLIC HEALTH ASSOCIATION.—Second Annual Meeting to be held in Toronto, Sept. 16, 17 and 18.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Annual Assembly will be held at Ottawa, in the Public Library, on 7th October, 1912. Hon. Sec'y, Alcide Chaussé, 5 Beaver Hall Square, Montreal, Que.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE: Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—177 Sparks St. Ottawa. Chairman, S. J. Chapleau, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving; Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, C. E. Cartwright; Secretary, W. Alan, Kennedy; Headquarters: McGill University College, Vancouver.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1290.

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydonejack; Meets every first and third Friday of each month, October to April, in University of Manitoba, Winnipeg.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton; Secretary-Treasurer, Mr. K W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm. Mason, Bon Accord, Alta. · Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, W. Sanford Evans, Mayor of Winnipeg; Hon. Secretary-Treasurer, W. D. Lighthall, K.C., Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, Mayor Mitchell, Calgary.; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALTIES.—President, Reeve Forke Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewit, General Manager Consumers' Gas Company, Toronto; J. Keillor, Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President, J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary. H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Jas. Anderson, Gen. Mgr., Sandwich, Windsor and Amherst Railway; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, Killaly Gamble, 703 Temple Building, Toronto.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, J. E. Ganier, No. 5. Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, F. S. Baker, F.R.I.B.A., Toronto, Ont.; Hon. Secretary, Alcide Chausse, No. 5. Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman; Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, J. P. McRae; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Wm. Pierce, Calgary; Secretary-Treasurer, John T. Hall, Brandon, Man.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, 115 Phœnix Block, Winnipeg, Man. Second Monday, except June, July and August, at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc.
Printed forms for the purpose will be furnished upon application.

PLANS AND SPECIFICATIONS ON FILE.

The following Plans (P.) and Specifications (S.) are on file for reference only unless otherwise noted at the office of The Canadian Engineer, 62 Church Street, Toronto:—

Bids close	Noted in issue of
7-3—Storm Drain, Orillia, Ont.	P. & S. 6-27
7-1—Boilers, pumps, Verdun, Que.	(S.) 6-27
7-15 Supply of electrical machinery and sewage disposal works, Battleford, Sask. .....(P. & S.) 6-27	
(Earlier plans and specifications are also on file at The Canadian Engineer Offices, Montreal and Winnipeg.)	

TENDERS PENDING.

In Addition to Those in this Issue.

Further information may be had from the issues of The Canadian Engineer referred to.

TENDERS.

Arthur, Ont.—Tenders will be received by Mr. D Brocklebank up to noon of June 28th for the construction o five reinforced concrete girder bridges for the County o Wellington, near Arthur. Plans, etc., at the office of Messrs Bowman and Connor, engineers, 36 Toronto Street, Toronto

Battleford, Sask.—Tenders will be received by J. P Marshall, secretary-treasurer of the town of Battleford, Sask, until noon of July 10th, 1912, for the supply and delivery o machinery and materials for the erection of generators, ex citers and switchboard, pumps and motors, power house an reservoir, sewage disposal works, supply and delivery of stee water pipe and specials, trenching and laying steel wate pipe, etc., two pneumatic storage tanks. Plans and specific ations may be seen at the offices of The Canadian Engineer [illegible]nipeg, Toronto and Montreal, at the office of the Battle ford town engineer and electrical engineer, and at the offic of Messrs. McArthur, Murphy and Underwood, consultin engineers, Bottomley Block, Saskatoon. (See advt. in Cana dian Engineer.)

Carleton Place. — The Sewers and Water Commissio will receive tenders up to noon of July 9th, 1912, for the sup ply of all materials and construction of about five miles o sewers, and five miles of water mains. Plans and specifica tions may be seen at the offices of the consulting engineer Toronto, or the office of B. G. Michel, Carleton Place, Ont T. Aird Murray, 303 Lumsden Building, Toronto, consult ing engineer. (See advt. in Canadian Engineer.)

Estevan, Sask.—Tenders will be received until July 9th 1912, for the construction of the following works:—

Contract "A"—Water works force main.
" "B"—Water works pump house.
" "D"—Water pipes.
" "G"—Pumping machinery.
" "[illegible]"—Pump well.
" "O"—Outfall sewer.
" "X"—Sewage disposal works.

Plans and specifications may be seen at Estevan, or at th engineer's offices. L. A. Duncan, Esq., secretary-treasure Estevan; Chipman and Powers, engineers, Toronto an Winnipeg.

Estevan, Sask.—Tenders will be received by H. N Scott, Esq., secretary-treasurer, High School Board, up t noon of July 10th, 1912. Plans and specifications may b seen at the office of Storey and Van Egmond, Architects Regina, Sask., and at the office of the Secretary-Treasurer.

Guelph, Ont.—Tenders for the construction of a 70 x 1 ft. steel bridge at Rockwood, concrete abutments for same and for a reinforced girder bridge near Elora, will be re ceived by J. W. Sutton, Esq., Court House, Guelph, unt June 29th, 1912.

Guelph, Ont.—Tenders will be received until July 5th 1912, for the following works:—

1. Concrete work on a combined bridge and dam on th River Credit, at the paper mills, Georgetown.
2. For the steel beam superstructure of the abov bridge.
3. For the concrete abutments and floor for a steel high way bridge, 100-ft. span, over the River Credit, on the 10t line, Esquesing Township.

4. For the steel superstructure of the above bridge.

5. For the construction of a concrete abutment under Capias Bridge in Glen Williams.

Plans and specifications at the Paper Mills, Georgetown, at the office of Mr. Moore, Reeve of Georgetown, or at the office of Malcolm and Rudd, Metropolitan Bank Building, Guelph. J. Hutcheon, Engineer, Guelph. (See advt in The Canadian Engineer.)

High River, Alta.—Tenders will be received by Geo. E. Mack, Esq., secretary-treasurer, High River, until July 16th, 1912, for the following works:—

Contract "B"—Pump house.
" "G"—Pumping machinery.
" "I"—Pump well.
" "P"—Ejector station.
" "X"—Sewage disposal works.

Plans and specifications may be seen at High River or at the offices of Messrs. Chipman and Powers, engineers, Toronto and Winnipeg, after June 29th.

Kindersley, Sask.—Tenders will be received until July 22nd, 1912, for the supply and delivery of waterworks and electric light equipment. Specifications, etc., at the office of the Engineers, The John Galt Engineering Company, 317 Portage Avenue, Winnipeg. D. MacTavish, Secretary-Treasurer, Kindersley. (See advt. in The Canadian Engineer.)

Kingston, Ont.—The Government will call for tenders shortly for the construction of the temporary bridge over the Cataraqui River, to take the place of the present structure until such time as the new bridge is completed.

Moose Jaw, Sask.—Tenders will be received until noon of July 10th, 1912, for water gates for high pressure distribution pipes. Plans, etc., may be obtained at the office of the City Commissioners, Moose Jaw, where tenders will be received.

North Battleford, Sask.—Tenders for the construction of a pump well will be received by H. W. Dixon, Esq., secretary-treasurer, until July 2nd, 1912. Plans and specifications may be seen at North Battleford, or at the office of the engineers, Messrs. Chipman and Powers, Toronto and Winnipeg.

North Toronto, Ont.—Mr. F. How, Chairman Board of Works, will receive tenders up to noon, Tuesday, July 30th, 1912, for the construction of pavements and storm sewers. (See advt. in this week's issue The Canadian Engineer.)

Ottawa, Ont.—Tenders will be received until July 4th, 1912, for the construction of a wharf at Needles, B.C. Plans, etc., at the offices of R. C. Desrochers, Secretary, Department of Public Works, Ottawa.; C. C. Worsfold, district engineer, New Westminster, B.C.; postmasters at Needles and Victoria, B.C.

Ottawa, Ont.—The Department of Public Works will receive tenders until July 2, 1912, for dredging required at St. George, N.B. Full particulars may be obtained from the Secretary, Department of Public Works.

Ottawa, Ont.—The Department of Militia and Defence will receive tenders up to noon of July 10, 1912, for the construction of a rifle range at St. Catharines, Ont. Full particulars at the offices of the officer commanding the 2nd Division, Toronto, Ont.; Lt.-Col. W. W. Burleigh, O.C. 19th Regiment, St. Catharines; and the Director of Engineer Services, headquarters, Ottawa.

Prince Albert, Sask.—Tenders for sewage pumps will be received by the City Commissioners up to noon of July 12th, 1912. Specifications and plans may be obtained at the office of the City Engineer. C. O. Davidson, city clerk. (See advertisement in The Canadian Engineer.)

Peterborough, Ont.—Tenders will be received until June 27 for the erection of a fire-proof addition to the Nicholls Hospital. Also a laundry building. Plans and specifications can be seen at the office of W. Blackwell, architect, Water Street. John Crane, secretary.

Port Hope, Ont.—Mr. Henry White, secretary Library Board, will receive tenders up to noon of July 5th for the several trades in connection with the erection of a library. Plans and specifications at the library building, Port Hope, or at the office of W. A. Mahoney, architect, Telephone Building, Guelph, Ont.

Regina, Sask.—Tenders for the trenching and laying of sewer mains on certain streets in the city will be received by the City Commissioners until June 27, 1912. Plans, etc., at the office of the City Engineer. L. A. Thornton, City Commissioner.

St. Charles, Man.—Tenders will be received until July 6th, for the construction of a trunk sewer on Ferry Road. Plans, and specifications, with full information may be obtained at the office of the Municipal Engineer, Municipal Hall, St. Charles. Frank Ness, Treasurer, Kirkfield Park P.O., Man.

St. John, N.B.—The city of St. John invites tenders for the following works, viz.: Excavation, backfill and cartage for water main in Milford Road; excavation, backfill and cartage for main sewer in St. John Street West. Plans, etc., at the office of the City Engineer, No. 5, City Hall. Rupert Wigmore, Commissioner of Water and Sewage.

Stratford, Ont.—The Board of Works intend to call for tenders immediately for the Remeo Creek scheme.

Toronto, Ont.—Tenders will be received until noon of July 4th, 1912, by W. W. Scott, Esq., township clerk, Moorefield, for the construction of a steel bridge of 110 ft. span over the Connestogo River, also for concrete abutments for the same. Plans and specifications at the office of the clerk or Bowman and Connor, engineers, 36 Toronto Street, Toronto.

Watrous, Sask.—Tenders will be received by Joseph Gaye, secretary-treasurer, of the town of Watrous, for the following works:—

Contract A—All labor and certain materials necessary for the laying water pipes and sewers.

Contract B—All labor and materials necessary for the construction of pump house.

Contract C—This contract will be subdivided as follows:—

1—Furnishing materials and labor for and erecting steel water tower.

2—Furnishing materials and labor for and constructing concrete foundation for water tower.

3—Furnishing material and labor for and constructing frame housing for water tower.

Contract D—Furnishing cast-iron water and special castings.

Contract E—Furnishing gate valves, fire hydrants, etc.

Contract G—Furnishing and erecting pumping machinery.

Contract I—Furnishing material for and constructing collecting galleries and suction well.

Contract S—Furnishing sewer pipes and junctions.

Contract T—Furnishing labor and material for concrete walks.

Tenders will be received until July 15th, 1912, for Contracts A, C, D, E, S and T, and until July 31st, for Contracts B, G, and I.

Plans, etc., may be seen at the Town Hall, Watrous, or at the Engineers' Offices, Winnipeg and Toronto, on or after July 1st. Messrs. Chipman and Powers, engineers.

Weston, Ont.—The Municipal Council of the Village of Weston will receive tenders up to noon of July 8th, 1912, for the supply of all materials and the construction of sewerage and storm water drainage. Plans and specifications at the office of T. Aird Murray, consulting engineer, 303 Lumsden Building, Toronto. J. H. Taylor, clerk, Weston. (See advt. in Canadian Engineer.)

Winnipeg, Man.—Tenders will be received by the Chairman, Board of Control, until July 15th, 1912, for the supply for a quantity of 12-inch cast-iron water pipe and specials, hydrants and gate valves for extension of the fire service waterworks. Specifications, etc., at the office of the City Engineer, 223 James Avenue. M. Peterson, Chairman, Board of Control Office, Winnipeg.

CONTRACTS AWARDED.

Charlottetown, P.E.I.—Messrs. Clark and Morrison have received the contract for the erection of a railway station to cost $30,000 for the Federal Government, Ottawa

Dartmouth, N.S.—Messrs. F. A. Ronnan and Co., of Halifax, have the contract for the erection of a three-story brick and stone hospital to cost $80,000. Mr. Herbert E. Gates, architect, Telephone Building, Halifax, N.S.

Moose Jaw, Sask.—The Canada Foundry Company, Winnipeg, have been awarded the contract to supply a number of hydrants for the municipality. Messrs. Drummond,

Tarvia

Preserves Roads
Prevents Dust~

Tarvia Modern Pavement in Mount Pleasant Cemetery, Toronto.

Why this Cemetery Wants More Tarvia.

IN 1909, Mount Pleasant Cemetery, Toronto, built some beautiful roads with "Tarvia X," according to our Modern Pavement Specification. Cemetery roads get hard use from the heavy loads incident to the transportation of monuments, and ordinary macadam fails under such crushing strains. The tarviated macadam, being slightly plastic, is improved by such rolling.

Ordinary macadam is not clean enough for pedestrian processions in cemeteries, but a tarviated surface produces no dust or mud and is clean and firm immediately after a rain, shedding water as promptly as a good tar sidewalk.

Tarvia also reduces maintenance expenses, because it wears better than plain macadam under traffic and resists water action on grades.

After three years' trial of Tarvia, the cemetery authorities are paying it the truest kind of testimonial, namely, a repeat order, as per the following letter:—

Toronto, Ont.

Dear Sirs:

I wish to let you know we will require "Tarvia X" to build about 6500 yds. of road this year, about the end of July.

I may say that we are well pleased with our Tarvia roads. The first that were made in 1909 have stood the test of traffic and heavy loads up to 16 tons—the wagon wheels leaving no impression.

Where our roads have a 7% grade we find the Tarvia fills the bill; no washing, no dust, easy to sweep and clean in wet weather.

(Signed) W. H. FOORD, Supt.

Tarvia is made in three grades:

"Tarvia X" for use in constructing roads and pavements.

"Tarvia A" for hot surface applications.

"Tarvia B" (applied cold) for dust prevention and road preservation.

Booklets regarding Tarvia will be sent free on request.

The Paterson Manufacturing Co., Limited
MONTREAL TORONTO WINNIPEG VANCOUVER

The Carritte-Paterson Manufacturing Co., Limited
ST. JOHN, N.B. HALIFAX, N.S.

McCall Company of Montreal will supply a number of valves.

Newmarket, Ont.—Mr. J. J. McIntosh, of Alexandria, Ontario, has been awarded the contract for the erection of a Public school at a price of $21,760.

Toronto, Ont.—Messrs. Ross and MacFarlane, of Montreal, are the winners of the competition of the Board of Education for suitable plans for the new technical high school. Messrs. Brown and Vallance, of Montreal, and C. S. Cobb, of Toronto, came second and third respectively.

Toronto, Ont.—Messrs. Deaks and Hinds, of the Toronto Construction Company, have been awarded the contract for the proposed double-tracking of the C.P.R. between Sudbury and Port Arthur. Ten million dollars is the estimated cost of construction.

Toronto, Ont.—The National Iron Works, Toronto, has applied for a permit from the City Architect for alterations and additions to the pipe foundry on Cherry Street. The building is to be of concrete and steel and will cost $50,000. Mr. Gordon F. Perry is general manager.

Toronto, Ont.—Messrs. R. Weddell and Company, of Trenton, Ontario, have been awarded a contract calling for dredging in the harbor of this city.

Vancouver, B.C.—Mr. W. H. Rourke, Vancouver, has received the contract for the construction of the new lighthouse tower to be constructed at Point Atkinson. The structure will be of concrete and about forty-five feet high. Total cost will be about $15,000.

Vancouver, B.C.—Mr. Wm. O'Dell has the contract for the erection of a six story brick building for the Vancouver Realty Company. The cost of the building will be approximately $40,000.

Western Ontario.—Messrs. Deeks and Hinds, of Toronto, have received a contract from the Canadian Pacific Railway to double track the line for sixty miles between Sudbury and Port Arthur.

Winnipeg, Man. — The Provincial Government have awarded the contract for the construction of the new law courts to the National Construction Company. The amount of the tender was $760,000.

RAILWAYS—STEAM AND ELECTRIC.

Kingston, Ont.—The Grand Trunk Pacific Railway has placed an order with the Canadian Locomotive Works for 15 locomotives.

Niagara District, Ont.—A report states that the Niagara, Welland and Lake Erie Electric Railroad will construct and operate a new line between Welland and Port Colborne within the next few months. Mr. C. J. Laughlin is general manager of this company.

Ottawa, Ont.—The Board of Railway Commissioners have postponed a meeting called for July 2nd next to July 3rd.

At this meeting railway companies will be asked to show cause why a general order should not issue requiring railway companies to furnish a heated car service.

Toronto, Ont.—Both Queen Street and King Street subway are to be reconstructed within the next year by the Grand Trunk Railway.

Toronto, Ont.—The Ontario Railway Board has ordered the management of the Toronto Suburban Railway to rebuild their line on Bathurst Street and Davenport Road, and lay a pavement between the rails and eighteen inches on either side.

Western Canada.—A report emanating from Montreal states that there is a probability of the Canadian Pacific Railway electrifying their lines through the Rocky Mountains upon completion of the double track.

EXTENSION TO NATIONAL IRON WORKS.

The National Iron Works of Toronto, has received a permit for an extension to its pipe foundry. The extension will cost in the neighborhood of $250,000, the contract having been let to the Eastern Construction Company. With this enlargement the company will be in a better position to take care of the greatly increased orders for cast-iron pipe.

LIGHT, HEAT AND POWER.

Brantford, Ont.—Arbitration without any conditions attached whatever has been decided on between the city and Cataract Power Co., over local rates. The agreement between the city and the company will form the basis of the arbitration, the chief point to settle being whether hydro-electric municipalities are securing power and light at a lower rate than Brantford.

Edmonton, Alta.—The public works commissioners and the light, heat and power commissioners will confer on a report submitted by J. M. Brodie on the matter of a municipal gas plant. The report gives the two following alternatives, one of which makes a total of $700,000, which would provide for, in addition to the central generating station, 65½ miles of gas mains: 44 on the north side, and 21 on the south side. This amount would cover the expenditure for possibly four years. The other alternative was for a total of $465,485, which, in addition to the central generating station, would give 26 miles of distributing mains; 20 miles on the north side and 6 miles on the south side.

Kindersley, Sask.—The municipal council will install an electric light system. The John Galt Engineering Company, Winnipeg, Man., are interested in the scheme.

Lethbridge, Alta.—The financial statement of the municipal electric and street railway departments to the end of April is given as:

Month	Receipts.	Expenditures.
January	$10,733.82	$ 5,059.31
February	9,755.22	5,535.45
March	8,449.57	4,279.35
April	8,614.07	3,819.61
	$37,552.68	$18,693.72

This leaves a profit of $18,858.96. Deducting $11,911.86 for interest and sinking fund, a net profit for the four months is left amounting to $6,947.10.

In the power house there has been generated 577,540 K.W.H. for the four months and 113,560,000 gallons of water pumped.

GARBAGE, SEWAGE AND WATER.

Winnipeg, Man.—The municipal engineering department are about to commence work on a system of high pressure water mains.

Kindersley, Sask.—The town council have decided to install a waterworks taking the supply from a dam located about a mile to the south of the municipality. The John Galt Engineering Company, Winnipeg, Man., are interested in the scheme.

BUILDINGS AND INDUSTRIAL WORKS.

Collingwood, Ont.—The Dominion Government will construct an efficient biological laboratory to be used in connection with the whitefish hatchery to be erected at an early date.

Edmonton, Alta.—Plans and specifications are now being prepared by Messrs. Van Siclen and MacComber for a ten story hotel to be erected on Peace Ave. The cost of this structure will be about $350,000. Mr. E. W. Chambers is representing a syndicate that are supplying the capital for this enterprise.

Guelph, Ont.—There is a strong probability of the Dominion Casket Company locating a plant in this city.

Halifax, N.S.—A report states that the Canadian Pacific Railway will erect a large hotel in this city.

Hespeler, Ont.—The Dominion Government will erect a new post office at a cost of $10,000.

Medicine Hat, Alta.—A report states that the management of the Canada Cement Company are contemplating the erection of a million dollar plant in this city for the purpose of meeting the demands of Western Canada.

Montreal, P.Q.—The municipal council will erect one public lavatory on Jacques Cartier Square, and if the same proves successful five or six more will be constructed.

Mr[illegible]al, P.Q.—A report states that the Canadian Northern Railway, by reason of recent purchases, intend to make extensions to the Moreau Street Station. The yards at this point will be enlarged to twice their present capacity.

Moose Jaw, Sask.—There is a probability of a new immigration hall being erected in this city.

Port Colborne, Ont.—Work has started on the new plant of the Canadian Union Furnace Company.

Regina, Sask.—Messrs. Storey and Van Egmond have prepared plans for a new steam laundry to be erected for Messrs. Whitmore Bros. The building will be 50 x 100 feet of brick and steel construction, 3 stories, and the cost will be about $100,000.

St. Catharines, Ont.—The damage to the Welland Canal by reason of the recent accident will amount to $7,000.

Toronto, Ont.—The management of the Adams Harness Manufacturing Company have purchased a site on Logan Avenue, and on the same will erect a factory for the manufacture of blankets and horse collars.

Vancouver, B.C.—Mr. A. G. Ferra, Italian Consul, will erect a six story apartment house on Hastings Street. It will be of brick and terra cotta 50 x 122 feet. Mr. F. H. Perkins, of Vancouver, B.C., is the architect.

Vancouver, B.C.—Mr. W. McPherson is erecting a four story mill construction warehouse 100 x 50 feet. Messrs. Townsend and Townsend are the designers.

Victoria, B.C.—Mr. Jesse M. Warren has prepared plans for a church building to be erected by the congregation of the First Baptist Church. The materials are pressed brick and cut stone. The structure will cost about $100,000.

BRIDGES, ROADS AND PAVEMENTS.

Dauphin, Man.—The engineering department of this municipality will shortly call tenders for the superstructures of eight bridges. Mr. J. A. Gorby is secretary-treasurer of this town.

Hull, P.Q.—The City Engineer, J. P. A. Laforest, is preparing plans for a concrete bridge to replace the present structure at the pump house. The bridge will have a length of fifty feet and will cost about $1,500. If the plans are approved by the council the work will be commenced this season.

Irishtown, N.B.—The provincial Public Works Department will erect a new concrete bridge and undertake considerable road work in this section.

Lindsay, Ont.—The municipal council will call tenders for cement sidewalks.

Listowel, Ont.—The municipal council are considering the matter of street paving, and it is probable that tenders will be called in the near future. W. Climie is mayor of this town.

St. Catharines, Ont.—The municipal council have decided to construct a concrete bridge, 800 feet in length, across the old canal. The cost of this work will be $65,000. R. D. Brown, City Engineer.

St. Catharines, Ont.—Property owners in the vicinity of St. Paul Street will petition the municipal council to have a bridge constructed across Lock No. 3 of the Welland Canal.

Toronto-Hamilton, Ont. — A committee composed of W. A. MacLean, E. A. James, A. F. McCallum, W. D. Platt and Mayor T. L. Kennedy, president of the Good Roads Association, will secure information as to the best class of pavement and the probable cost of constructing a permanent highway between these two cities.

York County, Ont.—The County Council have adopted a by-law to raise $50,000 for the continuance of the bridge building programme.

FIRES.

Canning, N.S.—The business section of this town was sadly damaged by fire. The loss is estimated at $100,000.

CURRENT NEWS.

Montreal, P.Q.—A section of the pavement on Sherbrooke Street gave way beneath a steam roller weighing twelve tons engulfing the machine to a considerable depth. This is the third time that a similar accident has happened on this street, an automobile and a steam wagon being in the former mishaps.

North Toronto.—Mr. E. A. James, engineer of this municipality, has prepared the following estimates as a guide to the ratepayers voting on the question of double tracking the lines of the Metropolitan Railway:—Storm sewer, $25,000; curbing both sides, $14,520; paving, $155,200; special foundation under rails, $72,000; total, $266,720.

Toronto, Ont.—At the meeting of the Ontario Municipal Association which met in this city last week, Mayor George H. Lees, of Hamilton, was elected president of the association. Other officers were elected as follows: Vice-presidents, J. G. Richter, London; W. A. Clarke, York Township; Mayor G. J. Thorp, Guelph; R. C. Chown, Belleville; and W. Lane, Goderich; secretary-treasurer, K. W. McKay, St. Thomas; Executive Committee, Mayor Geary, Toronto; Mayor Lemon, Owen Sound; W. B. Doherty, St. Thomas; City Solicitor Wm. Johnstone, Toronto; F. R. Waddell, K.C., Hamilton; J. H. Dewey, Brockville; A. K. Bunnell, Brantford; Dr. Fairbank, Petrolea; S. Baker, London; S. R. Armstrong, Peterboro; S. H. Kent, Hamilton, and W. C. Campbell, St. Thomas.

TRADE ENQUIRIES.

The following were among the inquiries relating to Canadian trade received at the office of the High Commissioner for Canada, 17 Victoria Street, London, S.W., during the week ending June 10th, 1912:—

A Manchester firm of printing, stationery and advertising contractors are desirous of acting for Canadian firms who may wish to open business in Great Britain.

An Australian merchant house at present importing large quantities of United States goods of various descriptions, is prepared to do business with Canadian manufacturers.

A London correspondent desires to obtain agencies for the sale of Canadian goods.

A London firm make inquiry for the names of Canadian manufacturers of baking powder open to import supplies of tartaric acid, cream of tartar and citric acid.

A German firm interested in a patent potato digging machine desire to appoint reliable Canadian agents.

From the branch for city trade inquiries, 73 Basinghall Street, E.C.:—

A London company manufacturing athletic goods, and also leather travelling bags and trunks, and similar lines are desirous of finding a resident Canadian representative to act for them upon a commission basis.

CANADIAN NORTHERN RAILWAY WORK FOR 1912.

The following is an itemized list of the principal works on the construction programme of the Canadian Northern Railway:

Number of miles to be started this year, 1,053 miles.

Location of lines in actual construction this year:

Montreal to Hawkesbury, 58 miles.

Ottawa to Ottawa River, 32 miles.

West from Ruel, Ont., 100 miles.

East from Port Arthur, 108 miles.

Branch lines, and extensions in Alberta and Saskatchewan, 400 miles.

British Columbia, 75 miles.

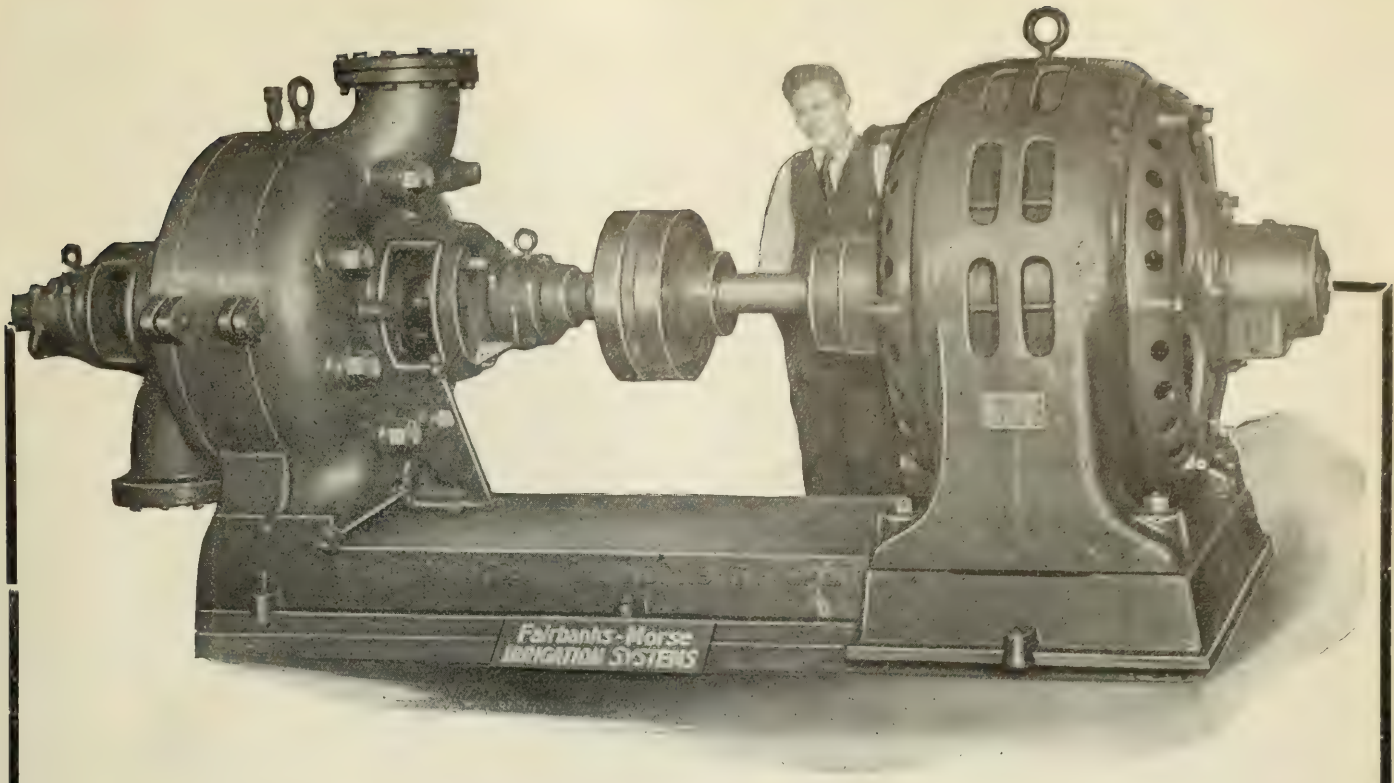
Sydenham, Ont., to Ottawa, 80 miles.

Relaying track on main line west, 200 miles.

Approximate number of men employed on construction, about 20,000.

Approximate amount of steel required for new tracks this year, 125,000,000 pounds.

Amount of new equipment to be installed this year, estimated cost, $8,000,000 to $9,000,000, including 136 engines, 4,050 box cars, 1,184 flat cars, 400 convertible construction cars, 70 cabooses, 6 snow plows, 1 rotary plow. 82 passenger cars, 35 mail and baggage cars, 3 dining cars, 4 parlor cars, 16 sleepers.



The Largest Direct Connected Centrifugal Pumping Unit in British Columbia.

The Vancouver Power Company have recently installed at their works at Coquitlam Dam, B.C., the largest direct connected centrifugal pumping unit in British Columbia. This outfit is to operate in parallel with a number of other pumps that are to furnish water under pressure for sluicing into place the material for their new dam.

This pump is a 10-inch, class "F," two-stage centrifugal, with bronze inpellers and renewable bronze diffusion vanes. It has a normal capacity of 1833 imperial gallons per minute when operating at 1160 r.p.m. against a total head of 355 feet or an equivalent pressure of 154 lbs. per square inch. It is mounted on a common sub-base with a 300 h.p. type "B," Fairbanks-Morse squirrel cage, induction motor, 2200 volts, 60-cycle, 3-phase, 1160 r.p.m. at full load, being direct connected thereto by means of a flexible leather link coupling

The motor possesses a feature in rotor construction that is unique. The end rings are welded on to the rotor bars by a new process, making a perfect joint, free from the troubles common to the purely mechanical or riveted joint, such as oxidation, working loose, and solder-throwing. This improvement marks a long step forward in the elimination of rotor trouble.

Our Vancouver Branch supplied and assembled this complete pumping unit. We are in a position to quote on the necessary equipment for any pumping requirements on receipt of specifications.

BACK COPIES OF ENGINEER WANTED.

One copy of The Canadian Engineer of the following dates are required. The usual extension of the sender's subscription will apply in this case: April 4th, 1912; January 5th, 1911; March 23rd, 1911.

SILVER IN NEWFOUNDLAND.

A silver miner, lately returned to his home at North Shore, Cape Breton, from the west is said to be about to undertake the examination of what appears to be a valuable silver deposit in Newfoundland not far from the tide water. The shipping facilities are excellent and a river capable of yielding 4,000 horsepower for the generation of electricity for use in the mine milling of the ore and smelting on the ground is available on the property.

CEMENT IN WESTERN CANADA.

Up to the middle of June about 100,000 barrels of cement have been ordered from the United States from the province of Alberta.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from The Canadian Engineer for small fee.

16710—June 4—Approving revised rule relating to Baggage of Excess Size as follows:—"Commencing July 1st, 1912, for any piece of baggage of any class (except immigrant baggage checked at port of landing, and whips in canvas or leather cases), the greatest dimension of which exceeds forty-five inches, there will be an additional charge for each additional inch equal to the charge for five pounds of excess baggage."

16711—June 7—Authorizing G.T.R. to construct additional team tracks along and across Esplanade St., Toronto, Ont.

16712—June 8—Authorizing C.N.O. Ry. to cross public road on Lot 11, Range 2, Twp. of Clarendon, Ct. Pontiac, Que.

16713—June 8—Authorizing C.P.R. to open for carriage of traffic double track from mileage 92.4 to Carberry, Man., at mileage 105.7, Manitoba.

16714-15—June 6—16716—June 5—16717—June 7—Authorizing C.P.R. to construct spur for T. D. Robinson and Sons, Winnipeg, Man., for M. Rumely Company, Saskatoon, Sask., for International Harvester Co., Lethbridge, Alta., and for Three Rivers Harbor Commissioners, at Bureau Wharf, Three Rivers, Que.

16718—June 8—Authorizing C.P.R. to cross Saskatchewan Ave., Edmonton, Alta., by overhead bridge and across Hardisty Avenue, by grade crossing.

16719—June 1—Approving location of Lake Erie & Northern Ry. from Grand River to Colborne St., Brantford, Ontario.

16720—June 10—Approving change in location C.P.R. station at Vancouver, B.C.

16721—June 10—Authorizing C.N.O. Ry. to open for carriage of traffic its line from Trenton to Deseronto and rescinding Orders 15211 and 15940, Oct. 28, and Feb. 13th, 1912.

16722—June 14—Directing G.T.R. to re-locate loading siding east of Vineland Station, Ont., and to erect fruit shed.

16723—June 11—Approving location of Algoma Eastern Ry. Co. across Little Current Channel, between mileage 79.80 and 80.69, Ontario.

16724—June 4—Approving plans of G.T.P. Ry. for freight shed at Mission Terminals, Fort William, Ont.

16725—June 11—Approving plan of C.P.R. (G. B. & S. Ry.) for interlocker in swing bridge over Trent Canal, mile 44, Ont.

16726—June 13—Approving plan of Kettle Valley Ry. for 250-foot deck-span over Trout Creek, near Penticton, B.C.

16727—June 8—Authorizing G.T.P. B.L. Co. to open for carriage of traffic its Tofield-Calgary Branch from Red Deer, mileage 83.5 to Trouch, mileage 121.4, Alberta.

16728—June 10—Authorizing G.T.R. and approving stress sheets of Bridge 189, and No. 77 Northern Division and Ottawa Division, Ontario.

16729-30—June 10—Relieving V. V. & E. Ry. from erecting and maintaining fences from Blaine to Colbrook, and from Colbrook to Brownsville, British Columbia.

16731—June 11—Extending until July 15, 1912, time for C.N.R. to put tracks at Saskatoon, Sask., in good shape, etc.

16732-33-34—June 11—16735—June 10—Directing Dominion Atlantic Railway to within 60 days to install improved type of electric bells at four street crossings in town of Windsor, N.S. 20 per cent. of cost of same from Railway Grade Crossing Fund.

16736—June 11—16737—June 13—Approving revised location of C.N.O. Ry. through Township of Torbolton and Fitzroy, Ct. Carleton, Ont., mileage 27 to 37.01 from Ottawa; and through Twps. of Fitzroy and Onslow and Bristol, Ct. Pontiac, Que., mileage 36 to 40 from Ottawa, Ontario.

16738—June 14—Authorizing C.N.O. Ry. to construct across Leamy Creek, Twp. of Nepean, Ct. Carleton, Ontario.

16739—June 12—Approving revised location of C.N.O. Ry. through Twps. of Barrie and [illegible] Lots of Nipissing, Ontario.

16740—June 12—Authorizing C.N.R. to cross with its Vonda Northerly and Tramway to Saskatoon, Sask.

16741—June 11—Authorizing G.T.P. Railway to construct across highway mileage 194.8 Cassiar District, B.C.

16742—June 13—Approving location of G.T.R. new station at Stratford, Ontario.

16743—June 14—Authorizing Campbellford, Lake Ontario and W. Railway (C.P.R.) to cross two highways in Twp. of East Whitby.

16744—June 13—Authorizing C.P.R. to construct additional track across highway at mileage 107.38 on Cascade, S.D.

16745—June 12—Authorizing C.P.R. to reconstruct bridges Nos. 17.0 and 17.9 on Swift Current, S.D.

16746—June 15—Relieving C.P.R. from further protecting crossing of Main Street, Walkerton, Ontario.

16747—June 15—Directing Central Vermont Railway to extend its siding at Stone, Que. Complaint Shippers of N. Stanbridge, Que.

16748—June 17—Authorizing G.T.R. to construct two sidings across William Street, Kingston, Ontario.

16749—June 8—Authorizing C.P.R. to take lands at Leaside Junction for new station site, etc., and approving new station site.

16750—June 13—16751—June 11—16752—June 13—16753—June 14—16754—June 13—Authorizing C.P.R. to construct spurs for following:—Alaska Bedding Company, Regina, Sask., J. McDiarmid Company, Calgary, Alta., American Lumber Company, Sumas, Jct., B.C., Canadian Sardine Company, Chamcook Station, N.B., Saskatoon Lumber Company, Saskatoon, Sask.

16755—June 14—Authorizing C.P.R. to construct two additional tracks across road allowance at mile 176.57 Calgary, S.D.

16756—June 14—Rescinding Order 16713 June 8, 1912, and authorizing C.P.R. to open for carriage of traffic its double track from mileage 98 at Melbourne to Carberry, mile 106.

16757—June 10—Extending until July 15, 1912, time for C.P.R. to complete fencing ordered by Order 15864 February 1st, 1912.

16758—June 15—Authorizing Campbellford, Lake Ontario and W. (C.P.R.) to cross 12 highways Twps. Bedford and Hichinbrooke, Ontario.

16759—June 8—16760—June 15—Authorizing C.P.R. to construct bridge 0.3 over Sask. River, Calgary, S.D., and reconstruct bridge No. 124.4 on Muskoka Subdivision.

16761—June 13—16762—June 17—Authorizing C.P.R. to construct additional track across highway at Westminster Jct., New Westminster, B.C., and at Kyle Street, Port Moody, B.C.

16763-64—June 14—Approving proposed changes in location of C.P.R. stations at Plaisance, Que., and Hammond, Ontario.

16765—June 15—16766—June 13—16767—June 13—16768—June 10—Authorizing G.T.R. to construct spurs for British Canadian Canners, Limited, Cobourg, Ontario, Dain Manufacturing Company, Limited, Twp. of Humberstone, Ontario, The London Concrete Machinery Company, Limited, London, Ontario, Alaska Feather and Down Company, Limited, Montreal, Quebec.

16769—June 11—Authorizing G.T.R. to reconstruct bridge at M.P. 20.56 on 22nd. Dist., Twp. of Waterloo, Ontario.

16770—June 13—16771—June 15—Authorizing G.T.P. Railway to cross highways (2) in Cassiar and Coast Districts, British Columbia.

16772—June 8—16773—June 15—Authorizing G.T.P. B.L. Company to construct station at Prongua on its Cutknife Branch, Saskatchewan, and approving location of station at Rowatt, Saskatchewan.

16774—June 13—Authorizing G.T.P. Railway to cross highway at Mileage 90.5 District of North Alberta, Alberta.

16775—June 17—Authorizing G.T.P. B.L. Co. to take possession of C.P.R. land for right-of-way, Tofield-Calgary Branch.

16776—June 10—Authorizing Algoma Eastern Ry. to construct swing bridge at Little Current, between Goat and Manitoulin Islands.

16777—June 17—Authorizing Algoma Eastern Ry. to connect with C.P.R. (Soo Branch) and Huronian Spur of Canadian Copper Co., in Twp. of Drury, Ontario.

16778—June 11—Authorizing Algoma Central & H.B. Ry. to cross highway between Cathcart St. and Wilde Ave., Tagena, Algoma, Ont.

16779—June 11—Approving plans of subway at Jasper Ave., and bridges at McKay and Victoria Avenues, Edmonton, Alta., C.P.R.

16780—June 10—Authorizing C.N.O. Ry. to cross 8 highways in Twps. of Ross and Westmeath, County of Renfrew, Ontario.

16781—June 15—Authorizing C.N.O. Ry. to cross Nicholas Creek, in Township of Marlborough, County of Carleton, Ontario.

16782—June 17—16783—June 13—Authorizing C.N.R. to cross with its Alsask, S.E., 13 highways, and with Swift Current Extension, 6 highways, in Saskatchewan.

16784—June 8—Approving by-law No. 12, British Yukon Ry., authorizing O. L. Dickeson, president, to prepare and issue tariffs.

16785—June 15—Approving clearances for V.V. & E. Ry. dock and warehouse at Burrard Inlet, British Columbia.

16786—June 14—Authorizing T.H. & B. Ry. to construct spur into premises of Geo. Frid Co., Ltd., Hamilton, Ontario.

16787—June 10—Authorizing Vancouver, Nanaimo Coal Co., to use and operate bridge where it crosses Esquimalt & Nanaimo Ry. Mountain District, Vancouver Island, B.C.

16788-89—June 15—Authorizing C.P.R. to construct spur for Gorman, Clancy & Grundley, Ltd., Edmonton, Alta., and for Oliver Lemire, Cabane Ronde, Quebec.

16790—June 10—Authorizing C.P.R. to alter location of existing tracks and to make alterations in bridges across Mountain, Aqueduct & Guy Streets, Montreal, Que.

16791—June 13—Authorizing G.T.R. to construct siding for Dominion Canners, Ltd., Simcoe, Ontario.

16792—June 15—Authorizing C.N.O. Ry. to cross McCawley's Creek, in Township of Nepean, County of Carleton, Ontario.

16793—June 17—Authorizing C.N.O. Ry. to construct bridge on land of Thomas Till, Rosebud Creek, Alberta, within 30 days.

16794—June 17—Amending Order 16661, dated March 2nd, 1912, by striking out words and figures, "Minimum charge 15 cents" at end of paragraph 3 of clause (b), to points not over 300 miles distant. Complaint, Manitoba Free Press, Winnipeg.

16795—June 11—Appointing E. Blois, Mayor, New Carlisle, Que., and David W. Mill, Q.L.S., as arbitrators, between Quebec Oriental Ry. and L. J. Riopel, in re payment for lands.

16796—June 18—Authorizing Essex Terminal Ry. Co. to open for carriage of freight traffic its line through city of Windsor, and Twp. of Sandwich West and town Sandwich, Ontario.

16797—June 18—Amending Order 16756—June 15, 1912, by adding words "and the trolley wire and wires" after first word "Tracks" in third line of second paragraph of Order.

16798—June 11—Extending until 1st October, 1912, time for completion by Toronto Eastern Railway of spur to Durham Rubber Company.
